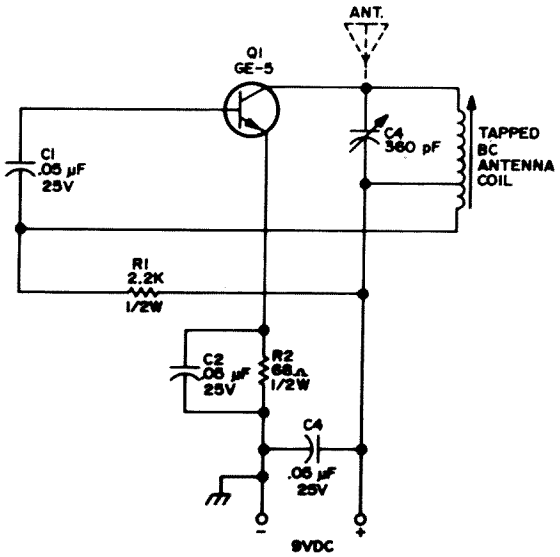
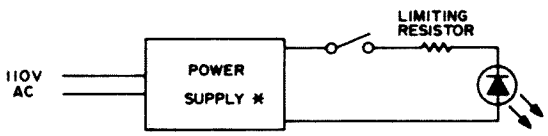
Sometimes when making a tape or reperfing, your supply roll will run out; or you may have a break or tear in a tape. The simple side tear problems are easily fixed with a bit of Scotch tape trimmed to the edge of the tape. Otherwise, you may need a splice or patch. These are not the best solutions, and you should make a copy tape with the repaired portion, but a fairly good splice may be made with white glue to add a fresh roll to one that is running out. Overlap about an inch or so. Be sure the glue is dry (I use my lighter carefully to hasten drying). You can also punch a short piece of tape with the same characters and splice a bad spot in the middle of the tape. With the chadless types, they may be merely run together in the TD to hold the splice. But if you want to keep the tape for any time, take the time to make a new one.

When running a long tape on the air, don't forget the need to ID at least every ten minutes. If you have the narrow shift CW ID facility, that is fine and will lock up most of the machines. In the absence of the narrow shift (about 100 cycles), stop the TD and let the steady mark tone stay for a few seconds, then CW ID and repeat the steady tone to permit the other fellow to hit his standby switch and not interrupt his print. When making tapes, do make them as short as possible and leave out all those lines across the paper that are in some brag tapes, the "CW ID follows" bit and similar unnecessary characters or language.



So get all that tape off the floor, men. You may even find something you lost long ago.

. . .WA6PIR

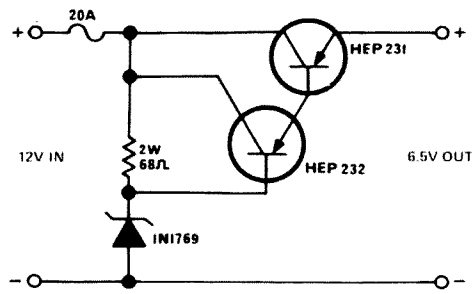


CIRCUITS, CIRCUITS, CIRCUITS...

The following circuits have appeared in the referenced books, magazines, application notes, etc. While we try to reproduce all of the information that should be needed by an experienced constructor, readers may want to avail themselves of the original sources for peace of mind.

Readers are requested to pass along any interesting circuits that they discover in sources other than U.S. ham magazines. Circuits should be oriented toward amateur radio and experimentation rather than industrial or computer technology. Submit circuit with all parts values on it, a very brief explanation of the circuit and any additional parts information required, give the source and a note of permission to reprint from the copyright holder, if any, and the reward for a published circuit will be a choice of a 73 book. Send your circuits to 73 Circuits Page, 73 Magazine, Peterborough NH 03458.

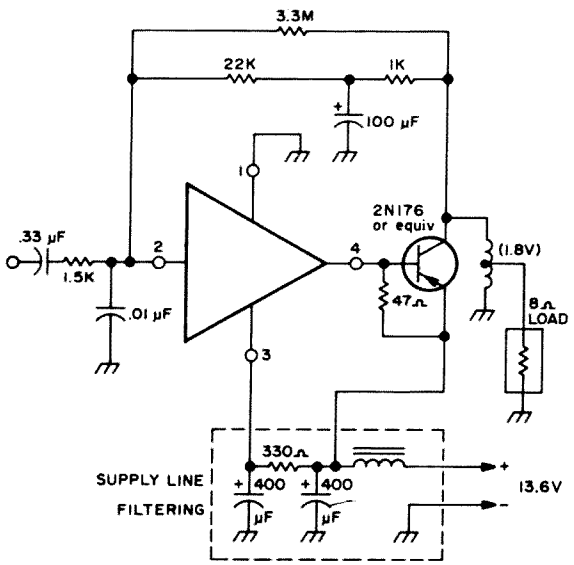
Beat frequency oscillator (courtesy of Gerard Piette, Ontario, Canada). Place unit near receiver and tune C2 until SSB and CW signals become intelligible.



* IF POWERED FROM THE AC LINE, THE OUTPUT MUST BE 6 VAC (STANCOR TRANSFORMER NO. P8385 OR EQUIV). OTHERWISE, POWER SUPPLY IS 6 VDC AT 100 mA.

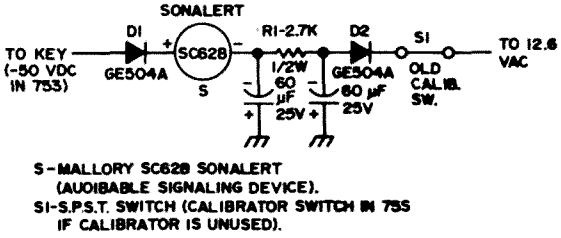
LIMITING RESITOR CALCULATIONS

$$\frac{V_S - V_F}{I_F} = R \text{ (min.)}$$

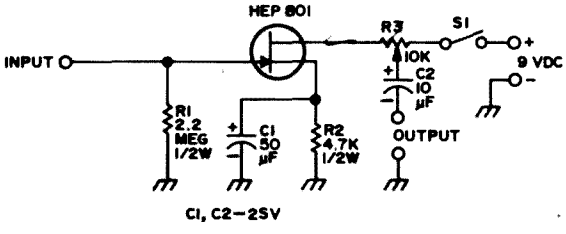


V_S = SOURCE VOLTAGE
V_F = LED FORWARD VOLTAGE
I_F = FORWARD CURRENT
R (min.) = VALUE OF RESISTOR (in ohms)

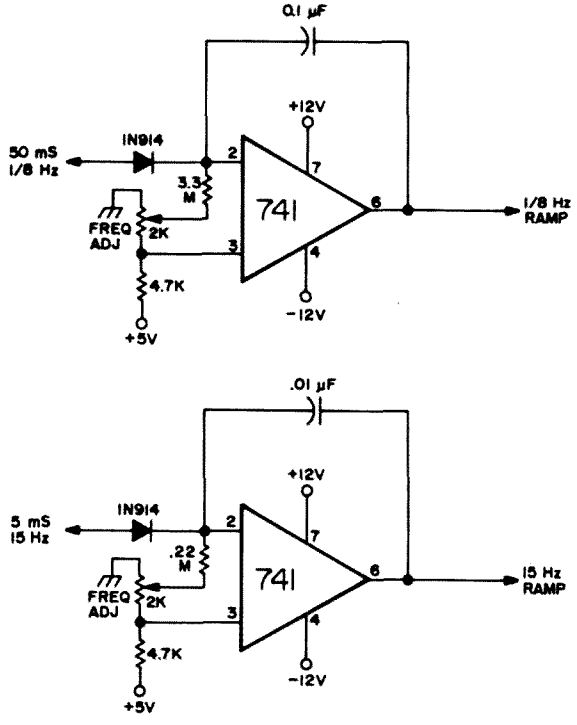
The power requirements for light-emitting diodes are very low and the devices may be operated from a variety of power sources. However, it is necessary to limit the current to an LED, since, like a neon lamp, it can be damaged if permitted to draw excessive current. The simple formula will help to determine the correct resistance value. Courtesy Sprague Products Co., L.E.D. Application Notes.



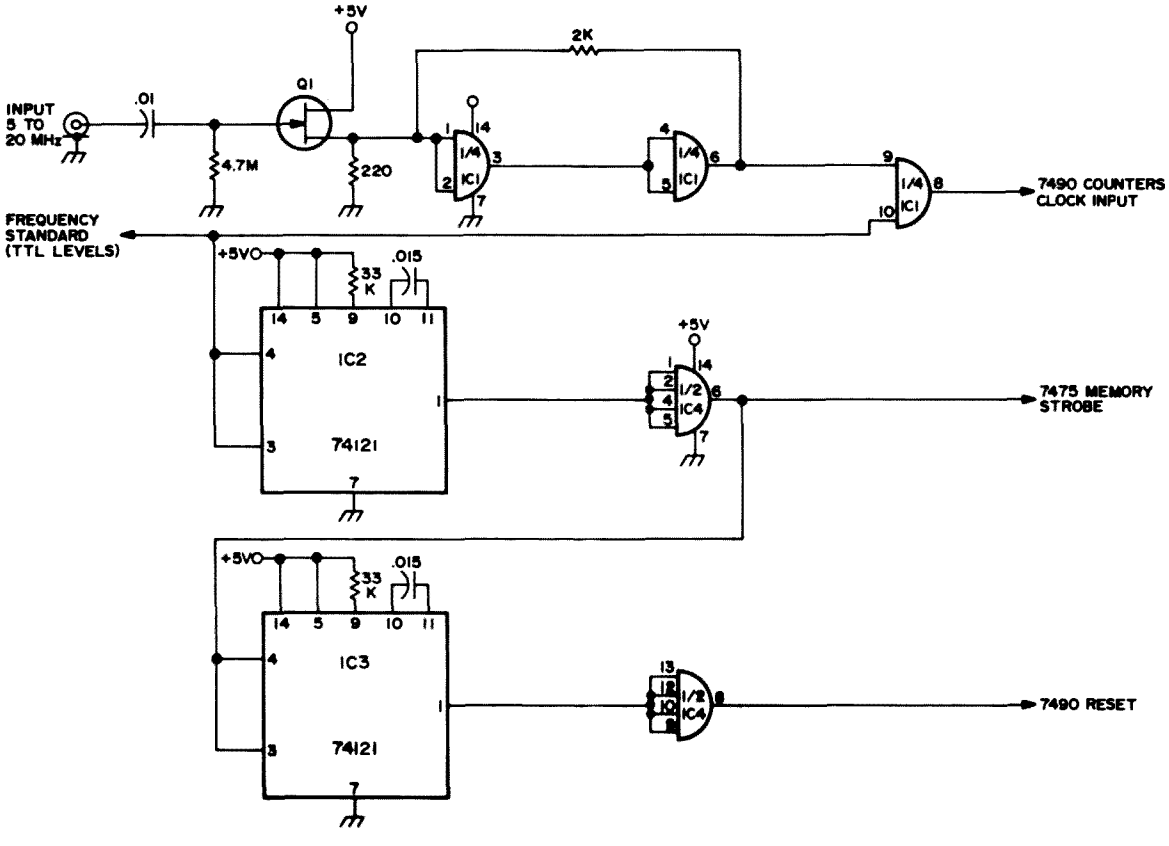
12 to 6 Converter



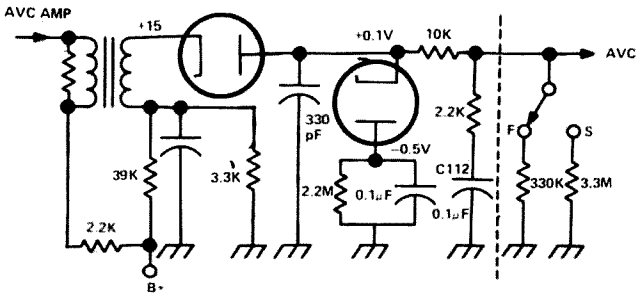
You say you got a real bargain on an old motorcycle FM rig, only to find out it was 6 volt? Fret no more. Below is a handy-dandy 12 volt to 6 volt converter unit, courtesy of KØWRL, which is suitable for low and medium powered gear. The transistors should be mounted in a suitable heat sink. From Grid Leak, Pueblo, Colorado.



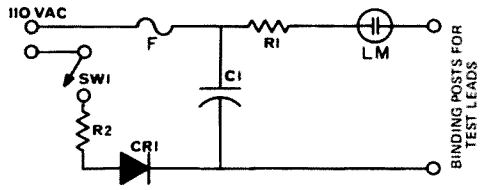
Typical 4 watt amplifier circuit application of a Motorola MFC4050 silicon monolithic functional circuit, a Class "A" audio driver designed for driving Class 'A" PNP power output stage applications. Circuit courtesy of the Motorola Functional Circuit Handbook.



CW sidetone using Mallory SC628 Sonalert. For positive key voltage, reverse all polarities. (Thanks to Alex Szablak, New Hartford NY.)



Microphone preamplifier. Mike output low? Fix it with this one. This is for use with a ceramic or crystal microphone or even a phone cartridge. Circuit courtesy Motorola HMA-33 Tips on Using FETs.

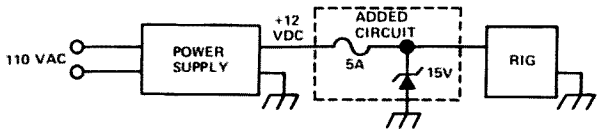


SSTV ramp generators. This circuit will give an extremely linear ramp for SSTV monitors, cameras, and flying spot scanners. The voltage varies from ≈ -10 to +10. A positive going pulse of +2 to +5V amplitude resets the ramp for the next sweep. (Thanks to WØLMD)

Frequency counter input: gating, strobing and resetting. The sensitivity is set by the ratio of the 220 to 2K resistors. (Thanks to WØLMD)

AVC modification for better SBB reception with the Collins 75A4 that lets you leave the rf gain wide open. It gives much longer AVC time constant and prevents audio "pumping" on speech. Change C112 from 0.1 μF to 1.5 μF mylar, 100V.

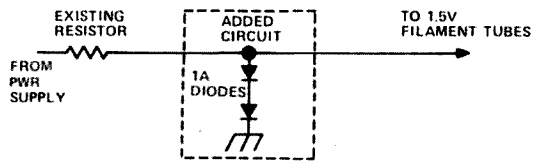
When testing a capacitor, the light will blink once or twice while the plates are loading and then will remain off. If the capacitor is not good, the light will continue to blink.



When checking capacitors wired into circuits, one end must be disconnected.

R1 – 47K 2W resistor, R2 – 330K 2W resistor, LM-1 – Neon lamp NE 51, C1 – 8 or 10 mic capacitor 450V dc, CR1 – 1M3611 diode (not critical), SWL – ST toggle switch, F – ¼A fuse.

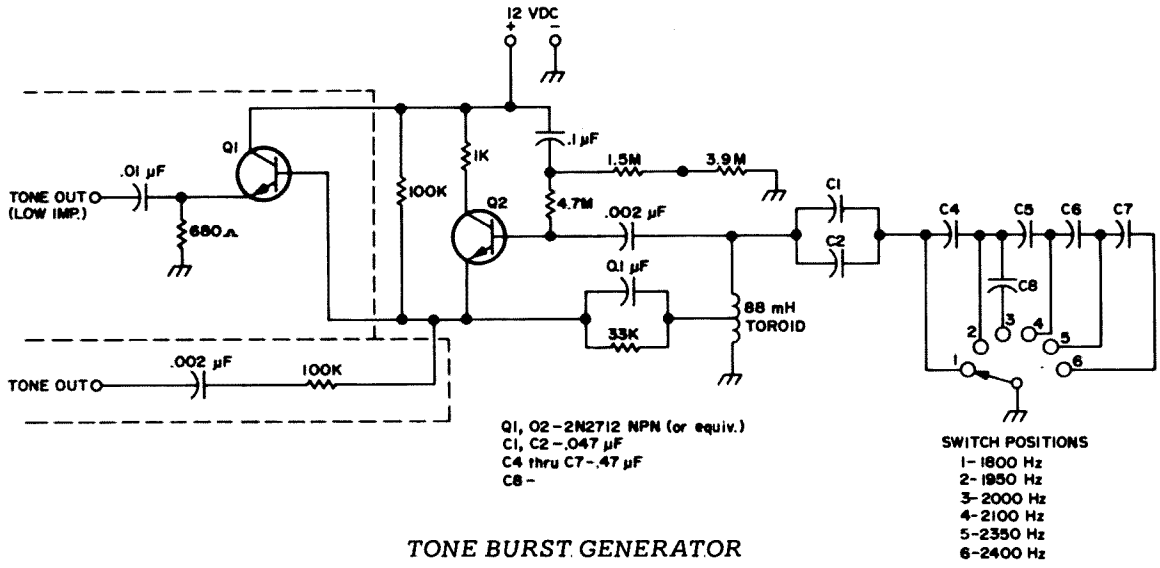
From the Colorado/Wyoming MARS Newsletter.



FOR YOUR OWN PROTECTION

Since everything fails at some time or another, thought should be given to what would happen to one of those solid state transistorized rigs should the line operated 12V supply fail. Many times when a supply fails, the output voltage rises to much greater than 12V. The results, as you can imagine, are disastrous, as several people have discovered. Therefore the following circuit is recommended to be used whenever operating from any non-battery supply.

The zener should be at least 1W and preferably 10W.



Along these lines, the following circuit can help to greatly prolong the life of filament type tubes in appropriate sets (H23, P33, MRT-9, etc.) when operating from supplies other than dry batteries. Some sets have two limiting resistors or balast tubes, one for receive and one for transmit. In this case, two of these diode sets must be used.

Circuit by Alan Tasker WA1NYR, reprinted from WA1KHB MRA Newsletter.

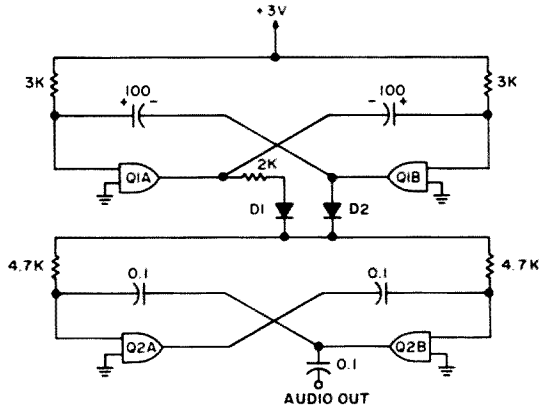
TONE BURST GENERATOR

Tone-burst entry is becoming increasingly common as a requirement – repeaters in many parts of the country now require anything from 1800 Hz to 2400 Hz for entry. The circuit above is for a tone-burst generator to meet these requirements. Circuit courtesy of the Central Ohio Radio Club FM News, September, 1971.

TM - THERMISTOR, VECO 35C1 or equiv. (5K COLO)

$$f_{OUT} = \frac{1}{2\pi RC} = \frac{.159}{RC}$$



IC1 - MC1458P

A SIMPLE SINE WAVE GENERATOR

There are several applications where a good pure sine wave is useful such as a two tone test device for sideband rigs, sending CW with a phone only rig, etc. The Wien bridge circuit is one of the best and simplest methods of getting a good sine wave. In most Wien bridge oscillator circuits using integrated circuit op amps, very small values of R had to be used in the bridge because of the low impedance inputs of these devices.

In this circuit, the parallel branch of the bridge is connected from the inverting input to the output of one of the two op amps; thus it sees a very high impedance. The amplitude control is shown as a bead thermistor; however a 10K pot could be substituted as shown or any other method of output level countrol could be used. For a frequency of 1 kHz, R=330K and and C=470 pF.

The Motorola MC1458P, National LM1458, Signetics N558V and TI SN72558P are all identical and may be used above with no modifications. The Fairchild µA747 may also be used but leave the offset null terminals open. Two 741's are also suitable. If you use 709's you may have to include frequency compensation as all of the above mentioned IC's are internally compensated. (Circuit by Roger WB6ESP, reprinted from The Footprint, Foothills ARS, Mountain View CA.)

D1,D2 = 1N34 or other germanium.
Q1,Q2 = µL914 or equivalent.

Circuit shown above provides a square wave output from Q2 whose audio frequency is changed alternately by action of multivibrator Q1. The resulting warbling note provides an excellent burglar alarm or hidden transmitter signal. Circuit submitted by J.F. Walker W6GNL.

ELLIPTIC FUNCTION FILTERS FOR RTTY

Most newcomers to radio teletype encounter similar types of problems which they experienced in single-sideband and CW signal reception. One such problem is that of selecting the desired signal from the unwanted noise in the channel through the use of suitable filtering.

The purpose of this article is to provide design information that will enable the average amateur to build a good set of channel filters for RTTY at modest cost. The filter to be described was chosen because of its inherent sharpness and ease of tuning. Other design configurations, such as the Butterworth and Tchebycheff, have been used successfully but perform less satisfactorily than the elliptic function type when it comes to skirt steepness.

The sharper skirt characteristic is readily apparent when the two types are compared as exhibited on Graph 1. Shape factor and band width help to maximize the signal-to-noise ratio. The graph compares the six-pole Butterworth filter described in *RTTY*

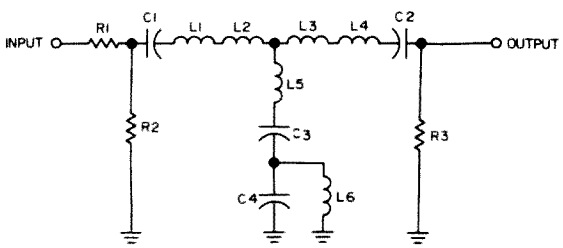

Fig. 1. Elliptical function filter.

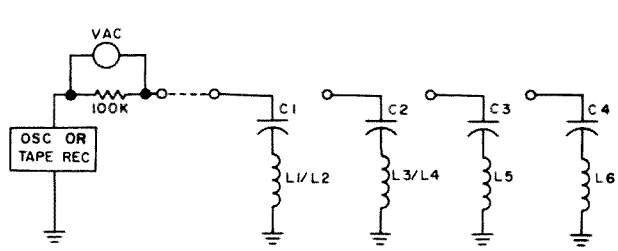

Fig. 2. Test jig for tuning filter elements.

TABLE 1

Frequency	C1, C2	C3	C4	L1-5	L6	R1, R3	R2
2125 Hz	.032	.072	3.3	88	1.67	150	200
2295 Hz	.028	.047	3.0	88	1.80	150	200
2550 Hz	.025	.047	3.2	88	1.24	150	200
2975 Hz	.017	.034	3.5	88	0.81	150	200

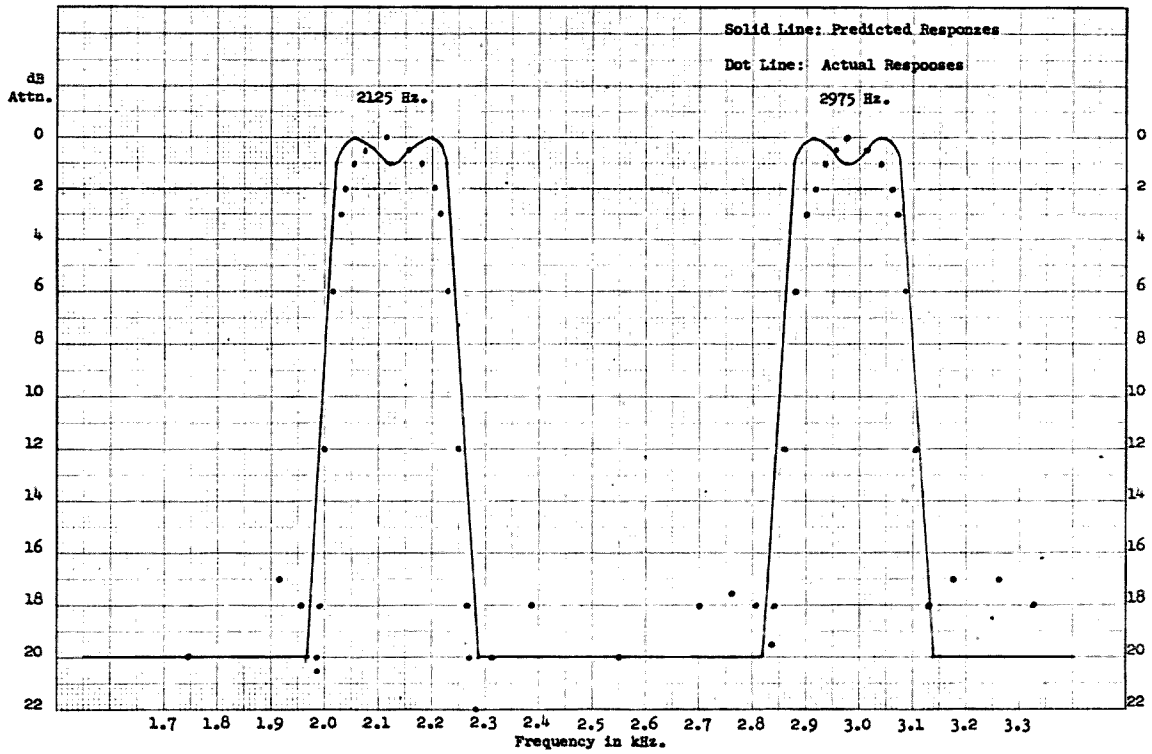
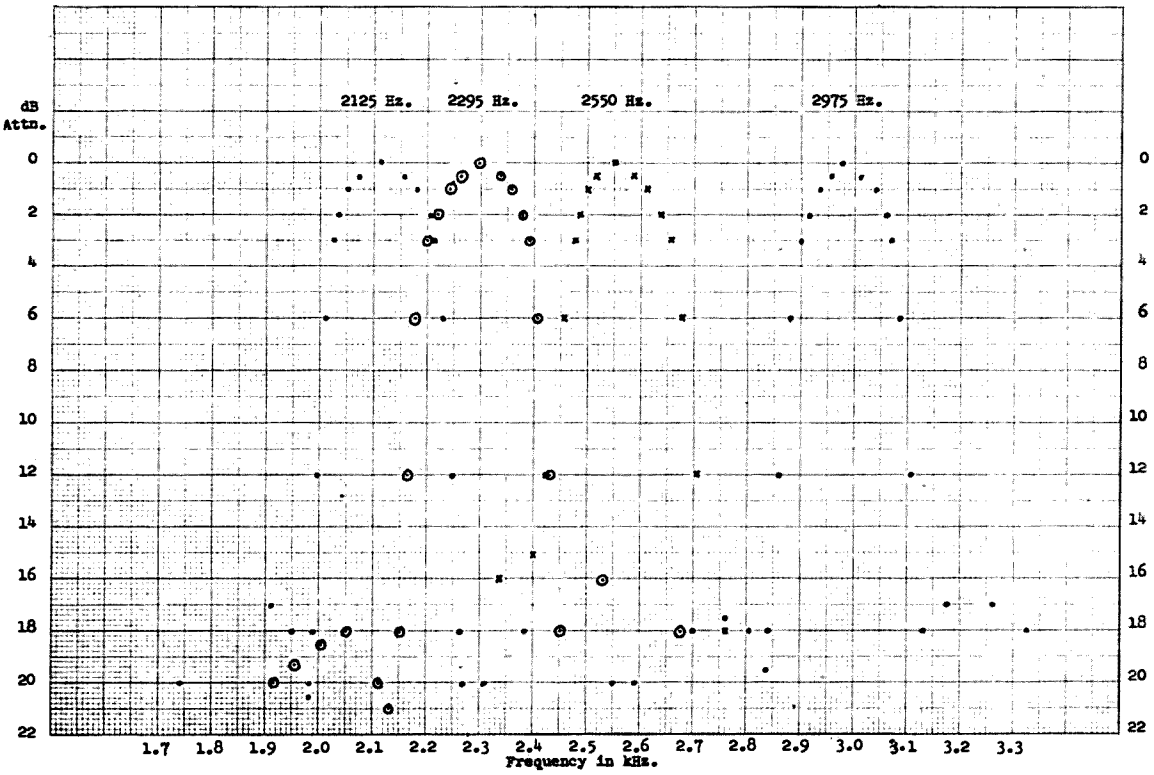
Journal, November, 1966, with a four-pole elliptic function filter of modern design.

There are basically two types of terminal units in use by amateurs. One type employs a linear discriminator while the other uses a clipper or limiter circuit. A narrow-band filter offers only about 1 dB improvement over a broadband filter when used in a discriminator type terminal unit. If a terminal unit uses a combination of both an FM and a linear system, then the narrow-band filter is the most desirable as the linear system is enhanced by its use.



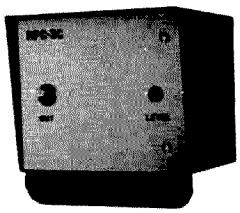
A linear system works best on single or dual channel copy when the signal is exhibiting a slow multi-path fade. The limiter type system responds best to signal flutter or quick, shallow fading to which the limiter seeks to maintain a constant level of output.

Construction of Broadband Filters



For some reason, there is not too much specific information available on RTTY filters for amateur use. Digital and other types of active filters are being designed from time to time but their cost and more involved circuitry usually tend to make amateurs rely on the simple passive types of filtering. The article in *RTTY Journal* provided the impetus for me to duplicate the filter set employed in the AN/FGC-1 military terminal unit. Sufficient test equipment was available to accurately measure the response of the constructed filters with a net result of remarkable adherence to the response curves provided. This was gratifying, to say the least, as there were many difficult component values to "bridge out." The filters were constructed on Vectorboard using 88 mH torioids in series to provide the large inductances which were required. The resulting 850 Hz broadband filters offered a good start toward a respectable terminal unit. The major drawback to using the filters is that considerable operation today is on narrow shifts of 170 Hz or 425 Hz. For this reason the construction of a new set of narrow-band filters was begun..

Graph 1. 6-pole Butterworth compared with a 4-pole elliptic function filter.



Graph 2. Predicted responses and actual responses of 2125 Hz and 2975 Hz filters.

Graph 3. Actual responses of all four filters.

Designing Elliptic Function Filters

One of the best sources of filter design information is found in "Simplified Modern Filter Design" by Philip Geffe. A computer was used to derive tables provided in Geffe's book which greatly simplified the calculations involved. The simplest and sharpest elliptic function filter was selected and the design was made with due consideration given to the availability of parts.

The basic design of the elliptic function filter is shown in Fig. 1. All of the filters for 2125 Hz, 2295 Hz, 2550 Hz and 2975 Hz, use this configuration.

The equation used predicted a 1 dB ripple in the passband and 1 dB down on the slopes at 200 Hz wide. The actual lack of ripple in

Graph 4. 88 mH toroid: approximately 168 mH/1000.

the passband of the constructed filters may have been caused by insufficient Q. The predicted response curves for the elliptic function filters are shown in Graph 2. This graph has the response plotted for two filters with 850 Hz separation, namely 2125 Hz and 2975 Hz. Equally sharp responses were obtained for the 2295 Hz and 2550 Hz filters. Also shown on Graph 2 are the actual curves of the constructed filters. A frequency counter and ac voltmeter were used to accurately plot the responses. As can be seen, the actual filter responses were slightly narrower than the predicted responses. This presents no serious drawback to the system, however.

Narrow-band filters will not tolerate much signal drift but with today's modern receivers and afc circuits, drift is greatly minimized anyway. Parts layout is not critical but good quality capacitors must be used throughout the circuit or serious degradation of the response will be experienced. Do not use electrolytic capacitors.

Table 1 indicates the values of components required for each filter. Some padding of the standard values will have to be done to obtain the values shown.

The Ubiquitous Toroid

The 88 mH toroid inductor was employed wherever possible because of its acceptable Q and low cost. Only one inductor in each filter is not the standard 88 mH value. This is not too serious a problem, however, as will be shown later. Several 88 mH toroids were measured on a General Radio Impedance Bridge. The average inductance was calculated to be 86.8 mH. Further measurement indicates that the core of the 88 mH toroids has a permeability of approximately 168 mH per 1000 turns. This means that, by using logarithmic graph paper, a simple method of determining the number of turns required for a particular inductor can be achieved. A graph is presented for those amateurs who may find the information helpful in building the elliptic function filters or other filters.

Tuning the Filters

The most efficient way to tune each filter would be to use a calibrated frequency

(b) 6-pole Butterworth broadband.
Fig. 3. Oscilloscope patterns.

generator and counter, along with a sensitive ac voltmeter. Not all amateurs have access to such equipment, but with a little resourcefulness, good results can be obtained. Try to find someone with a calibrated oscillator who will tape record about a foot or so of each desired frequency. Make a continuous loop out of each foot-long tape and play back the tape while feeding the tape recorder output (4Ω) into the filter circuits being tuned. Using the method shown in Fig. 2, tune each combination of elements to the desired center frequency. This will be indicated by a *peak* in the output level. Removing a few turns from each inductor may be necessary to get exactly on frequency. Padding with capacitors is much more difficult to do and the slight change in inductance won't severely affect the filter impedance.

Termination of Impedances

The input impedance of the filters is designed to work from the 4Ω speaker output of most receivers. A 600Ω receiver output may be connected directly to the

filters by eliminating R1 from each filter. The output impedance is 150Ω. These impedances were chosen because of the desire to use the standard 88 mH inductors. Different impedances will require different inductors. There is about a 6 dB loss through the filters. Amplification may be required between the filters and the terminal unit if diode rectification is to be used.

Results and Findings

A comprehensive graph of all four filters is shown in Graph 3. It can be seen that the minimum channel separation between the 2125 Hz and the 2295 Hz filters is approximately 3 dB. Separation between other combinations of filters approaches 20 dB.

Oscilloscope patterns in Fig. 3 compare the familiar cross patterns used for tuning in a typical RTTY signal. The Butterworth filter pattern has a more oval shaped trace while the elliptic function filter pattern is almost a straight line. The Butterworth broadband filter allows more noise into the channel which may capture a limiter or otherwise interfere with the signal.

Conclusions

Good, sharp, narrow-band filters for RTTY can be constructed by the average amateur using inexpensive components and having limited access to sophisticated test equipment. Simple duplication of the theoretical filter design should yield the results obtained in Graph 3. More complicated designs will offer better solutions to signal-to-noise problems. This will no doubt increase the cost of constructing such filters and complicate their tuning. The lack of access to sufficient test equipment may preclude most amateurs from attempting to build such devices. There should, however, be continuing research performed in these areas by amateurs for amateurs.

There are four persons to whom I am indebted for their assistance in making this report a reality: Richard G. Coalter for his engineering talent, Dennis M. Pierce for his report-writing skills, Vicki Spraggins for her typing and patience in retyping, and Eric Sager for making me find the time to get it all together.

Step on the KLUTZ i

The question, "What's 'he' (meaning me!) doing in a 'ham' magazine?" is quite often asked.

The answer? Simple, really! Amateurs aren't all transistors, antennas and microfarads. They are real, honest-to-goodness individuals. They're interesting, inventive, sincere and ofttimes very funny people!

Some amateurs are electronic wizards, others are dexterous with key, bug and mill or have the unique ability to converse endlessly on a myriad of subjects and, of course, as in other fields, some are *klutzes*.

Every ham possesses some of these qualities – only the degree of proficiency varies.

When a ham blossoms forth, he becomes an authority in that area in which he excels and, as an authority, has a right to be heard and discussed.

Those of you who have followed my literary gamboling from "In the Beginning" to "Bob, Bob, Bobbin' along" know that I derive my material from personal experiences, and my forte is that I'm a *klutz*!

My soldering iron either refuses to melt the solder or sets fire to the whole damned bench, my hot-melt glue-gun delights in oozing glue onto the floor in a messy puddle to which my feet seem to be irresistably drawn (on at least two sticky occasions I thought I was paralyzed). Right now – as mute testimony to this fact – there are two shoes, an old sneaker, and one argyle sock stuck to the floor under my work bench.

At the operating position, my earphone-microphone always precedes my tongue into the coffee cup and the lumps on my forehead from banging into desk tops while reaching over for dropped articles are legendary.

On RTTY I say, "Hold up – gonna change ribbon!" I reach in my hand only to retrieve it with "RGR OM" stamped indelibly on my thumbnail.

In public, someone seems always to be just milliseconds ahead of me either causing spring-loaded doors to whomp me into semi-consciousness, or they've just stopped their dogs – leaving a meadow muffin – in the exact spot where I, in less than 1.5 seconds, will put my size 10 clodhopper.

Spray cans are my particular nemesis. If the can rattles before my wrist atrophies and the nozzle doesn't clog, then I somehow manage to reverse the spray head sending half a can of black lacquer or *Raid* up my sleeve. I've got a dozen shirts with dazzlingly colored right sleeves, my underarm looks

like the NBC peacock and I can exterminate half the bugs in New England with a single salute!

Those of you who use typewriters know how easy it is to stick your fingers between the keys, but have you ever gotten a digit firmly stuck there? I have! Had to wrap that 50 lb Remington up in a baby blanket, fasten a mock nursing bottle near the top, and smuggle myself into the emergency room – mumbling to interested onlookers that the 'baby' has colic.

Then, in the examining room when I remove the blanket, exasperatingly jabbering an unheard explanation to a doctor, nurse and several corpsmen – all of whom are doubled up in helpless, convulsive, hysterical and tear-spilling laughter – as to how it all happened.

Okay, so you can send and receive 35 wpm or build a heat-activated 2 KW SSB transceiver no bigger than a match head. Well, I'm a *kultz*! That's my specialty – pure and simple. Who, then, is better qualified to point out the absurdities in hamdom than I?

My warped sense of humor only complicates the situation. I'm not intentionally sacrilegious – it just happens. Example: You're familiar with the phrases, "right 'hand' man," "The 'voice' of America," that police use 'leg' men, that reporters have a 'nose' for news. Fine. Now how about the ham magazine that bills itself as an "Official Organ?" I apologize, but every time I see or hear that phrase, my cracked psyche never fails to conjure up a giggle-producing mental picture. What's an "Official Organ?" The hams' ambassadorial stand-in stud with portfolio, sash and badge perhaps?

Based on the foregoing, I can assure you that the next few pages will definitely not be devoted to laborious and somewhat dubious methods of converting your toaster, sump pump and/or athletic supporter to 2m FM; nor will it render any advice on CB rig modification (albeit, I do have some poignant – if somewhat improbable – suggestions on what could and should be done with those over-modulated, 23-channeled, 27 MHz miscreants but I'm somewhat reluctant about openly diagramming them. The last time these anatomically improbables were expressed, they unintentionally influenced a contortionist who, as a result, not only filed a paternity suit, but billed me for postpartum care and I became the unwilling godfather to a cesarean Johnson Messenger II. I don't know what the guy was complaining about – what with the built-in mini-whip he had a perfectly functional curb feeler, paper-picker-upper and midget stabber.)

Neither will my latest literary faux pas delve into the realm of 'gimmicks.' For, to me, the only authentic "Automatic Nut Starter" is the jerk who hands a microphone to a Citizen Bander!

Before you jump to any erroneous conclusions, let me assure you that I have nothing against CBers – per se – even though it has been said that it would be apropos to define gross incompetence as a herd (a mob has a leader) of Citizen Banders armed with screw drivers. Anyhow, anyone who's unfortunate enough to have his tongue and colon joined so closely together deserves understanding, not criticism! I won't comment on the quote uttered by one learned gentleman who stated that a ham was nothing more than a Citizen Bander who had discovered a second use for his fist! . . . ah, well.

This article will consider the inane object, "Why does society view hams through traumatic and jaundiced eyes in much the same way that would observe an anti-social and not-quite-housebroken hippopotamus?" The *klutz* factor seems to overshadow all else.

Experience has taught me, after having it mentioned on several diverse occasions – which resulted in my being stepped on by Gentle Ben, kissed by a yeti, tossed summarily out of a friendship club, deliberately run down by a Welcome Wagon and mugged by a Good Humor Man wearing a peace symbol – that you should never voluntarily admit that you are, indeed, a ham!

[Small aside: Rapid calculation with my 98¢ Magi Brain Calculator shows that hams comprise only 1/1000th of the population. This makes us a very minor ethnic group whose acceptance by society would be greatly advanced if there were more hams.]

Therefore, I block-letter crayoned a brief note to the FCC urging "LOWER YOUR REQUIREMENTS!" to which they replied, "UP YOUR FREQ!"

Certainly anyone who's been a radio amateur for any length of time is all too familiar with the warning signs that precede the announcement that you are unacceptable. However, for those who aren't familiar, *beware*!

The first, most common and easiest to recognize reaction to hams by non- or anti-hams is an apoplectic facial contortionistic look – or GAWK – of sheer horror. Picture if you will Harry Greedy-Gut at a buffet supper, one hand full of canapes, the other clutching cookies. Spying some new delicacy he gulps down the canapes and reaches for the newest goodies, only to find that he has inadvertently swallowed someone's pocket watch. In frenzied horror he'll 'drop his cookies' and his expression will reflect unbelieving shock which will decrease only with the passing of time.

Chance observances like this are rare to witness and are, for all practical purposes, indescribable. The GAWK can, under certain controlled environmental circumstances – and only for familiarizational purposes – be closely simulated.

You can, for instance, don a tri-colored beanie, replete with propeller – grasp a full grown, malodorous and recently agitated polecat by the tail, wave it over your head and, with a purple popsicle stuck in your left ear, stomp through the largest department store in town plucking a three-stringed swinette and humming the first eight bars of "I Wanna Be Loved By You!" – or –

You can dash stark naked into a meeting of the local D.A.R., screaming "I'm a reincarnation of Paul Revere! Where's my pot? The guy in the steeple was a pyromaniac. One if by land, two if by sea; one lantern two lanterns; land-sea-air, hell! I don't know who or what's coming 'cause he burned down the whole ruddy church!" Then, slithering up to the chairwoman, whisper, "Ya know John Paul Jones was a Russky, Ben Franklin was a bookmaker and Johnny Appleseed was a litterbug . . . "

It may well be that because I am the titular head of a household comprised exclusively of anti-hams I've become overly sensitized – perhaps, as a *klutz*, I bring it on myself.

Gorgo, my XYL (Miss Vitriolic 1939–46), firmly believes that hams, left-handed pitchers and out-of-State drivers are all self-made men who (though perfect models, providing someone wanted to mold an idiot) quit work too soon and had nothing to work with except a superabundance of silly putty and chitlin's. That they would, therefore, join the nearest and most readily accessible chapter of W.O.W. (Witless Old Winos – not a bad group, actually. They send a bottle of Muscatel, a can of sterno or a jug of Aqua Velva with a slice of bread to a friend on Prohibition Repeal Day – it's called a Win-O-Gram!)

Although my crumb-grabbing, curtain-climbing jam-handed vidiot harmonics think it's great fun to invade my shack and in my absence steal pencils, paper and, in short, give the place the appearance of having been hit by several Molotov Blivets, they, at the tiniest flicker on any one of our mandatory 36 TV sets, set up a screaming wail of "Daddy's doin' it again – he's screwin' up Bozo" that can be heard for miles.

This disrespect is not the exclusive property of homo sapiens. It is shared, on at least a part-time basis, with the animal kingdom. I'm not too sure about inanimate objects yet, but I swear I've been karated by doors, tripped by tables and maliciously attacked by the recliner/rocker although Gorgo says that's foolish 'cause the recliner and I are totally compatible since we're both slightly off our rockers.

The Manning menagerie presently consists of a Mynah bird, a poodle, two Siamese cats and assorted fish, bugs, newts and . . . I dunno . . . just things!

While I am constantly being bitten by bugs, hissed at by snakes, eviscerated by cats, spit at by fish and the object of whatever it is newts do to show their disdain, I'll discuss only the Bird and the Dog.

Do you know what a Mynah bird is? It is supposedly a feathered creature incapable of thought that can hear, remember and repeat an unlimited amount of words or phrases. . . sort of a winged L.O.!

In reality it has only one real attribute. It can down an ounce of water and food pellets and, in 24 hours, reproduce five times its own weight in bilious bird dung. It's got the

makings of a Vice Director. (Here it is again – campaign slogan: "Being a Director's nice – as for me, I'm for VICE!)

My XYL's Mynah, Gus, is not only a dedicated and confirmed, but positively vindictive, anti-ham.

After ten months of listening to a tape repeat, "Hello there!" he remained unflinchingly mute. Yet after only one visit from an old Navy CW crony (strange individual whose limited vocabulary consists mainly of 15 four-letter words which he can interchange indefinitely and still remain intellectually coherent), Gus, that $70 feather-covered fertilizer factory, selected and committed to memory one foul unprintable suggestive phrase which details an action singularly abusive to one's hat. He reserves it for my 'on the air' time.

"How," I once in frustration asked a dim-witted relative, "do you stuff a Mynah bird?" to which he predictably replied, "Dahh . . . head first, I suppose!"

On the other hand, Fred, our French poodle, has developed not only a rather unique and demonstrative method of expressing his feelings towards ham gear, but I firmly suspect that he's somehow managed to enlarge his storage capacity in order to more dramatically emphasize his point.

By golly, if I ever catch that flaky looking pop-eyed pansy in the act, I'm gonna swooosh him with my CO_2 bottle, freezing him in that three-legged position, and auction him off at the next Op-Art festival as a frozen still life entitled, "Dog With Upraised Leg," or "Coldcocked Canine Critic!" (He might make a demonstrative hood ornament for an Edsel.)

Wanting to be perfectly objective, I must admit that there is some justification for society's apprehension. For while the Joe Normals are perfectly content to go from womb to tomb without making a wave, Joe Ham is busy fouling up the newly-arrived dishwasher in an attempt to determine how it works, dangling from the tippy-top of some elm tree with his pockets full of dikes, vice grips, instruction manuals and a hip-holstered walkie-talkie or, in general, doing something that appears unorthodox.

How do you explain that a ham is, first of all, a unique individual whose need to

communicate is but the end result of an insatiable curiosity, boundless imagination and an uninhibited necessity to express himself?

A ham is really a state of mind. Like the man said, "The mind is like a parachute, it functions best when open!"

It is inevitable that with such an unlimited sphere of interests what sometimes starts out as normal and reasonable often results in a fiasco. Society never sees the success, only the fiasco. To them it's moronic – it's the *klutz* factor!

I've often thought that, instead of the diamond decal, hams ought to adopt a more expressive heraldic coat of arms consisting of a sprig of mistletoe embroidered on a flapping coat-tail floating in a sea of Lavoris (for Pucker Power) with a Latin inscription meaning, "It seemed like a good idea at the time!"

Lemme cite two instances which, even though reasonable at the time, eventually turned me into a *klutz*!

Peek-A-Boo

Having a rather high-pitched voice (it's possible I went from infancy to senility without ever having gone through puberty – my voice has never changed and I never had pimples – even an acne transplant didn't take) I have long envied those operators that come on like Gang Busters, sounding like Big John, Captain Marvel and Boom-Boom Bailey. Their deep basso profundo voices thunder in – even on Sideband – like AM Hi-Fi!

I've studied acoustics incessantly, built a triangular room, used a compressor and even fed my voice through an amplifier with the treble retarded and the bass at maximum with the end result that I still sound like a composite of Johnny Weismueller, Tiny Tim and Truman Capote!

In deference to Gus, my normal operating procedure is to use a set of cans with mike attached, leaving my hands free to pursue my secondary avocation of bending Barbie, Ken and Skipper dolls into obscene poses (I have the better ones bronzed and mounted, giving my ham shack the appearance of a cross-sectional view of a house that – if real – would require the services of a Madam!)'

One evening while in QSO with the head of a disgrunted Amateur Radio group called MUSIC (Mad and/or Miserable Until you Shove I.C.) [it was a boot-leg QSO since, as you know, MUSIC isn't allowed on the ham bands . . . a pun? So shoot me!], suddenly my eyes lighted on a newly acquired 30 gallon green plastic trash can. Aha, I thought, remembering some laws of acoustics, the perfect mini-studio!

Completely oblivious to everything, and without a moment's hesitation, I pulled the trash can over my head and shoulders and began happily discussing my new sound when . . . you guessed it . . . a knock sounded on the trash can.

There are many things that a glib-tongued enthusiast can rationally explain away – lipstick on the collar – that you buy Playboy for the articles – that a 2 KW $1,000 amplifier is an absolute necessity . . . but believe me, and I speak from experience, there is no way you can coherently explain to a tired, unimaginative (now jittery and open-mouthed) insurance salesman exactly what you are doing talking to yourself all alone in a weird little room with a huge trash bucket jammed over your head! Yet it seemed like a good idea at the time!

Where Were You When. . .

Not long ago, as you might surmise, I was doing two things at the same time. First, we'd had a new septic tank installed, and in order to remove the old one it was necessary to pump the contents of one into the other. I'd brought a '62 Rambler up close to the operation. The little Briggs and Stratton pump was chugging merrily away so I installed a dc to ac inverter in the Rambler. It appeared to work, so I climbed out and strategically placed myself between the car and the pump. Whoom! The engine caught fire!

Having learned that in situations like this panic is your worst enemy, I calmly went into hysteria and, with that inspired genius that at one time or another has caused me to be struck by lightning, removed a random finger and put a gigantic elm tree stump into sub-orbital ARC, I unhesitatingly reached for the only immediately available source of liquid (it seemed like a good idea at the time!).

At that precise instant in time that I pointed the outlet hose into the engine compartment, I was made immediately and quite dramatically aware that not only had I 'done it again' but I was making a popular chaos-describing phrase into a 'living legend' and a real life Cecil B. DeMille spectacular!

Startled by the tragicomic results, I dropped the hose, and, in fetal fashion, crouched – alternatively praying for the engine or pump to die, an escape route, or at the very least a poncho or bumbershoot! Luckily I discovered and grabbed an old Huck Finn type straw hat which I inverted over my head for a modicum of protection.

Besides accumulating in the hat and all over my huge frame, the gigantic pinwheel spray whirled up the side of the house, under the eaves, all over my lilac bushes (which, incidentally, have become the most productive, yet strangest smelling, in ten counties). And, as a crowning glory, the spray adhered to one leg of my 75 meter "V" (needless to say, I've received some odd remarks, on and off the air, about my antenna). It seems that my radiated power is directly proportional to the type of QSO. Bull sessions seem to have a marked advantage over normal or net operations.

I caught sight of Fred surreptitiously peering around the corner with an expression on his face that seemed to say, "Haaa haaa haaa, I couldn't have done better myself!" I grabbed the Huck Finn hat and taking as careful aim as I could through that weird rainbow, I let it fly.

Although I missed Fred, the hat passed close by Gus' window, causing him to set up a scalding idiotic laughter-filled chant of, "He did it! – He did it – blankety blank, he did it! He finally did it, sqwuaaak!"

The end result, aside from having to cut the grass in that area almost daily, was that not only am I and the house studiously avoided (even the yellow line in the road is bowed away from our driveway) but we had to sell the car – which wasn't easy!

We were in no position, financially, to trade off the Rambler, but it became an absolute necessity, because even a brass monkey can't drive around in 15-degree-below-zero weather with all the windows open.

We did however manage – 127 cans of aerosol spray later (it was actually 139 cans, but 12 of them went up my sleeve) – with the windows wide open, and on an exceptionally windy day, to unload it. I see it every now and again. They've painted it, but you can recognize it easily enough. Everywhere they park it, a tree grows!

The point, if indeed there is a point, is that as a ham you may be unfairly singled out as an odd-ball, but if it weren't for all you odd-balls, the rest of society would still be thumping dinosaurs on the head with blunt instruments for their evening meal. Be proud of your idiosyncrasies.

TROUBLE SHOOTING FOR THE NOVICE

Sooner or later almost every piece of amateur equipment needs repair. Trouble shooting your equipment can be a very interesting part of your hobby.

The power supply is a good place to learn trouble shooting as the power supply must be working properly before any other part of the equipment can be checked.

The power supply may be an integral part of a piece of equipment or outboard and cable connected. For the type of trouble shooting to be described only the power supply will be considered. It will make little difference if it is integral or not. There will be variations to the typical power supplies in **Fig. 1**. The precautions, notes and sequence will apply to almost any power supply.

An excellent tool for checking for intermittents, broken wires and general probing can be made from a piece of ¼" plastic rod about 8" long. Sharpen one end with a pencil sharpener.

If the power supply is an ac-dc (transformerless) type use an isolation transformer to reduce the risk of serious shock. Any time a power supply is worked on, the filter capacitors should be discharged. Any time the power is turned on then off the capacitors should be discharged. Don't trust your life to a bleeder resistor. Remove any rings, this can save you a badly burned finger. Keep the bench clean and organized. A pencil and note pad are necessary on any repair bench. Keep notes of any wires disconnected and any components removed. The pad is also handy for noting voltages, resistances and etc.

Low voltage diodes can be tested by reading forward and reverse resistance. This test cannot always be used on high voltage diodes as the internal bias voltage of some diodes exceed the test voltage of the ohmeter and the diode will appear open when it is actually ok.

The only test equipment required is a vom and two sets of test leads. One set has insulated alligator clips. The other set has needle point tips. The needle point tips are better than the duller type as the points will pierce any resin flux or other material that could prevent an accurate reading. This is particularly important when working on surplus equipment that has been treated with moisture-fungus proofing.

The more elaborate test equipment will speed and simplify trouble shooting but you must understand the equipment to properly interpret the readings. As an example, an open secondary winding on a transformer can have enough inductance to give nearly a full voltage reading with a vtvm. A vom will load the open winding enough to clearly show it open.

The first step in any trouble shooting should be a good visual inspection.

The following key is designed to help you follow a logical sequence rather than take random tests and hope that you will luck onto the defective part. The key is based on the assumption that a symptom will indicate the failure of certain parts. As an example, if we have a defective power supply and turn it on and the pilot lamp lights it will be a waste of time to check the fuse but we might well check the rectifier tube or diodes. As you follow the key you will note that various symptoms will indicate checks until we have checked every part of the power supply right down to wires, sockets and plugs.

When using the key with a power supply that is not exactly the same as the schematic in Fig. 1, a quick comparison to your schematic will show the steps to follow. If your supply does not have a fuse just pass over the fuse check steps and continue on. If your supply has a three section filter capacitor and two chokes or resistors, make the additional checks when you come to the steps for checking these components in the key. Singular and plural on all components are interchangeable (where the key has diodes, diode will apply and so on). It makes no difference whether the pilot lamp is in the secondary as shown or in the primary circuit. The same steps and checks will apply to a half wave power supply. The key can be used for many low voltage supplies for transistor circuits.

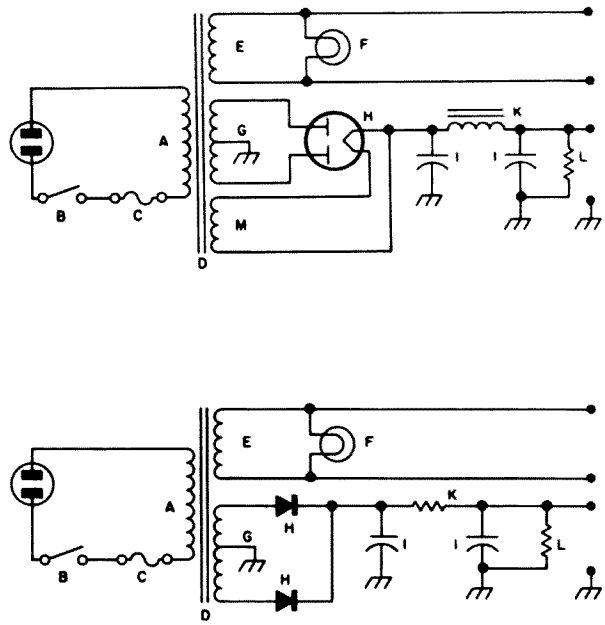

Fig. 1. These are typical power supplies used in Novice gear and were used for making the trouble shooting key. Parts identification: A—Primary winding; B—Power switch; C—Fuse; D—Power transformer; E—Filament winding; F—Pilot lamp; G—Secondary winding; H—Rectifier tube; H—Diode; I—Filter capacitors; K—Choke-coil type; L—Bleeder resistor; M—Rectifier tube winding.

Some of the checks may appear long and cumbersome. The filter capacitor checks are an example. Frankly, it is difficult to check capacitors with a vom. The capacitors are expensive and difficult to replace, so it is worth spending a little more time to be *sure* they are defective. We could reduce steps 15 and 19 to 'Test filter capacitors. Replace if defective.' If you do not have a capacitor tester the key would be of no value to you. Every Novice has, or should have, a vom.

Experienced repairmen use a mental key. This is why the TV repairman asks you, "what does it do?" He wants symptoms so he can use his mental key. As you gain experience in trouble shooting you will develop a mental key. If your key is good enough and generously cross-referenced you will be able to repair the 'tough ones'.

To use the key for trouble shooting determine the primary symptom. If the power supply has more than one symptom you might have to go through the key for each symptom to locate all the defects. The key will indicate the repair for each symptom. The symptom will have a number for a check of a suspected component or components. If the component is defective the key will indicate the repair. If the component is ok the key will indicate the next check to make to locate the defective part.

Key to Power Supply Trouble Shooting

Power supply works – but
Hum is present. Go to 15
Power supply overheats
A. Power supply is overloaded. remove load. If power supply is now ok go to 21
B. Overheating is still present with no load. Go to 20
Power supply does not work – pilot lamp is known to be good Fuse blows. Go to 20
Rectifier tube or diodes are known to be good. Go to 1
Rectifier tube or diodes are not known to be good. If check 2 is ok go to 17
1. The power supply is turned on and the pilot lamp does not light. Go to 3
2. The power supply is turned on the the pilot lamp lights. Go to 10
3. Check outlet to be sure power is available. If no power, check house circuit. Power available. Go to 4

4. Check fuse. Do not depend on visual inspection. Use an ohmeter. If fuse is blown replace. If fuse blows again go to 20. If fuse is ok go to 5

5. Unplug power supply and using alligator clips connect ohmeter to power plug terminals. If ohmeter reads open go to 6. If ohmeter shows continuity go to 10. Be careful here because we may have an intermittent component.

6. Flex power cord at plug and where wire enters chassis. Watch for meter fluctuation indicating intermittent. If cord is intermit, replace it. If circuit is still open go to 7

7. Tap fuse holder. Watch for intermittent. If present, clean or replace fuse holder. If circuit is still open go to 8

8. Wiggle handle or knob on power switch. If intermit. clean or replace switch. If circuit still open go to 9

9. Check each component individually including transformer primary for continuity. Replace any open component.

This completes primary circuit testing. All defects in this circuit should now be repaired.

10. Check transformer filament winding for continuity. If open, replace transformer. If pilot lamp is in primary circuit check transformer primary. If open replace transformer. Be sure to remove any parallel load when checking transformer windings. If ok go to 11

11. Discharge filter capacitors. Go to 12

12. Check all connections for loose or broken wires. Press against wires with plastic probe for check for breaks. Replace any broken wires. If ok go to 13

13. Check any transformer windings not previously checked for continuity. See 10 for procedure. If any windings are open replace the transformer. If ok go to 14

14. Check filter choke or resistor for continuity. If open replace. If ok go to 15

15. A rough check of filter capacitors can be made by using an ohmeter. – to chassis (gnd). + to capacitor terminal (reverse for bias circuits). The ohmeter should show low resistance then slowly increase. If the meter stays on low or high ohms the filter capacitor is probably defective. If defective replace or follow through to 19 for confirming check. If ok go to 16

16. Check the bleeder resistor. It is just a convenient time to do it. Go to 17

This concludes ohmeter trouble shooting. We must now use power on testing to

SSTV RECEIVE AND SEND QSLS OVER THE AIR

'73' DOES IT AGAIN. We were the first to publish a Repeater Handbook. And now we're offering you the first complete book on Slow Scan Television, the coming thing in Amateur Radio.

This book, written by Don C. Miller W9NTP and Ralph Taggart WB8DQT, tells you everything you need to know in order to build your own station so that your face and ham shack can be seen all over the world. It also has many accessories that you build so that your station is better than anyone else's.

ORDER NOW. Only $4.95 for the softbound edition, or $6.95 for the hardbound edition.

BE THE FIRST PERSON ON YOUR BLOCK TO HAVE YOUR PICTURE TRANSMITTED TO AFRICA.

Send to: 73 Magazine
Peterborough NH 03458

☐ Send me___softbound editions of SSTV as soon as they're off the press.
I enclose $4.95 for each one.
☐ Send me hardbound editions of SSTV as soon as they're off the press.
I enclose $6.95 for each one.

complete the trouble shooting. Observe all precautions discussed at beginning of article.

17. Check transformer secondary winding at tube plate pins or diode anodes for proper ac voltage. If low replace transformer. If ok go to 18

18. Check cathode of tube or diodes. Low or no dc voltage, replace tube or diodes. Diodes should be checked individually as only one may be defective. If ok go to 19

19. The filter capacitors can be checked under actual operating voltage. Remove all load from the power supply. The bleeder resistor can be left in if you determine the current flowing through it by ohms law. unhook the wire going from the rectifier to the filter components. Use the insulated alligator clips and MA meter. Connect – to filter circuit, + to the rectifier (reverse for bias circuits). Turn the power supply on. for the average power supply the capacitor leakage should not exceed 5-7 mA. If the bleeder resistor has been left in be sure to subtract the current going through it. If the filter circuit uses separate capacitors and the leakage is high check the capacitors individually as only one may be defective. The no load voltage of the power supply will be higher than the operating voltage but this is good for testing the filter capacitors. If there is no leakage through the capacitors and the resistance stayed high in 15 the capacitor is probably open or reduced capacity and should be replaced. The presence of hum confirms this.

This concludes the power-on trouble shooting.

20. Inspect components for evidence of overheating. Use the ohmeter to check for shorts. Inspect tube sockets, cable plugs and sockets for cracks and 'burn paths' where it could have arced over. Refer to 15 when checking filter circuits for shorts.

A faulty transformer will not always show a short to gnd (chassis). Remove all load from the secondary windings. if the transformer still overheats or smokes it is defective.

21. A fault in the equipment is overloading the power supply and causing it to overheat. Repair defective equipment.

This completes the trouble shooting key. If you have followed through the steps carefully the power supply should be repaired. There will be times when you will be in the mood to debate the following statement; when *everything* is ok the equipment *will* work. Happy trouble shooting.

IMPROVED LOW-COST CD IGNITION

Judging from various construction articles written in recent years, solid-state ignition systems are going through a design improvement stage which bodes well for their final acceptance in the automotive field. Single-transistor, special-coil and multiple-transistor, standard-coil circuits have been around for about a decade, chalking up performance records ranging from good to miserable, with the latter heavily outweighing the former. For example, in my case, a 2N1167A transistor and special 400:1 coil was used for about 3 years with coil failure ending a frustrating series of ignition malfunctions due to point contamination and transistor characteristic change.

A well known automotive parts supplier in Chicago a few years back was vending many brands of transistor ignition systems with glowing praise of its "electronic promise." Today his catalog lists only a couple of high-priced reliable units and it is unlikely that this is due to a saturated market! Information gathered from individual users and garage repairmen point up

Parts List

C1 – .1,100V
C2 – 1.0 μF, 600V oil paper
C3 – .01
C4 – .01, I kV

Q4, Q5 – 2N3055
SCR1 – Small 100.V sen. gate like C106F2
SCR2 – 500.V, 20.A
F1 – 4.A
Q4, Q5 heatsink – Birtcher #4AL-6-0-0
Q3 heatsink – Fuse clip chassis 4x6x2 w/bottom cover
T1 – Core = Ferrox cube #K3-005-01-3E
Wire = 55' #26 Formvar, 4' Ω14 Formvar
Ins. tape Epoxy

Fig. 1. Schematic diagram of the improved low-cost CD ignition.

the basic fact that performance has been less dependable than the simple Kettering system. Besides, if it's more costly, why bother? A set of points and plugs every 10,000 miles is not too great a price to pay for dependability.

However, the search for improvement has continued and now a relative newcomer is in the spotlight, CD ignition. In spite of its greater complexity, capacitor discharge ignition offers much in the way of improved all-weather starting and considerable freedom from point problems. In addition, so-called "breakerless ignition" is more easily implemented with a CD circuit and indeed manufactured systems may be purchased; but for now they are too expensive for the average motorist..

This paper details some interesting results of experiments aimed at improved reliability of a CD system over a wide range of temperature, battery voltage, and ignition point resistance. These very important factors have been lightly regarded or ignored altogether by some designers. Circuitry for the unit shown in Fig. 1 has been simplified consistent with optimum performance and borrows some ideas found in two recent reports. [1,2]

Three objectives, listed in the order of their importance, were borne in mind during development and test: dependability, performance, and cost. Concerning the first, worst-case design limits for temperature, battery voltage, and point resistance were set at −40 to +85°C (still-air ambient), 6–16V, and 20 kΩ, respectively. This required silicon devices throughout, operated well below maximum ratings. All circuit elements are soldered in place – no

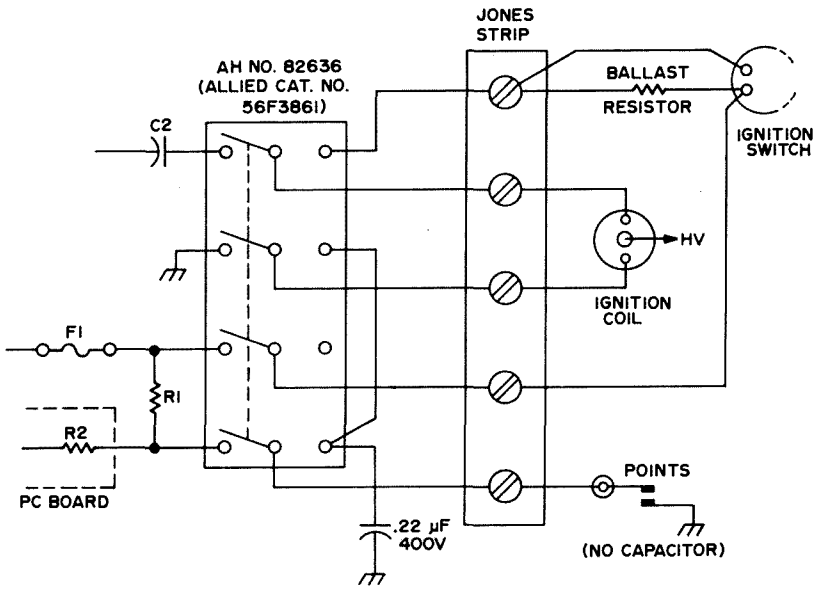

Fig. 2. CD/Normal via 4 PDT switch.

sockets allowed.

To simulate cold weather starting, all parts were cooled to −40°C in a large Dewar flask, point resistance increased by a 22 kΩ resistor and with 6V input, a 1.5 cm spark in air could be obtained, about 18 kV. At the other extreme, full spark energy of about 35 kV was available at 400 pps, 85°C at any voltage between 8 and 16V.

CD ignition requires a source of high voltage dc and this is ordinarily supplied by a dc/dc converter. Much of the cost is right here, in switching transistors and transformer. After experimenting for many weeks with overheated filament transformers pressed into converter service for which they were not designed, great elation was felt in reading the Morris-Morton article with its complete transformer construction plans. A toroid core was quickly obtained and wound to specs. Although lower cost switching transistors were used, performance was exactly as described and a major bottleneck resolved.

Circuit design followed transmitter practice, working from the output stage towards the input. A 1μF capacitor charged to about 350V and discharging into the primary of a regular 12V ignition coil via an SCR was chosen as the starting point. It was soon discovered that inexpensive SCRs were lacking in gate sensitivity and triggering by a UJT was marginal, especially at −40°C. A trigger diode in a standard

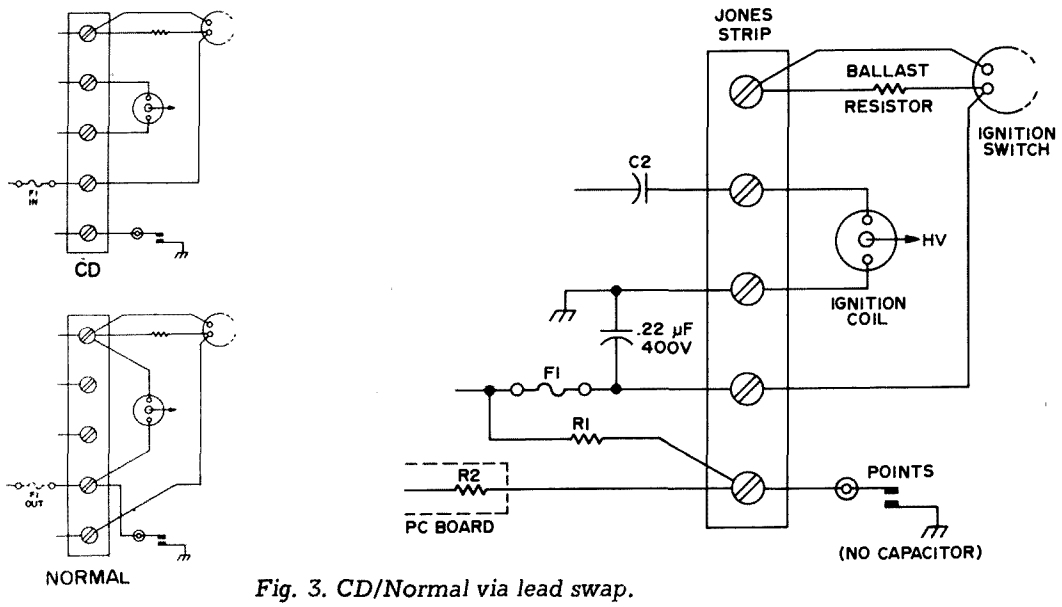

Fig. 3. CD/Normal via lead swap.

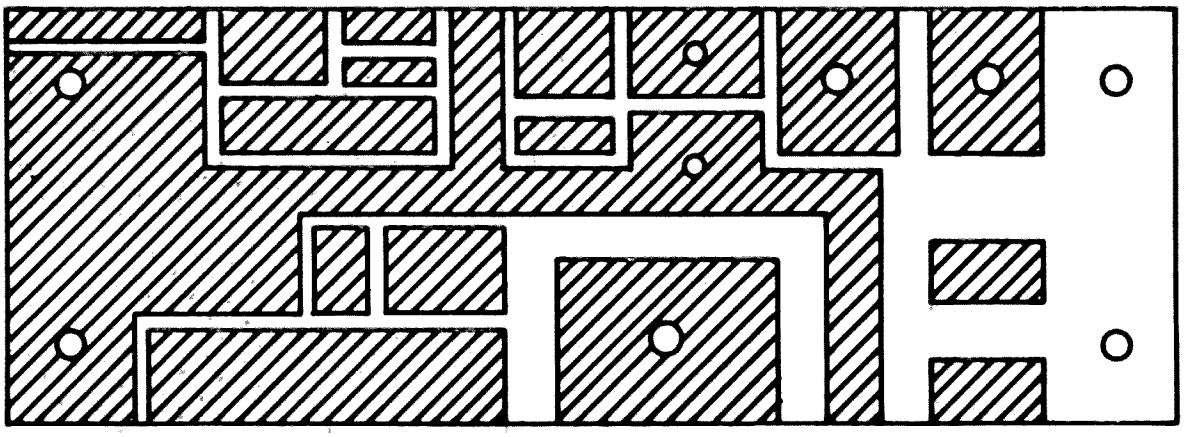

Fig. 4. Actual-size PC layout of board A.

circuit worked fine however, and was incorporated. Its RC time constant takes care of point bounce mentioned in previous papers. No-load B+ of 650V inadvertently applied to a 500V SCR was destructive and after the tears had dried, feedback regulation of the high voltage was added.

An SCR latch connected across the output SCR gate assures only one correctly timed ignition spark for each point opening. Point resistance tolerance and latch reset is controlled by a two-stage saturating switch which has outperformed all other circuits tried. It consists of an NPN switching transistor that can pull the SCR anode down to 0.2V at −40°C (worst case), causing positive reset. Signal inversion, current gain, and dc level shifting is provided by a PNP input transistor. Rate of point opening and closure, ranging from very slow during starting in subzero weather to 400 Hz for a V-8 at 60 mph does not and cannot upset proper operation.

Speaking of breaker points, it seems that oil fumes leaking past the distributor shaft upper bearing, creepage of cam lubricant, ozone inside the cap, and just simple oxidation of tungsten surfaces singly or collectively brings on increasing electrical resistance that can cause malfunction in an electronic system. Without R1, this circuit failed at 920 miles after initial installation, using brand new points running essentially "dry circuit." A single swipe across the points with a book match cover got us going again immediately, but it was a loss of 100% reliability. Current bleed via R1 of fractional ampere has proved to be a reliable solution during 22,000 miles of failure-free driving to date. Apparently a tiny arc at point opening time vaporizes whatever contaminant may be present, preventing buildup. The higher energy level in the high tension circuit requires clean, film-free surfaces on rotor and inner cap which is at it should be anyway.

There are some circuit details that, when properly dealt with, will insure utmost dependability. (1) Q1 must have low emitter-collector leakage when heated to 100°C; (2) SCR 1 should fire with 3 mA or less gate current and stay latched up when very cold, with 6V applied to R4; (3) Q3 should have a beta of at least 40 and be provided with a small heatsink, as it must dissipate 400 mW; (4) Q4 and Q5 must have a moderate-size heatsink as they heat to 100°C when all limits are high; (5) surplus high-power SCRs are inexpensive and a 20A unit will loaf along without heatsinking; (6) D3 and D5 protect Q3 from transient pulses normally present on the B+ line and D3 provides additional safety for SCR 2 by way of brute-force limiting via the zeners if Q3 should fail; (7) power zeners are also an excellent buy—use 'em; (8) procure a quality capacitor for C3—MIL-type oil paper in metal cans often

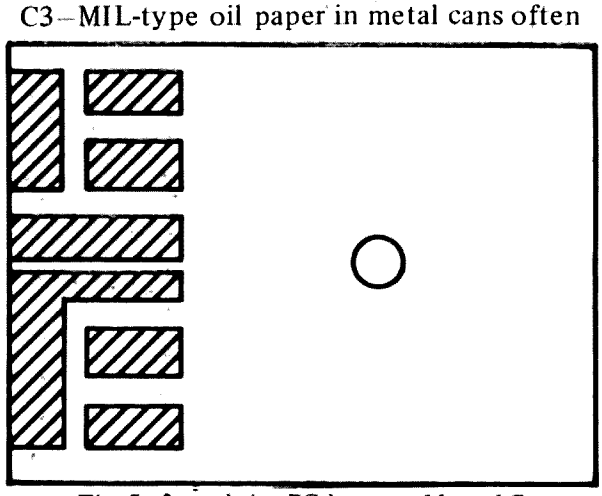

Fig. 5. Actual-size PC layout of board B.

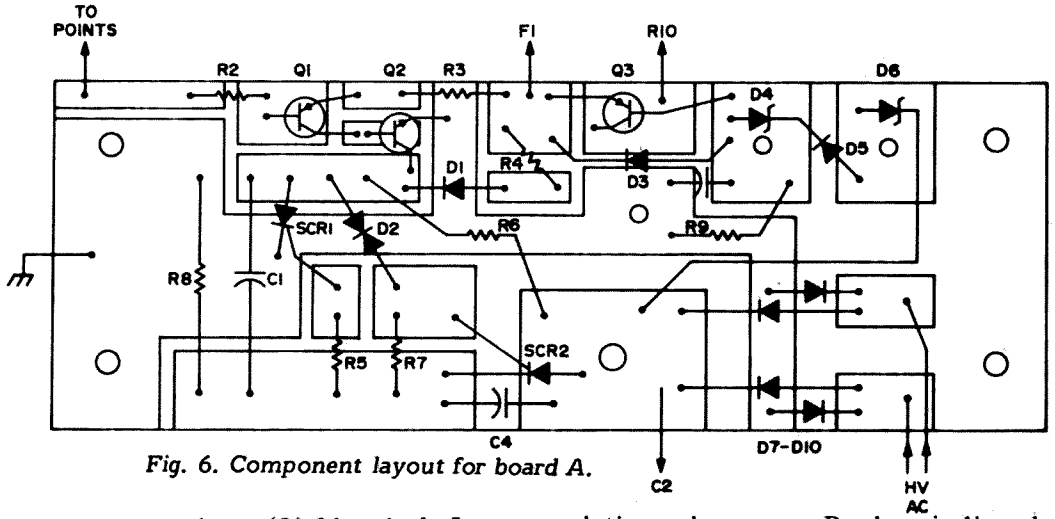

Fig. 6. Component layout for board A.

go for a quarter apiece; (9) Murphy's Law being what it is, switch-back to standard ignition can be provided for either by a four-pole double-throw toggle switch or rearrangement of leads on the Jones strip with quick-disconnect terminals.

Make the PC boards from 1/16 in. single-clad stock. They are designed for face mounting of components, which saves lots of drilling. Wire up the large one, deleting R1 for now. Mount Q4 and Q5 on their heatsink using 6 in. long coded leads. If reference 1 is not available, wind T1 in the following manner. Obtain the specified core and apply an even layer of thin insulating tape. Make a bobbin of strong flat material such as plastic or a tongue depressor and notch the ends to a 6 in. inner spacing. Once around is about a foot, so put on 50 ft of #26 Formvar insulated copper wire. Wind all of this wire on the core in 6 bank-winding sections of 45/50 turns per section and scramble wind where necessary to even the layers. Leave a 1/8 in. gap between start and finish for insulating clearance. Bank winding helps to minimize potential differences along the winding. Cover with a smooth layer of insulting tape. Then put on 20 turns of 14-gage insulated copper wire (4 ft) evenly spaced around the core, with ends opposite the first layer leads. Centertap this winding. Finally put on 10 turns of 26-gage wire, its centertap adjacent to the other, interleaving the small wire between the heavy wire.

Connect the transformer per schematic, then breadboard the entire circuitry for initial testing, using a spare or borrowed ignition coil. Provide a ½ in. sparkgap. Wire a 22 kΩ resistor between R2 and "points" (touch resistor lead to ground). Apply input voltage and watch the sparks fly!

A median value for R10 is about 220Ω. It can be optimized if test equipment is available. The dc/dc converter efficiency is maximized by use of the highest resistance value at R10 causing a 2.8A current drain at +14V when the system is delivering 400 pps into a 1/8 in. sparkgap. Too low a

value will cause excessive heating of Q4, Q5 and a tendency to "squeege"; too high a value will reduce B+ so that high-speed performance is poor. 180–270Ω are ballpark limits.

Mount the transformer on its PC board after completion of tests. Adjust lead dress, then coat generously with insulating epoxy, securing T1 in place at the same time. Leave a center opening for passage of a mounting bolt. After the epoxy has hardened, solder each lead to a PC terminal according to the drawing.

Packaging is the next order of business before actual installation and roadtesting gets under way. The photos show one arrangement using a 4 by 6 by 2 in. chassis with bottom cover. It is a good idea to make the unit drip-proof by sealing all openings with silicone rubber caulking available at most hardware stores. Centralize the large heatsink so that metal straps across the chassis ends can secure the box in place without interference. Don't forget to install R1.

Underhood installation of the completed unit should be such that radiator fan cooling air or incoming air in the case of rear engined vehicles can flow across the heatsink and there is protection from rain, snow, and puddle splashing. Don't overlook inside mounting. Although the air is relatively calm, temperature extremes are less and exposure to weather is avoided. Annoying whine at 1 or 2 kHz of the usual converter is nonexistent in this one which oscillates at 10 kHz. Position so that switch-back to normal is easy, in case of difficulty.

Electrical connection requires tapping into the ignition switch circuit ahead of any ballast resistor, disconnecting the points capacitor and possibly adding leads to tie into the distributor and coil. Check out the connection schematic to see how it's done.

This particular circuit lends itself well to "breakerless" ignition experiments, either optical or magnetic. One breadboard test made use of a variation of blocking oscillator, abrupt start-stop control being effected by a small permanent magnet in proximity to the oscillator toroid core. These ac burst signals drove Q1, eliminating all contact problems.

Acknowledgement is made for the many helpful suggestions and enthusiastic encouragement of my friend and colleague, Mr. Dario Dorigo. His CD in a Corvair is performing in excellent fashion.

LIGHTNING

Nikola Tesla watched, elated, as the needle on the ammeter pinned. The room was filled with a roaring, crackling noise and the smell of ozone permeated the air. The scientist walked outside. High atop his laboratory, a metallic globe was alive with a hissing blue cornona. While he watched, fascinated, a bolt of man-made lightning leaped from the globe to the ground. Seconds later, another bolt leaped out a little farther than the first; then another struck farther still. Tesla's machine even seemed to be drawing lightning from the air around it.

Suddenly the noise stopped. Silence closed in like a cloak as the machine went dead. Tesla rushed back into his lab. His machine was intact, but there was no power. The experiment had been terminated by a local power failure. Furiously he telephoned the power station demanding an explanation.

"You're not the only one who wants an explanation," the voice on the other end of the line retorted, "You've just melted the windings in three of our generators. It'll be a cold day in hell before we send any more power out to you!"

It is doubtful that even this brilliant scientist fully realized the awesome magnitude of power involved when he tried to produce lightning, for although it is usually dissipated with comparatively little damage, a single stroke of lightning can contain as much electrical energy as today's average family consumes in a week. A storm of moderate intensity can produce many times the energy of a nuclear bomb.

The actual amount of power in a lightning stroke is the subject of considerable disagreement in the engineering world. Some authorities say that the voltage represented by a lightning stroke is in the neighborhood of thirty million volts. Others claim the voltage can be as high as 900 thousand volts per foot. At that rate, the voltage of a stroke, which can be as much as ten miles long, would reach astronomical magnitudes. The current, on the other hand, is generally agreed by the various authorities to range from four thousand to a quarter million amperes. The duration has been measured at 5 to 50 microseconds.

The electrical charges that produce lightning are thought to be produced by friction between rapidly moving raindrops and the surrounding air. Thunderheads are known to contain vertically moving air columns which reach velocities in excess of 100 miles per hour. Raindrops and ice particles, moved about by these currents, develop electrical charges. The vertical movement accumulates these charges much in the same manner as the vertically moving belt in a Van de Graaff generator.

The turbulence within a thunderhead develops a strong negative charge in that region of the cloud where the temperature is between 0° and 32°F. A positively charged zone develops in the upper portion of the cloud, and the lower portion of the cloud contains both positively and negatively charged zones. From this it can be easily understood why 65% of all the discharges are within a cloud or between clouds.

Lightning strokes, either within or between clouds, or from a cloud to the ground, occur when the voltage between charges of opposite polarity exceeds the breakdown potential of the intervening air gap. This breakdown is of a different nature than the breakdown of a small air gap. There appears

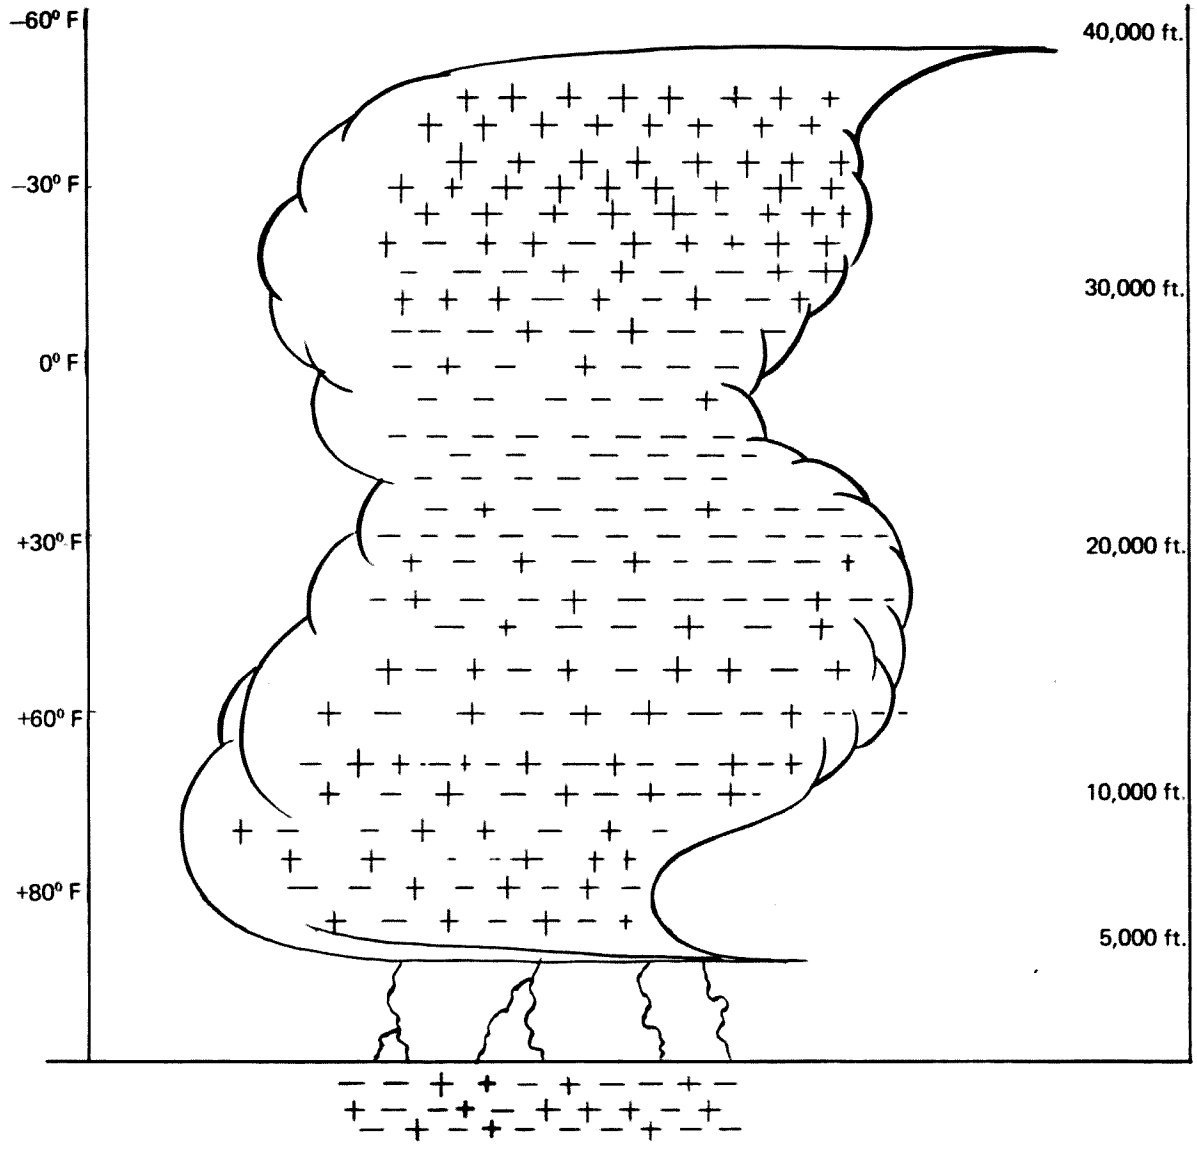

Fig. 1 . A thunderhead is a towering cylindrical cloud, often extending as high as 40,000 feet. Negative charges generally accumulate in the region of 30 to 0°F. Positive charges accumulate in the upper portion. Both positive and negative charges occur in the lower portion. The characteristic anvil top is caused by upper atmospheric winds.

to exist a potential, the exact magnitude of which is yet to be determined, beyond which air breaks down a little at a time.

As charges accumulate in the lower portion of a thunderhead, equal and opposite charges are produced by electrostatic attraction in the ground and all grounded objects below. As the potential passes the breakdown level, "leader strokes" begin probing their way toward the opposite charge. Usually the leaders start from the cloud, but sometimes from the ground. Advancing 50 to 60 yards at a time, and pausing about 100 microseconds between steps, the leader works its way toward the opposite charge. Then current flows, a small stroke dissipating as much as five kilowatt hours, and a large stroke, many times more.

A lightning discharge, like any electric current, follows the path of least resistance which is almost never a straight line. The potential gradient from a cloud to the ground is constantly being distorted by the turbulence of the atmosphere On the ground, moisture, temperature, and the varying quality of the ground itself play important roles in determining the path of a stroke. With all these variables, lightning has been observed to do some pretty strange things. A neighbor of mine had her house struck. The bolt travelled down a drainpipe, followed the electrical wiring across the

cellar into the back shed, then jumped to a sink, scaring the tar out of her son who was repairing his bicycle in the shed.

Some of the phenomena manifested by lightning are so weird that it becomes hard to separate fact from fiction. For instance, ball lightning was long thought to be an old wives' tale. Too many credible observations by competent personnel have been reported, however, to pass it off as a myth. Present theories consider the phenomenon to consist of a small, heavily charged mass of ionized air that becomes separated from the path of a stroke and then drifts along with natural air currents until it either dissipates or finds a ground path where it discharges, sometimes with explosive violence. Sheet lightning is thought by some to be merely reflections of lightning discharges in a faraway cloud. Others think it is the instantaneous discharge of a large area of atmosphere, spreading the energy that would otherwise be discharged in a stroke over a wide area – a sort of high-speed Aurora Borealis.

People have gone to great lengths over the years to protect themselves from lightning, ranging from charms and prayers to more scientifically sound methods. When Mr. Franklin invented the lightning rod, all sorts of applications were tried. An early drawing depicts an umbrella with a lightning rod on top and a conductor trailing off along the ground. Good thinking, but a very dangerous device. Lightning rods today are confined to the tops of buildings.

Modern-day lightning rods are generally pointed, not so much to make them more likely to be hit as to prevent the buildup of charges that would lead to a stroke. It is generally known among those who work with high potentials that a point encourages corona discharge. Working on that principle, the point on a lightning rod constantly bleeds off accumulating charges thus pre venting their building up to a dangerous level.

In the communications field, lightning protection varies depending not only on the nature of service but on the geographical location as well. This is because the frequency and severity of thunderstorms varies throughout the continent. Equipment that is protected sufficiently on the west coast would go up like a Roman candle in central Kansas or on the Florida peninsula. In the latter two areas, electricians do as much business repairing lightning damage as they do putting in new installations. The Great Lakes region has 50% more thunderstorm activity than the New England coast. By contrast, southern Alaska has perhaps only

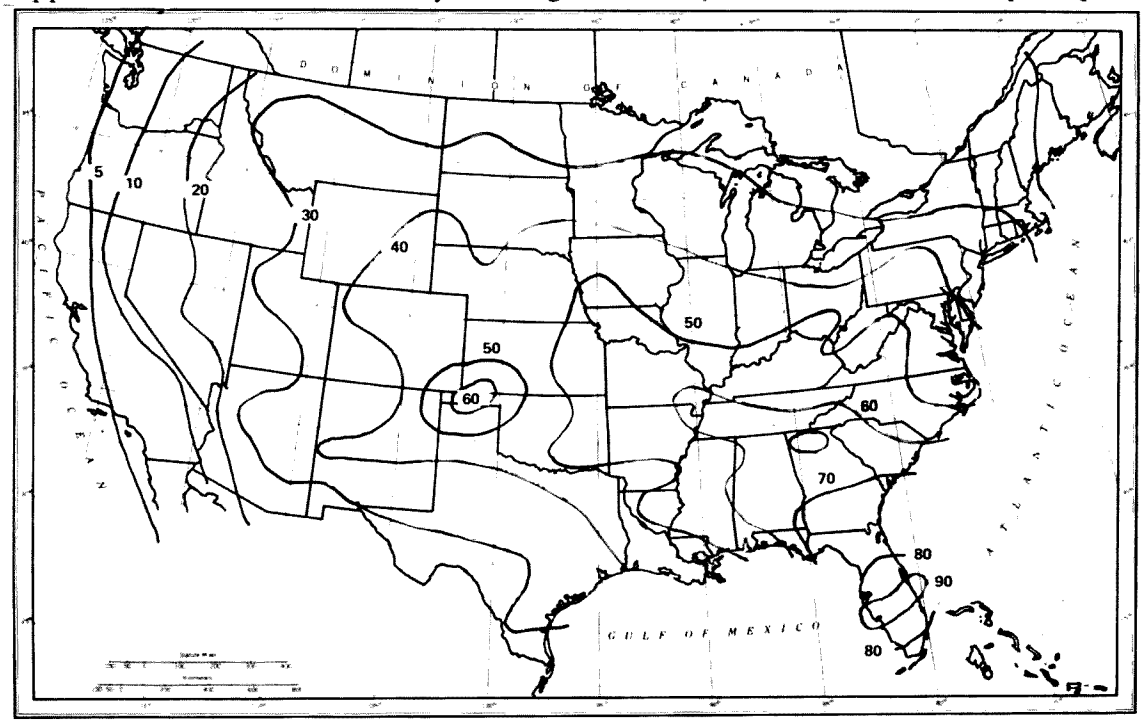

Fig. 2. Average number of days of thunderstorm activity per year in continental United States.

one day of thunderstorm activity in two years.

Protection requirements further depend on the amount of exposed wire and on the conductivity of the ground. It is much easier to protect equipment situated in a salt water marsh than in dry, sandy soil.

It should be realized that virtually nothing can protect an antenna or signal wire from a direct stroke. Considering the tremendous magnitude of current involved, it is easy to understand that even a very heavy ground conductor might be vaporized. However, proper protective equipment pays for itself, protecting equipment against a little-publicized phenomenom known as a ground surge.

In order to better understand a ground surge, picture for the moment the plates of a charged capacitor. When a conductor is connected between the plates to discharge the capacitor, current flows through the conductor from plate to plate, and *from all points on the individual plates to the conductor*. Comparing an electric charge in a cloud and the ground below it to the places of a capacitor, and imagining the path of a lightning discharge as the shorting conductor, it is easy to see that each time lightning strikes, current flows through the path of the stroke from the ground to the cloud; current also flows through the ground from all surrounding points to the point where lightning strikes.

If lightning struck a point several hundred yards from an antenna tower, current would flow down out of the tower and through the ground to the point where the stroke occurred. The magnitude of these surges can be as high as ten percent of the current in the lightning stoke itself – as much as several thousand amperes. If the equipment in your shack were grounded at more than one point, a ground surge might find an easier path through the interconnecting wires than through the ground. In that case, goodbye equipment. This one hideous thought clearly illustrates the reason for one and *only* one ground point in a well-protected shack.

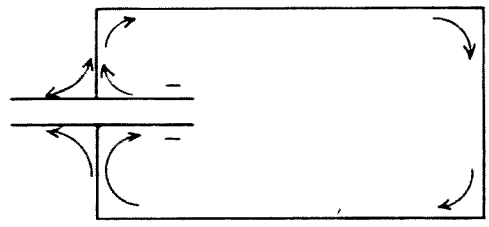

Fig. 3A. When a capacitor is discharged, current not only flows through the shorting path but through all parts of the plates as well.

Where remote control lines or other types of signal wires run long distances above ground, ground surges from lightning are a major problem. The railroads, using unshielded signal lines running for miles at a stretch, often go to great extremes to protect their delicate and costly signal equipment. Each line has a heavy-duty lightning arrester connected to ground at the point where it enters a wayside housing. Electronic devices such as carrier-current transmitters and receivers are further protected by high-speed gas discharge tubes on each terminal.

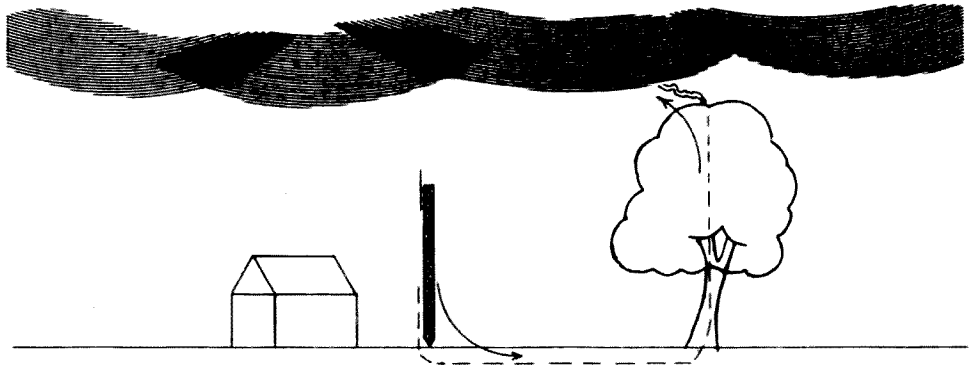

Fig. 3B. Picturing the sky as a plate of a charged capacitor and the ground as the opposite plate, a lightning stroke causes current surges to flow down out of nearby grounded objects, through the ground, and along the path of the stroke to the sky.

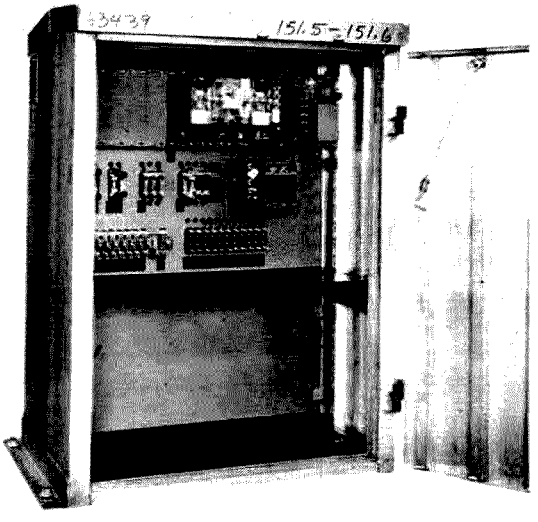

Every ground terminal within the housing, as well as a connection to the housing itself, is brought to one common ground point called the "prime ground terminal" which is connected to earth ground through the lowest resistance path possible. Railway signalmen have told of standing inside a wayside housing during a storm and seeing the arresters constantly flashing like a small fireworks display. A severe surge will cause a railroad arrester to blow off its glass covering with a report like a gunshot.

Although telephone lines often run long distances above ground, many types of cable are shielded, and surges occur mainly in the shield where they harmlessly bleed off to ground.

In the home, the telephone line is connected to ground through two carbon fuses of carefully calculated resistance. One carbon fuse connects each side of the line to ground, thereby holding each side of the line at an equal potential above ground, thus zero volts with respect to one another so far as alien power surges are concerned.

At the exchange each incoming conductor is connected to ground through a carbon fuse and all the ground connections made through one common terminal.

Commercial broadcasting stations, as a general rule, use relatively crude lightning protection methods. A piece of heavy bar

A typical wayside case for railway signal equipment. The lightning arresters are in the bottom row at the left of the case. (Photo courtesy General Railway Signal Company)

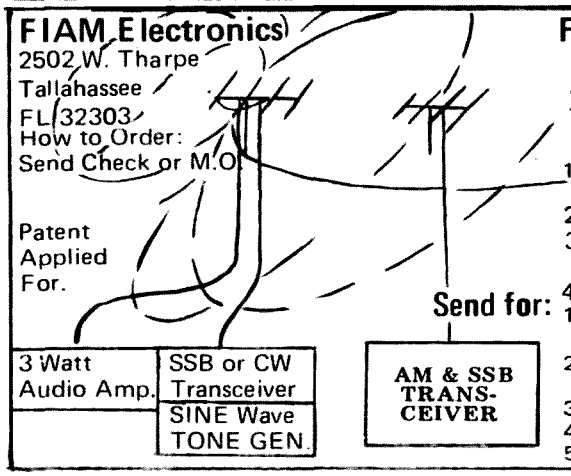
Lightning arrester at the base of a commercial broadcasting tower (WADD, Brockport NY).



stock with a ball shape on the end is connected to the base of the tower and positioned in close proximity to a similar piece connected to the ground system. This is generally sufficient, since the transmitting equipment is quite rugged and of low impedance. About the worst that generally happens is that a breaker opens, putting the station off the air until an engineer resets it. There have been occasional colorful results however. The engineer of one local station told of a strike following the transmission line into the building and making a spectacular display as it zipped around the baseboards, finally grounding out via several electric outlets.

Lightning protection, then, depends upon many variables. Factors such as the amount of thunderstorm activity, the amount of exposed line, the equipment to be protected, etc. To even begin to describe the various techniques and the reasons for them would take a book of considerable size. Perhaps the main determining factors are the possible consequences of loss, and the economic status of the owner of the protected equipment.

73 REVIEWS THE REGENCY AR-2 2-METER FM AMPLIFIER

If the growing number of manufacturers of power amplifiers for 2 meters, only two (as of this writing) are very conservatively rated on the input and output ratings of their amplifiers. One is on the west coast and the other is Regency in Indianapolis, Indiana. Regency again has followed the tradition started in the HR-2/2A transceivers of being very conservative on power ratings. They rated the HR-2 at 10 watts. It put out at least 12. They rated the HR-2A at 15 watts. It puts out almost 18.

The new AR-2 is made in a matching size and style to be a companion to the HR-2/2A transceiver. When you pick it up, you would think it was made of lead. It's hefty, yes, but not from lead: copper is the name of the heat sink material that is used. The AR-2 is literally an amplifier built on, or almost in, a huge copper heat sink. Does it get hot while transmitting? Not with PTT operation. With 10 watts input, Regency rates the amplifier at 38 watts output – ours put out 44. With 15 watts input, the AR-2 put out 58 watts, and with 17 watts input to it, out came a full 67 watts. That kind of power output coupled to your 3 dB gain antenna will let you talk to the machine on the mountain just about as far as you can hear it. And would you believe that at almost 60 watts output (key down for an hour) this AR-2 barely gets above room temperature – that big heat sink really does its job. Even the collector output tank circuit is constructed of heavy silver-plated copper to better withstand the large rf circulating currents that are found in solid state amplifiers at these frequencies and power levels. The AR-2 uses 2 transistors in a Class C push-pull configuration. The transistors used are of the balanced emitter type with the new wide leads to provide low inductance lead runs. The AR-2 amplifier runs between 60 to 70% overall efficiency.

Installing the AR-2 is a oreeze. Just connect 12V to it and plug in your antenna to the amplifier. Placing a short coax jumper between the transceiver and the amplifier completes the job. To tune the amplifier input up (to compensate for the input feedline lengths) it's best to have a Bird model 43 Thruline® or Model 4352 Ham-mate® watt meter. This is placed between the antenna lead and the AR-2. With the amplifier out of its case, key the transceiver and tune everything for maximum rf output. The amplifier switches itself in automatically when it senses watt or

more at its input. If you want to run barefoot for short, direct hauls, just turn the amplifier power switch to the off position. When the amplifier power switch is in the on position, a front panel red light comes on each time the amplifier is keyed.

Maybe quadrupling your output power won't quite double your range, but with the additional power your transmit range doesn't run out before your receive range does. All those marginal areas where you were noisy into the repeater disappear and now you are full quieting. If you are out in the boondocks or hilly areas like southern New Hampshire, that extra power really does make a difference.

For more information on the AR-2 write to *Regency Electronics, Inc., 7900 Pendleton Pike, Indianapolis, Indiana 46226.* The AR-2 amplifier is priced at only $129. When you figure it out, that's only two bucks a watt output and that is cheap. Regency again has turned out a very nice unit at a modest price.

CONTENTS

5 Modern VHF Counter K2OAW
Part 2 of 3. This will be followed by a frequency synthesizer as part of the system.

15 Solid State VHF Amplifier W9ZTK
FM again? Well, actually any VHFer should enjoy building this experimental amplifier. Looks ideal to beef up the new International Signal rigs.

19 The Phased-Lock Loop K4ZFD
Hey, read this and snow everyone on 3999 with your tremendous technical knowledge.The P-L-L is here to stay so you might as well come to terms with it. The terms are easy.

23 VHF Converters W8RHR
Dual gate Mosfets, the best thing since DUZ?

31 Add $15 T-Power WB2BJN
Vibrators are out, right? So here's a replacement to help you get that old kluge FM rig on the air.

33 1296 MHz Mixer WB2YVY
Don't sneer, odds are you'll be looking back on this article in a year or so when you start thinking 1296 seriously.

45 Thick Film R-F Preamplifier K9STH
For any band, really — but great for FMers.

63 The Heath IB-102 Prescaler W4FQM
The 73 Tech Ed checks it out. Likes.

69 The VHF Specialists FM Amplifier K1NUN
Ten in, fifty out for 2m FMers.

71 Meteor Shower DXing W5KHT
Real easy way to work 50 states on 2 meters. Haw!

83 Tone Decoder and Carrier Relay Circuits K2OAW
Using the 741 op amp. Face it fellows, the 6SN7GT is no longer state-of-the-art and you might just as well start reading these op amp and phased lock loop articles without gnashing your teeth.

89 Flying Spot Scanner for SSTV WB8DQT
Solid state unit, simple, relatively. Are you going slow scan right now or going to wait and miss a lot of fun you could have had?

97 Active Filter Design, Part II K3PUR
Another chapter in the exciting "Filters Can Be Fun" series. Don't miss the madcap ending next month.

73 Magazine is published monthly by 73, Inc., Peterborough, New Hampshire 03458. Subscription rates are $6 for one year in North America and U.S. Zip Code areas overseas. $7 per year elsewhere. Two years $11 in U.S. and $12 overseas. Three years $15, and $16 overseas. Second class postage paid at Peterborough NH and at additional mailing offices. Printed at Menasha, Wisconsin 54952 U.S.A. *Entire contents copyright 1972 by 73 Inc., Peterborough NH 03458.* *Phone: 603-924-3873.* *Don't forget to join Lin and Wayne for the European trip in September (page 60). Make note of the proposed DXpedition to Bajo Nuevo (page 112). Will we see you at Expo in July (page 70)? Will you forget to send in the readers service request (page 128)? And wait until you see the coming Rig of the Month contest starting soon in 73! Heh! Articles needed: IC construction projects, SSTV, RTTY, FM, etc. One last message for this month: 220 MHz, use it or lose it.*

EDITORIAL BY WAYNE GREEN

Ham Jamming

The service nets on 40m have been having troubles with jamming . . . catcalls . . . music . . . the works. Hopefully, all involved will recognize there is much to be said on both sides of this controversy, although the situation may look black to one side and white to the other.

The net ops feel they are spending a lot of their time and money providing a valuable public service and that this should not only be appreciated by other amateurs, but they should get some cooperation, to boot. The nets are, in fact, providing valuable services in many instances and, if all amateurs would cooperate, could be of tremendous value as a public service and as a proof of the value of amateur radio.

On the other side are ops who are indignant that any group has the audacity to "own" a frequency. The frequencies are free and open to anyone and they get madder than hell when a net opens up and demands they move off the net "frequency." Then again, there are also those ops who feel that anything organized should be destroyed. If anyone is doing good or being helpful, they should be stopped. In the past these people have broken the noses off statues, burnt books, shredded paintings and smashed babies in front of their mothers . . . they are still at work, even in the hambands, making life miserable for as many people as possible.

What is the answer? Or better, what are some answers? May I suggest some possible avenues for the service nets. High on the list I would put PR. PR on the air . . . courtesy above and beyond the bounds of reason. PR in the media . . . see that the editors of ham magazines and club bulletins get info on services rendered by the nets. As an editor I can affirm that this PR has been sadly absent in the past. With only a little effort and organization any or all of the nets could have had considerable coverage in 73 . . . and probably the other magazines as well . . . perhaps even with monthly columns. PR is the name of the game.

The recent appeal to the chairman of the FCC for help in fighting the jamming of one of the nets did not seem to fall on receptive ears within the FCC . . . and seemed ill advised to me. One of the basic benefits of the amateur service has been our boasted ability to be self-policing . . . so when we run into a problem we make a big stink and put the pressure on the head of the FCC for help. Nuts.

Is it really impossible for us to be self-policing? Must we turn to the FCC to police our bands and solve our problems .,. . recognizing that there is more than a little possibility that our problems are to some degree self-generated? Are the net members really impotent to help themselves? Have they no possible way to organize a system for locating jammers and quieting them? I think all of us recognize that this is ridiculous on the face of it.

If we find that our nets are being jammed we have to do something about it. The techniques for locating a jamming station are not all that difficult for us. Direction finding is simple. Not only is it simple, it is fun. Once the offending amateurs have been located there are several ways of handling the situation. I do not think that brute force should be called for except as a last resort . . . cutting of feedlines, pins in coax, bloody noses should be avoided.

There is no reason why illegal acts should be necessary to stop jamming. The great percentage of jammers will stop their nonsense once they have been uncovered. The few remaining bad guys should listen to reason if visited by a committee.

Isn't that better . . . and more satisfying . . . than asking the FCC field engineers to spend the incredible amounts of time it takes them to chase down our jammers? Let's do it ourselves.

Repeating Non-Amateur Stations

The regs are clear on this. . .it is illegal. Yes, I know that some of the two meter repeaters are set up with tone coding which connects them to the time signals from CHU. I don't see the harm in this. . .and I certainly appreciate the utility of it. I spend a lot of my time within range of a two meter transceiver and a lot of it out of range of a short wave receiver.

By now everyone must be familiar with the time signals from CHU. . .on 3333 and 7335 kHz complete with ticks every second and voice announcements every minute.

Another popular public service that is being toned on by some repeater groups is the Weather Bureau broadcasts on 162.40 or 162.55 MHz, depending on where you are located. There are over 60 of these stations around the country and they play tapes of the weather report continuously. . .and most of them update it every half hour or so.

Perhaps we should give some thought to proposing an official change of the regulations to permit short rebroadcasts of public services such as these.

New 73 Staffer

Keith Lamonica W7DXX has joined the 73 staff in the position of Managing Editor. Keith has been quite active in FM, having set up repeaters recently in Oregon and Tennessee. He is also quite interested in DXing and will be working hard to organize some 73 DXpeditions. Say, would it be possible to have a "DXpedition of the Month?" Let's see, Bajo Nuevo in November – maybe Serrana Bank in December – Cayman Islands in January – Grenada in February – and on around the rarer Caribbean islands. Hmmm?

Keith is hopelessly addicted to amateur radio. In the short while he has been with 73 he has gotten one repeater on the air and is almost up to DXCC from Peterborough. He's got several more repeaters in the works, together with a lot of interesting repeater functions, so the amateurs in northern New England will have some advantages over those elsewhere, being able to down link.

Why the FCC Hassles Hams

A recent rash of harassments of hams by the Michigan FCC Engineer in Charge, who seemed to have nothing better to do with his government financed time than to demand log books from FMers, made me wonder why he wasn't devoting some of his time to trying to clean up the CB problem which is really miserable in his particular area.

A letter from an amateur who works in broadcasting and who has asked not to be identified explains the situation. He talked with a pair of FCC field engineers and they said that they could care less what happens on 2m FM. . .that if anything illegal was going on they depended upon amateurs to take care of it and, at worst, if reported to the FCC, they would look into it. They also do not check CB. They do check the broadcast stations in great detail, running audio proof of performance; they checked

wo-way commercial users for fre-uency and proper operation. But ney just don't check the CB band ecause if they do catch a violator it ist means more work for them. With ie broadcast and business band they re dealing with intelligent and respec-ible people when they issue a cita-on. With CB they are dealing, more ften than not, with idiots. To make ieir job easier they just don't mess ith CBers.

This makes sense, even if it is bviously unfair. Perhaps the FCC eeds a staff of field engineers just to heck up on CBers?

tandard Repeater

Standard Communications has been orking hard to firm up the design on repeater package for a complete two ieter repeater station. In early May iey announced that production had arted on the first run of the units id that the first deliveries were heduled for early July, parts sup-liers willing. The basic units are the tandard model 803 commercial VHF ansceiver boards and the transmitter ins ten watts output. There is a mike ck for a regular Standard micro-hone and a speaker jack for an 8Ω peaker.

The whole package will sell for 595! At that price the number of vo meter repeaters may start zoom-g. That is mighty attractive for a mpletely solid state unit. Many of ie Progress Line repeaters may iange to solid state – it does hold omise of needing a lot less main-nance. It is a bore to get to the top your mountain through six feet of ow to put in a new pair of 6146's hen the old ones go soft.

Will the new repeaters sell? Well, ie day they were announced by andard there were at least three rush ders placed.

ew FM Transmitters

A letter arrived the other day from ternational Signal – the same com-any that makes the fine Clegg equip-ent. It seems they were considering aking some little transmitters avail-ble to the amateur market and won-ered what the reaction to them ould be. The reaction of the others ho received the mailing must have een about like mine . . . I sent in a eck immediately for a bunch of em.

The little rigs arrived in due course d they are fascinating. They are mplete with crystal and micro-hone. All you have to do is connect to an 8-volt battery and antenna id you are on two meter FM – or six ters – or even ten meters. There three different models.

The transmitters are quite well built. They use an 8 MHz crystal oscillator, run the rf through two triplers and a doubler, a buffer and a power amplifier – with an output of 0.1 watt. The mike is a small flat job with high impedance output and feeds into an amplifier, limiter and Darlington amplifier to the phase modulator.

The whole rig is 2½ x 3 x 1 in. and is built on excellent PC board. With that small size you could easily install this in many of the receivers to make a transceiver . . . in a hat for conventions . . . in a little tiny repeater package which would make it possible to have a repeater in your car . . . etc. The mind boggles.

The two meter transmitters will be selling for about $33! Line forms to the right . . . of me.

Equipment for 220 MHz

The Tempo 220 transceiver is scheduled for deliveries starting in July. This $220 AM-FM transceiver should be exceedingly popular. A recent poll in the midwest showed that about 80% of the active two meter group are planning on going on 220 as soon as equipment is generally available.

The Clegg 21 is scheduled to be available about the same time. This unit has some very interesting features, such as using one crystal for both transmit and receive. It will be priced under $300 according to present plans.

The Drake 220 unit will hopefully be arriving from Japan in reasonable quantities this summer and help a lot more fellows get on the air. The price is not firm on this one.

Surplus fans may be interested in the Comco 278 transmitter-receiver on sale by Fair Radio for $40. This is probably an AM job, but certainly can be converted easily for the new FM repeater service. It is tubes, and runs from 6, 12 or 24 volts. It looks like fun. It might be made into a low cost repeater.

Tell Our Advertisers You Saw It in 73

Unused Citizens' Band?

The Electronic Industries Association proposal for taking the amateur 220 band and turning it into a new citizens band is even more curious when you look into the use that has been made of the 460 MHz citizens band. Here the rules are quite similar to those proposed for the desired 220 band, yet activity is negligible in this band. Most of the very few users of the 460 band seem to be businesses which could easily be moved to business bands.

A chap I know has a repeater set up in the 460 band, licensed by his wife. He has the channel virtually to himself, even though he lives in a major city. He says there are a couple of other licensees for the channels he is using, but only one has any activity at all – a police department at a local university.

Perhaps interested amateurs should bring this situation to the attention of the EIA and some of the congressmen that are getting to pressure the FCC to shove through the 220 band steal from amateur radio.

Looking for Work?

If you would rather work for a ham magazine than anything else, you might think about the possibilities of coming to New Hampshire and working for 73. We are growing and expanding and are looking for licensed amateurs to fill several positions. We have a spot opening as an advertising assistant. This would pay on the order of $75 a week or so. We can use some help in the art department with laying out pages and doing finishing paste-up. This starts about the same rate. A good typist for setting our type on the IBM Composer would be worth a bit more as a starter.

The pay is not great, to be sure, but think of the fringe benefits – the gear we get to play with here – the repeaters we can set up – extra good deals on personal equipment – even the possibility of getting to go on a trip now and then.

If you are interested please drop us a line with your resume and tell us about your ham background.

A MODERN VHF FREQUENCY COUNTER

Peter A. Stark K2OAW
196 Forest Drive
Mt. Kisco NY 10549

Part 2 of 3 parts

Two months ago we started describing our frequency counter design, showed how to use it, and gave a complete parts list. This month we will provide the complete logic and schematic diagrams, and describe how it works, and next month we will have the printed circuit board layout, parts layout drawings, and construction and operation information.

Figures 3 through 18 show the diagrams of the various parts of the counter. To see how these parts fit together, refer back to Fig. 2, the block diagram, in last month's article.

0–20 MHz Input Circuit (Fig. 3)

This circuit is one of the most tricky circuits in the counter, since it must convert a variety of input signals, large and small, simple and complex, into digital pulse signals of just the right voltage and speed to operate the counter. This job is considerably simplified by a Schmitt trigger IC, an SN7413N, designed just to interface TTL digital logic to the outside world.

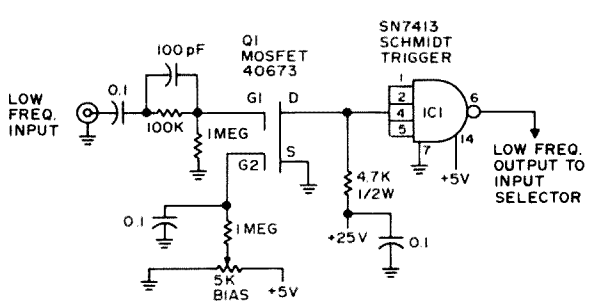

Fig. 3. 0–20 MHz (low frequency) input circuit.

The low frequency input circuit starts off with Q1, a 40673 RCA dual-gate-protected MOSFET transistor which provides high input impedance and a useful amount of gain at a very low price. The input signal from the HI-LO input switch is applied to Gate G1 through a 100K current limiting resistor. Because of the diode-protected gates, the 100K resistor allows inputs up to 50V without damage to the FET.

The 5K bias potentiometer varies the bias voltage to gate G2 to allow the Schmitt trigger, IC1, to operate in the middle of its range. The pot should be adjusted so the voltage on the FET drain is about +1.3V with no signal.

The 0.1 μF dc blocking capacitor reduces response below about 20 Hz. For operation below this frequency the capacitor could be bypassed, but it performs a valuable function of preventing external dc voltages from changing the bias on Q1.

VHF Pre-scaler (Fig. 4)

The VHF pre-scaler accepts input signals from the low rf range up through about 200 MHz – depending on the IC's you get – and divides the input frequency by 10. This is done by two special-purpose – and expensive – IC's.

IC2 is a high-frequency amplifier which allows the use of quite low voltages. It is not really needed. In fact, to get the scaler to work at 300 MHz and slightly above, it shouldn't even be used, since it limits the high frequency response. But it is very useful at lower frequencies, below about 180 MHz, and it provides a good buffer for the really

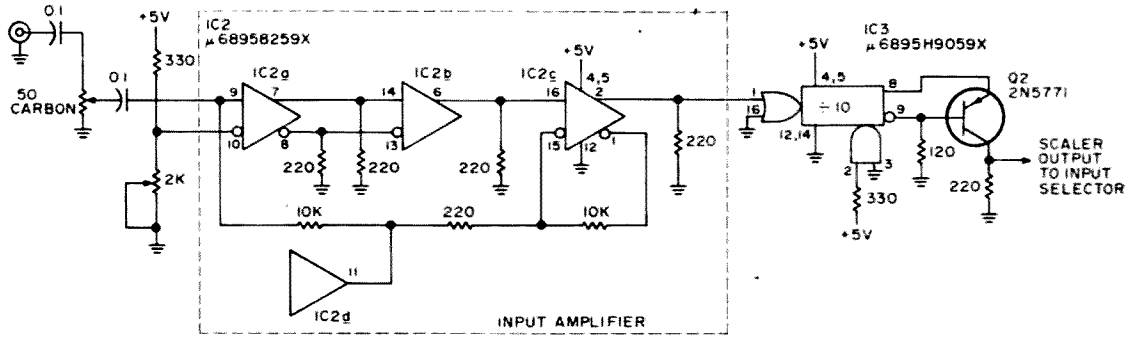

Fig. 4. VHF Prescaler. NOTE: to extend scaler range to 300 MHz (with some loss of sensitivity) eliminate all parts in dashed box, and jumper pins 2, 9, and 10 at IC2 socket.

expensive IC3 against burnout due to high input voltages.

IC3 is a special VHF prescaler IC made by Fairchild just for this use. It replaces four separate IC's used in some scalers, and even at $16 is actually cheaper than the four IC's it replaces. This particular IC is rated to work up to about 320 MHz, and some samples may work even higher than that.

These two IC's are ECL (emitter-coupled -logic) IC's, which need special interfacing with the rest of the counter, which uses TTL IC's because of their much lower cost. This is done by Q2, a level shifter and amplifier stage.

Input Selector (Fig. 5)

At first glance, the input selector may seem a little overdesigned. Sure enough, it could be replaced by a simple SPDT switch to select the output of either the low frequency input circuit or the VHF prescaler and feed it to the counters. But to avoid problems, that switch would have to be mounted right on the p.c. board, near the circuitry connected to it, and away from the input leads to prevent the possibility of feedback oscillations. To avoid the whole problem of shielding the leads and switch,

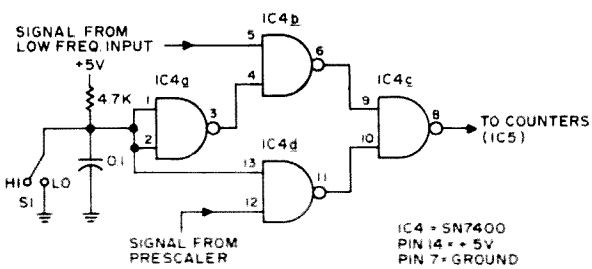

Fig. 5. Input selector.

we simply add IC4, a quad 2-input *nand* gate IC costing less than 40¢, which does the actual switching. Now a simple SPST contact on the HI-LO switch controls a small dc voltage, which energizes *either* gate IC4*b* or gate IC4*d*. A commercial counter would probably solve this problem by using a two-deck rotary switch with five inches of shaft separating the two decks, with the front deck switching the inputs between the two input circuits, and the rear deck, neatly positioned just above the circuit board, controlling the outputs. But for our purposes using IC4 is a lot more practical unless you have a switch factory next door.

Incidentally, we are going to use this trick one more time later, in the time base selector, where an SPST switch and two 40¢ IC's do the work of a DPDT switch, five coax leads, and a lot of headaches.

Counters, Latches, Decoders and Overflow (Fig. 6)

Now we come to the heart of the counter, where the actual counting is done. This circuit is divided into five almost identical stages, one for each digit displayed, plus three extra flip-flops. Most of the work is done by three types of MSI IC's. The five SN7490 IC's (IC6, IC9, IC12, IC15, and IC18) are decimal counters which count, digit by digit, the actual number of input cycles.

As soon as a count is completed, it is transferred into the five SN7475 latches (IC7, IC10, IC13, IC16, and IC19) when a strobe pulse arrives from the control circuits. These latches act as temporary memories to allow nonflickering display of the count even while the counters are reset back to

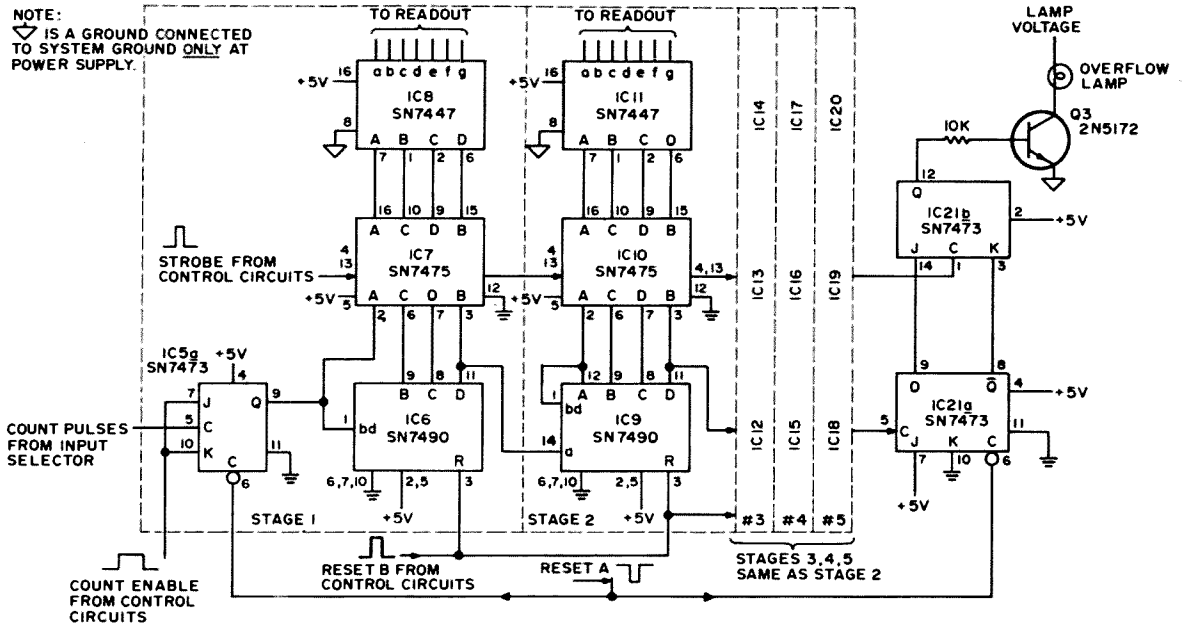

Fig. 6. Counters, latches, decoders, and overflow.

zero by a pulse on the reset B line, and then take the next count.

The BCD (binary-coded-decimal) digit from each latch is connected to the SN7447 decoders (IC8, IC11, IC14, IC17, and IC20), which translate the BCD code into the seven-segment code needed by the readouts.

The five stages of the circuit are the same except for stage 1. Part of IC6 (using pins 12 and 14) is instead replaced by an external flip-flop, IC5a. This is done because we need a foolproof way of enabling and disabling the counter for a 1-second (or 1 millisecond) intervals without disturbing the count or adding extra pulses. This is done by the Count Enable signal applied to the J and K inputs of IC5.

IC21 keeps track of any overflow from the last decade counter, IC18. If the number of cycles counted during the time period exceeds 99,999, IC18 sends a pulse to pin 5 of IC21*a* which turns on. IC21*b* acts as a one-bit latch which then remembers this condition, and lights the overflow light through Q3.

IC5 and IC21 are reset by the Reset A pulse when the counters start on a new count.

10 MHz Crystal Oscillator (Fig. 7)

The basic time reference for the counter is an AT-cut series-resonant 10 MHz crystal in a simple circuit using four gates from an SN7400 IC. Although a 2 MHz or even 100 kHz crystal could be substituted (with the saving of one or two SN7490 IC's in the time chain divider), it appears that 10 MHz crystals are more stable and need less temperature compensation. Besides, the 10 MHz crystal provides a better signal for zero-beating against 10 MHz WWV.

Time Chain Dividers (Fig. 8)

The 10 MHz signal is divided down to 1 kHz, 10 Hz, and 1 Hz by seven identical

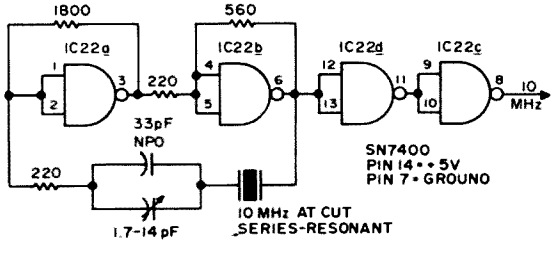

Fig. 7. 10 MHz crystal oscillator.

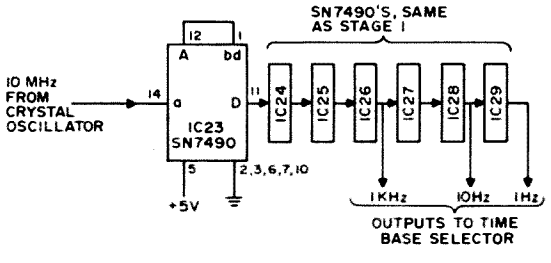

Fig. 8. Time chain dividers.

SN7490 decade counters. As mentioned above a 1 MHz crystal could be used, in which case simply omit IC23 and jumper pins 11 to 14 in its place.

Incidentally, this is a good place to get accurate frequency markers for calibration; here is a partial list of frequencies available, and where to get them:

10 MHz	IC23	pin 14
(Zero-beat against WWV, 10 MHz)		
5 MHz	IC23	pin 12
(Zero-beat against WWV, 5 and 15 MHz)		
1 MHz	IC23	pin 11
100 kHz	IC24	pin 11
50 kHz	IC25	pin 12
10 kHz	IC25	pin 11
5 kHz	IC26	pin 12
(Zero-beat against CHU, 7335 kHz)		

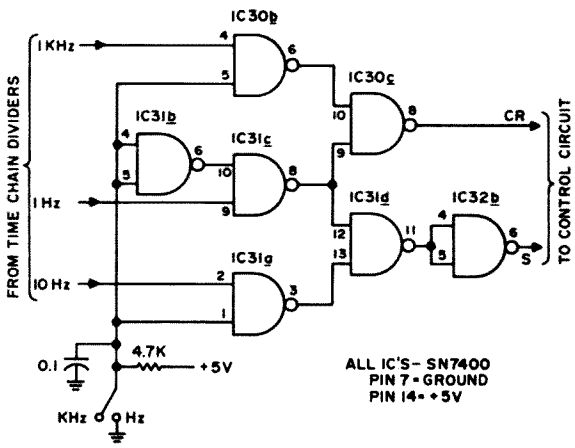

Fig. 9. Time base selector.

Time Base Selector (Fig. 9)

The time base selector receives 1 kHz, 10 Hz, and 1 Hz square waves from the time chain dividers, and sends two signals, depending on the position of the Hz-kHz switch, as follows, to the control circuits:

Switch Position	CR Output	S Output
Hz	1 Hz	1 Hz
kHz	1 kHz	10 Hz

As mentioned earlier, the switching function could just as well be done with a DPDT switch, but this would require more wiring, coax cable, and even so might cause some problems. At the expense of two IC's (IC30 and IC31, about 80¢), we simplify the wiring and eliminate some headaches as well.

The CR signal at 1 Hz or 1 kHz is eventually used to enable and reset the counter, while the S signal is eventually used to strobe data into the latches.

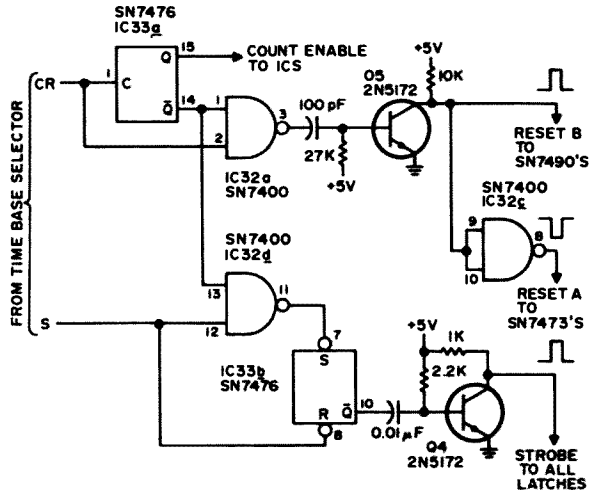

Fig. 10. Control circuits.

Control Circuits (Fig. 10)

The control circuits receive the CR and S outputs from the time base selector, and generate the count enable, resets, and strobe signals for the counters and latches.

The best way to understand the operation of this part of the counter is to look at the waveforms generated. Figure 11 shows the various signals which exist when the Hz–kHz switch is in the Hz position (they are slightly idealized – they don't always look quite so neat).

In the Hz position, the CR and S inputs are both 1 Hz square waves, though they are

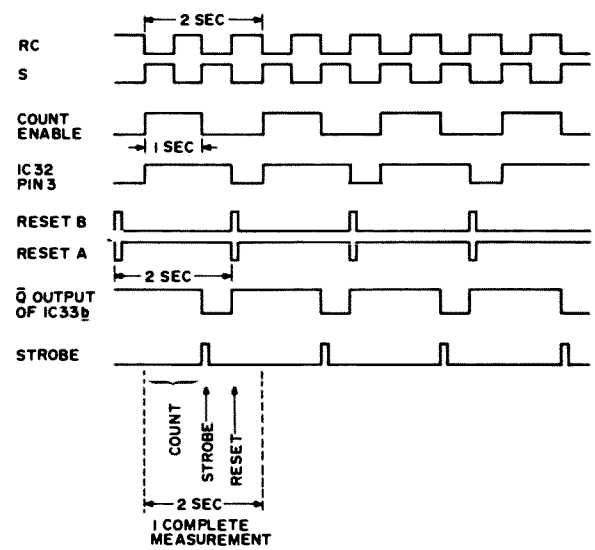

Fig. 11. Control circuit waveforms in the Hz measurement position.

out of phase. The count enable flip-flop, IC33*a*, flips back and forth at a rate of one cycle every 2 seconds. One complete measurement takes 2 seconds, as shown. First, the count enable signal goes plus for one second, during which time the counters count the input cycles. At the end of the first second, the count enable signal returns to zero, and a short positive strobe pulse strobes the counter outputs into the latches. A half-second later the reset A and reset B pulses reset the decimal counters and overflow flip-flop, in preparation for the next count.

In other words, although the actual count interval takes only one second, a complete measurement takes two seconds, and the decimal readout is updated only once every two seconds.

As shown in Fig. 12, the control circuits work quite differently when the Hz–kHz switch is in the kHz position. The count enable flip-flop, IC33*a*, flips back and forth and goes through a complete cycle in two milliseconds. The counters count the input frequency for one millisecond, then the count enable signal returns to zero, and the counters stop. One-half millisecond later the counters are reset back to zero, in preparation for the next count. In other words, the counters take 500 complete counts per second, each cycle of counting taking a total of two milliseconds.

But the big difference is in the strobe pulse. Instead of coming every two milli-

seconds, strobe pulses come only 1/10 second apart, ten per second. Thus, even though the counters take 500 counts a second, only every fiftieth count is actually displayed. A complete measurement therefore takes a tenth of a second.

This is done intentionally, to make sure that the display flickers at a 10 Hz rate if the frequency is changing. This is important when seven-segment readouts are used. Suppose the frequency is changing very quickly. As it changes, all seven elements in each readout will be turned on, in different combinations. If this happens very fast, it appears that all the segments are lit – the readout contains all 8's. For instance, suppose that the frequency measured is 16,999,500 Hz. In the kHz position, the display will read either 16999 or 17000. If it alternates very quickly between the two readings, then all seven segments in the rightmost four readouts will be lit, and the readout will look like 18888. The control circuits purposely slow down the readout strobe rate to make sure that the readout flickers between the two values at a noticeable rate.

Types of Readout Devices

Several different readout devices can be used with this counter, depending on your desires and the condition of your wallet.

The pc board is designed for the SN7447 BCD-to-seven-segment decoders and the RCA DR-2010 Numitron indicator tubes. The interconnections between these two units are shown in Fig. 13. The Numitron tube is a 9-pin miniature glass tube with seven thin lamp filaments, viewed from the side, which plugs into a 9-pin p.c. mount socket. It *could* be soldered directly to the board, but that's not a good idea since one of the seven filaments may burn out. Because the readout is viewed from the side, it's entirely practical to put the tube right on the p.c. board, and mount the board horizontally in a cabinet. The decimal digits are 0.6 in. tall and quite bright. The price of one readout tube is about $4.50 at the time of writing, making the total for five tubes about $22.50.

A slightly cheaper seven-segment miniature readout device has been advertised in

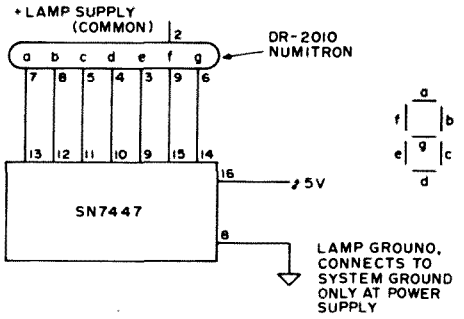

Fig. 13. Connecting the RCA Numitron (DR-2010) readout.

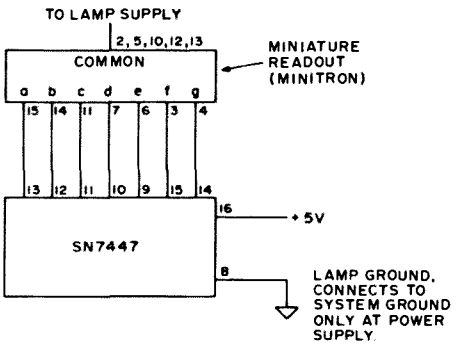

Fig. 14. Connecting the 16-pin miniature incandescent readout.

several ham magazines under various names. It works on the same principle as the Numitron, but is mounted in a tiny 16-pin package similar to a 16-pin I.C., with the numbers only 0.36 in. high. At the time of writing its price is about $3.70, or about $18.50 for a set of five. It can be connected to the SN7447 decoder as shown in Fig. 14.

Both of these readouts have one slight problem. At an applied voltage of 5V, the current per segment in the Numitron is 25 mA, and about 8 mA in the smaller readout, while the SN7447 decoder IC is rated to deliver up to 20 mA. But the surge current into an incandescent lamp filament when first turned on is about 12 times the rated current – the Numitron takes about 300 mA surge, while the miniature type takes about 100 mA. Both of these values can overload the SN7447.

One way to avoid this problem is to use the SN7447A decoder, which is rated for somewhat more current than the SN7447. Another is to use less than 5V. Some people suggest that the lamp voltage be taken from an unregulated 3–4V. An excellent choice is a full-wave rectified, but unfiltered, 3.15V (see Fig. 17 for power supply connections).

Another problem is associated with the high surge currents. The lamp voltage and the ground connection for the SN7447 must go directly to the power supply, separate from the normal power leads for the rest of the unit.

A really elegant, though more expensive method is to use a light-emitting-diode seven segment readout such as Monsanto's MAN-1, or -3, the Litronix 10A, or some of the Hewlett-Packard units. At the time of writing the minimum cost in unit quantities is about $8.50 each ($42.50 for a set of five), but many people feel that by the time this article appears the LED price may be close to the incandescent readouts.

The MAN-3 has a number height of about 0.1 in. while the MAN-1 and Litronix 10A are about 0.3 in. Figure 15 shows the connections from the SN7447 to the MAN-1 or 10A. Both LEDs are mounted in a miniature 14-pin package similar to a 14-pin IC.

Both the LED readout and the miniature incandescent readout are IC-like packages which have to be viewed from *above*. This means that it's not practical to mount them

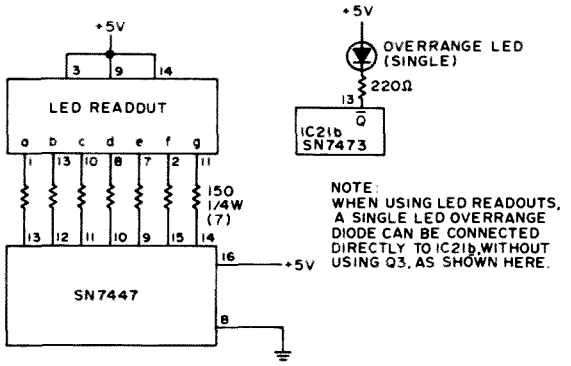

Fig. 15. Connecting the MAN-1, 10A, and LED-700 LED readouts.

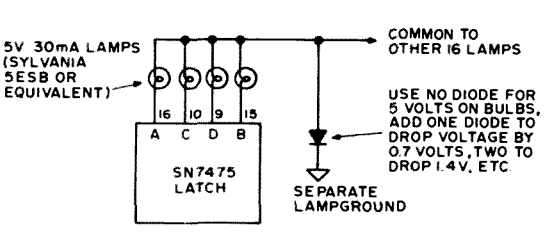

Fig. 16. Connecting four lamps to SN7475 latch, to reduce cost.

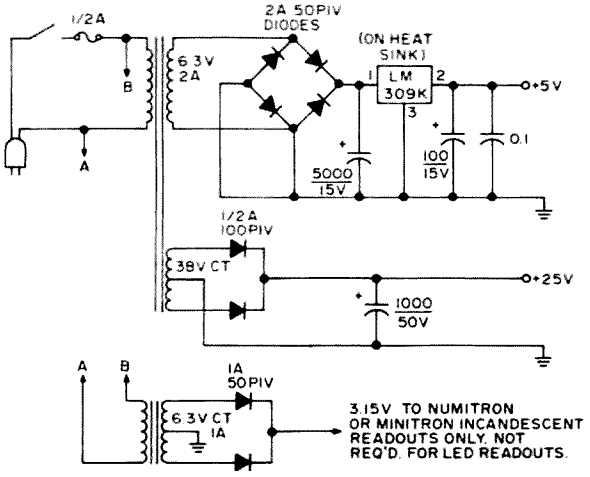

Fig. 17. Power supply.

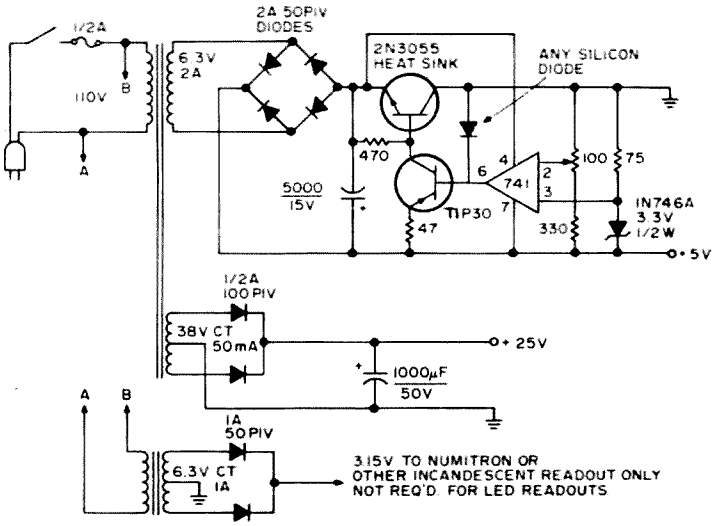

Fig. 18. Alternate power supply.

on the same board as the rest of the counter unless you like to look down from above. The best way to mount them is on a small etched or perforated board which stands up vertically right in front of the main p.c. board.

Power Supply (Figs. 17 and 18)

A good power supply is a very important part of any digital system. It must be well filtered and well regulated, since integrated circuits are very sensitive to noise on the power lines. Most important, the power supply voltage to the IC's should be between +4.75 and +5.25V, and must not go above 5.5V or so to avoid damage to them.

The counter needs +5V at ±5% regulation at about 1.5A, +25V at about 10 mA for the FET input amplifier, and a lamp voltage of about 3V and roughly 1A if incandescent readouts are used (LED readouts work directly off the +5V supply).

The simplest +5V power supply uses an LM-309K 5V regulator IC, available from a number of sources at a low price. Shown in Fig. 17, all it has is a bridge rectifier, three filter capacitors, and the regulator. Figure 18 shows an alternate design, which is capable of somewhat more current output and therefore runs cooler. This design happens to be the one used in our prototype, since it is current limiting and short-circuit proof.

In our units, the +25V supply uses a 38V center-tapped transformer winding and a simple full-wave rectifier. Since only about 10 mA of current is required, a 1000 μF filter capacitor is enough filtering. Since 38V transformers are not that common, you may use a 16V bell transformer in a bridge rectifier circuit to give the same output voltage; the p.c. board has room for the extra two diodes in the bridge. In fact, any transformer that will provide 20–30V of dc will work. Regulation is not too important.

If you use the Numitron or Minitron incandescent readouts, the 3V lamp voltage comes from a separate 6.3V center-tapped filament transformer, as shown in Figs. 17 and 18. The two rectifier diodes mount on the main p.c. board. If you use the LED readouts, the transformer and diodes are not needed.

Since the TTL IC's are not only sensitive to noise, but generate sharp spikes on the 5V power line as well, adequate filtering is very important. In addition to a hefty power supply filter capacitor, there are small 0.1 and 0.01 μF disk capacitors scattered around the p.c. board, bypassing the +5V line to ground. These are essential to eliminate the voltage spikes as close to the IC's as possible. In fact, the two IC's in the VHF prescaler have 0.01 μF disk capacitors soldered directly under them, on the copper side of the board, connected right on the two power supply pins, just to keep out noise and prevent problems.

In the third part of this article, we will show you how the p.c. board is laid out, where to place the parts, and how to hook the whole thing up.

EXPERIMENTAL SOLID STATE VHF AMPLIFIER

A couple of articles in the amateur literature have outlined the merits and characteristics of some of the relatively new power transistors for VHF power amplification.[1,2] The article by Franson is extremely valuable; it describes characteristics and typical circuits with a good section on impedance matching between stages and to the output load.

After careful reading of some of the published information, a 2N3866 transistor was obtained. This type was selected mainly because of its low cost and 1W output rating. A watt of output at 2 meters puts a solid state transmitter in pretty much the same class as the little transceivers so popular for local contacts on the band.

While the circuit designs have been worked out on paper, not much has been shown on the practical construction methods required to obtain maximum efficiency in a power amplifier stage. A quick check in breadboard fashion showed that the 2N3866 would indeed provide considerable power gain at 144 MHz, and seemed to be quite stable in operation. For the preliminary test, the transistor was mounted inside a small minibox with the emitter lead soldered directly to a ground terminal bolted to the chassis, and the other two transistor leads soldered to standoff terminals close to the transistor body. Input and output jacks were mounted on each end as well as a feedthrough capacitor on the top of the box for the application of B-plus. This arrangement provided a check on the circuit, but the power output obtainable was well below what the data sheet indicated it should be.

Both articles mentioned point out the necessity of using the shortest possible leads in the construction of this type amplifier, and indicate the construction which should be used for maximum efficiency at VHF. It

was obvious that the breadboard amplifier did not meet these requirements, especially in regard to grounding the emitter lead by as direct a path as possible. The emitter lead was probably somewhat over an inch in length after passing through the solder lug to the chassis ground. Also, the tank coils and rf choke in the base circuit were not mounted as they should have been.

With these inefficiencies in mind, the circuit board pattern shown in Fig. 2

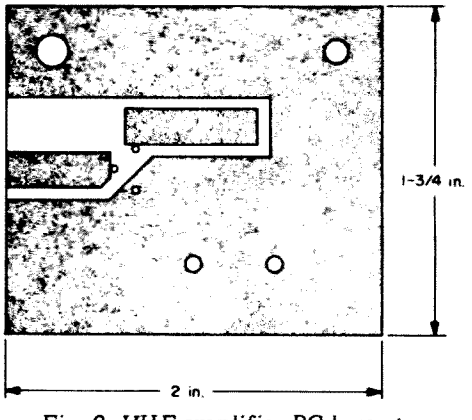

Fig. 2. VHF amplifier PC layout.
40% of original size (shoot at 250% to make this layout 2.775 times larger than shown).

evolved. The copper clad board provides a good ground plane for the amplifier, and soldering the transistor directly to the board provides the shortest possible leads, especially for the emitter termination. The wide strips of copper at the collector and base connections give low inductance connections at these points, another consideration mentioned in both articles.

As shown in the top view of the assembly (Fig. 1B) the input jack is soldered directly to the base connection on the circuit board and also serves as a support for the board on this end. The other end of the board is supported on a grounded standoff. It was thought best to use just one standoff between the circuit board ground pattern and the main minibox chassis ground, although the effects of ground loops with a more rigid multiple point mounting were not investigated. At any rate, the construction method shown is plenty rigid, even for mobile applications in amateur service.

C2 is soldered directly to the collector strip on the circuit board eliminating a lead at this point, and L2 goes between the other side of C2 and the output port. The output loading capacitor, C3, is a piston trimmer with one side bolted directly to chassis ground. A flat strip of 1/8 in. copper was used for the short connection from the high side of C3 to the output.

The amplifier circuit was the same as the one in Fig. 4A in the article by Franson. This particular circuit is a good choice to obtain an impedance match between the collector and the 50Ω output desired, since the impedance level at the collector is pretty much set by the supply voltage and power output level, in this case somewhere in the area of 12V and 1W of output. The circuit is repeated in Fig. 1A.

With the amplifier built on the circuit board, and mounted inside the minibox, the power output available immediately jumped up to 1W or more. Best of all, the amplifier tuned up and acted just like one might on the low frequency bands.

In order to run the transistor at the relatively "high" level necessary for a watt of output, some sort of heatsink for the transistor should be provided. A flat plate of

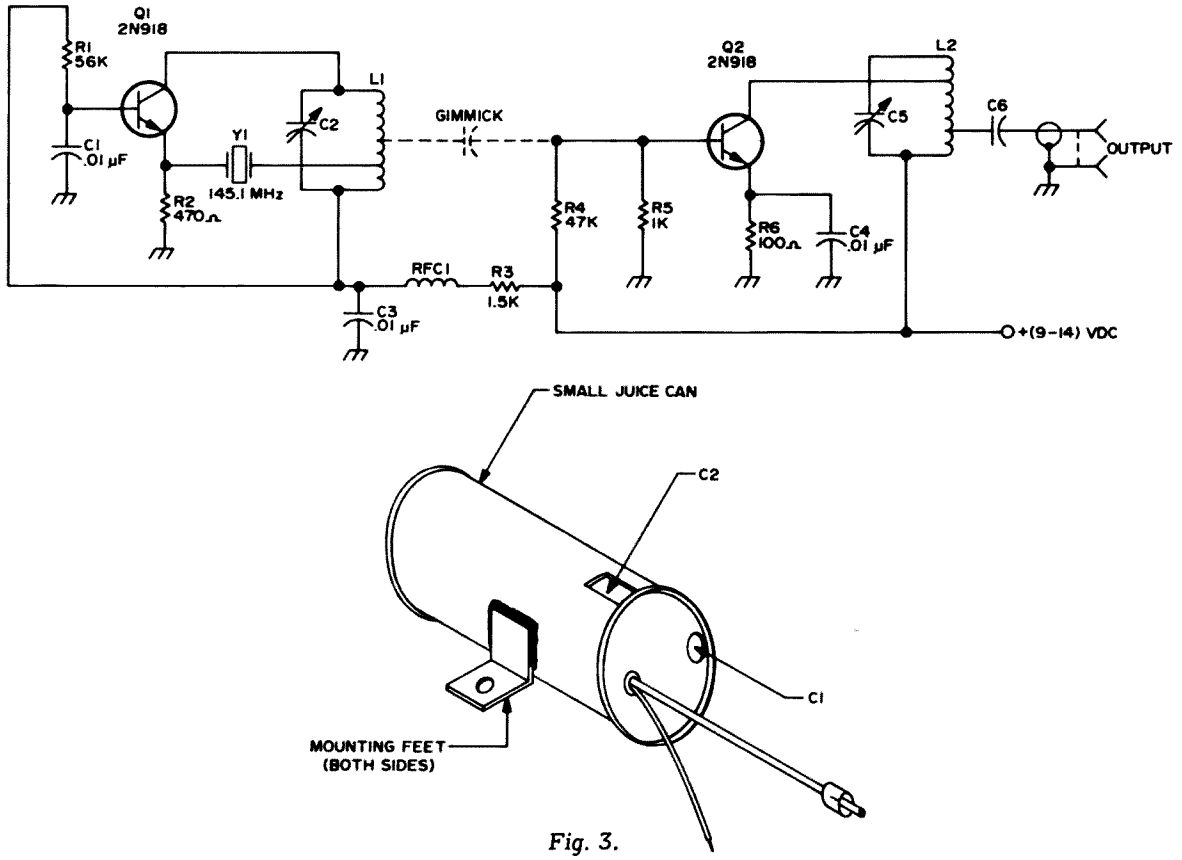

Fig. 3.

aluminum was tried by reaming a hole to fit over the transistor body and bolting it directly to the circuit board. However, this arrangement added so much capacity from collector to ground that the circuit failed to work with the heatsink in place.

As a result, a small heatsink clip was fashioned from scrap metal to slip over the transistor in much the same manner as the commercial clips available. This radiator provides enough cooling for normal power levels. The output flattens out above a watt anyway, so there is no advantage in pushing the stage any further than a couple of watts of dc input. Actually, the transistor ratings indicate that it could probably be operated at this level without a heatsink, although the clip is insurance well worth the effort.

As it turns out, actual checking of amplifier performance is simple with this type of construction, and in many amateur applications the source of a signal to drive the stage may be more difficult to obtain. For quick checks the output from a small two-meter transmitter could be used with a suitable attenuator to knock down the power to the few milliwatts required.

As a matter of interest, the circuit of a little 144 MHz signal source is shown in Fig. 3. This was built up on a small piece of vectorboard and mounted inside a small frozen orange juice can. It provides a very convenient signal source with a few milliwatts of output, which is just right to drive something like the 2N3866. The critical part of the signal generator, of course, is the 145 MHz overtone crystal.

The test amplifier shown not only provides a convenient and efficient way of checking transistor performance, but it can be used as an integral part of a small two-meter transmitter. With a crystal oscillator like that in Fig. 3 and a small modulator, the 2N3866 amplifier provides a simple little transmitter with results equivalent to some of the small commercial two-meter rigs. The applications for mobile and portable work are obvious.

THE PHASE-LOCK LOOP

PART ONE

Reprinted from Amateur Radio, *Journal of the Wireless Institute of Australia.*

This is the first of two articles written with a view to acquainting amateurs with the principles of the phase-lock loop. Applications of the phase-lock loop are outlined and the use of a phase-lock loop as an optimum FM discriminator is discussed.

The basic phase-lock loop is shown in block diagram form in Fig. 1. It comprises three basic components:

(1) A phase detector (Fig. 2),
(2) A low pass filter (Fig. 3),
(3) A voltage controlled oscillator (VCO) (Fig. 4).

The phase of a periodic input signal and that of the VCO is compared by the phase detector; output of the phase detector is a measure of the phase difference between its two inputs. This difference voltage is then filtered by the loop filter and applied to the VCO. Control voltage on the VCO changes the frequency in a direction that reduces the phase difference between the input signal and the VCO.

When the loop is "locked" the control voltage is such that the frequency of the VCO is exactly equal to the average frequency of the input signal.

Suppose now that the input signal carries information in its phase or frequency; this signal is inevitably corrupted by additive noise. Suppose also that the VCO is the "local oscillator" in some form of receiver. The task of such a phase- lock "receiver" is to reproduce the original signal while removing as much of the noise as possible. If the "local oscillator" could be locked to the input signal and made insensitive to the random noise on this signal, then the input signal could be reconstructed.

The input to the loop is a noisy signal, whereas the output of the VCO is a cleaned-up version of the input. To suppress noise, the error output signal from the phase detector is averaged over some length of time by the loop filter, and the averaged error is then used to control the frequency of the oscillator. It is reasonable, therefore, to consider the loop as a kind of filter that passes signals and rejects noise.

Two important characteristics of the filter are that the bandwidth can be very small

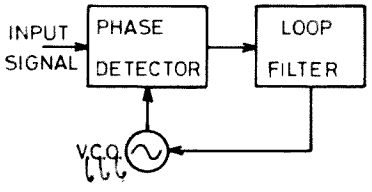

Fig. 1. Basic phase lock loop.

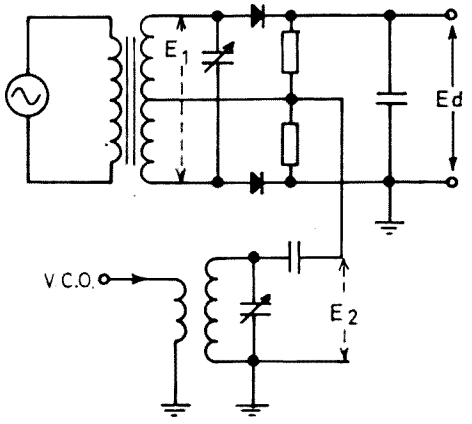

Fig. 2. Typical phase detector. If the signal input is Er sin (2 π ft) and the VCO is E2 cos (2 π ft + o) then the output of the detector is Ed≈ 2E2 sin θ or for small θ, Ed ∝ E2 θ for E2 > E1, i.e. the output voltage is proportional to the phase difference between the signal input and the VCO.

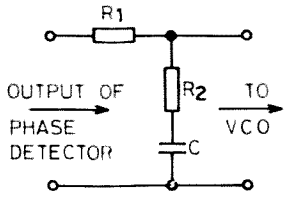

Fig. 3. Typical low pass filter. The transfer function of this filter is

$$H(S) = \frac{S\,C\,R2 + 1}{S\,C\,(R1 + R2)} + 1$$

where S is the complex variable.

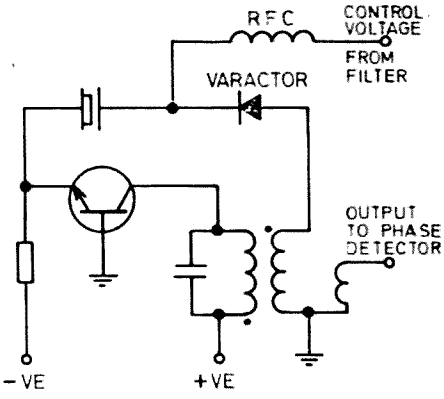

Fig. 4. Typical voltage controlled oscillator.

and the filter automatically tracks the signal frequency. Narrow bandwidth is capable of rejecting large amounts of noise; it is not at all unusual for a phase-lock loop to recover a signal deeply embedded in noise.

One application of the phase-lock loop is as the local oscillator in a synchronous or homodyne receiver. In essence this receiver consists of nothing but a local oscillator, a mixer, and an audio amplifier. To operate, the oscillator has to be adjusted to exactly the same frequency as the carrier of the incoming signal which is then converted to an intermediate frequency of zero Hz. Output of the mixer contains demodulated information that is carried as sidebands by the signal. Correct tuning of the local oscillator is essential to synchronous reception; any frequency error whatsoever will hopelessly garble the information. Furthermore, phase of the local oscillator must agree, very closely, with the received carrier phase. In other words. the local oscillator must be phase-locked to the incoming signal.

Another common application arises in television receivers. The flywheel synchronisers in present-day TV receivers are really phase-locked loops.

Space use of phase-lock began with the first American (Russian?) artificial satellites. These carried 10 mW. CW transmitters; received signals were correspondingly weak. Furthermore, Doppler shift made the exact frequency uncertain. At the 108 MHz frequency used, the Doppler shift could range over a ±3 kHz interval. Hence an ordinary fixed-tuned receiver would require at least a 6 kHz bandwidth for a signal that could be contained in something like a 6 Hz bandwidth. This entails a noise penalty (noise is directly proportional to bandwidth) of 1,000 times, i.e. 30 dB. Such penalties are intolerable and that is why narrow-band phase-locked tracking receivers are used.

Noise can be rejected by a narrow-band filter, but if the filter is fixed, the signal will almost never be within the passband. For a narrow filter to be usable it must be capable of tracking the signal. A phase-locked loop is capable of providing both the narrow bandwidth and tracking that are needed. Current applications of phase-lock include:

(1) Perfect afc (automatic frequency control) of receivers;

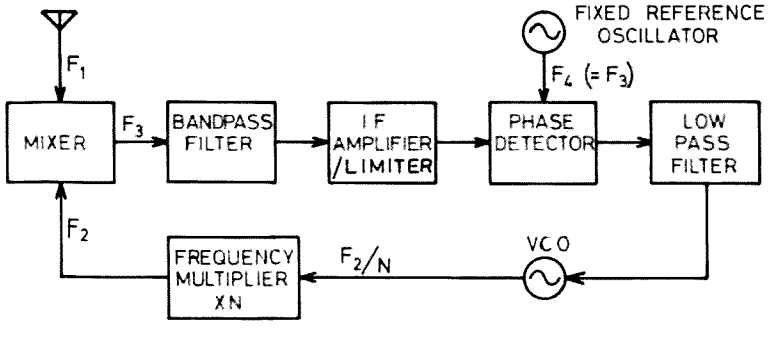

Fig. 5. Basic phase-lock receiver.

(2) P.c.m. telemetry bit synchronisation;
(3) Frequency multipliers and dividers;
(4) Coherent transponders;
(5) Noisy oscillators can be enclosed in a loop and locked to a clean signal; if the loop has wide bandwidth, the oscillator tracks out its own noise and the output is greatly cleaned up.
(6) A phase-locked loop can be used as a frequency demodulator; in which service it gives superior performance to conventional discriminators.

A simplified diagram of a superheterodyne phase-lock receiver is shown in Fig. 5. The principal difference between this and a conventional receiver is that the local oscillator tracks the input signal, allowing a much narrower i-f bandwidth. The smallness of the bandwidth is limited only by error and stability considerations.

Consider now the output of the phase detector; this is proportional to the phase difference between the i-f signal and that of the local reference oscillator. As the input signal varies in frequency when modulated, so the output of the phase detector will vary in sympathy with the modulation in order that the VCO track with the incoming signal to keep the frequency and phase of the i-f signal correct. Thus this voltage from the phase detector is a demodulated version of the FM signal. Direct use of the phase-detector output is unsatisfactory since it would be very noisy and unfiltered. Normally the demodulated signal is taken from the loop low-pass filter.

A simpler method for using a phase-lock loop as an FM demodulator is shown in Fig. 6; performance is of course not as good as a fully fledged phase-lock receiver, but practical advantages are obvious.

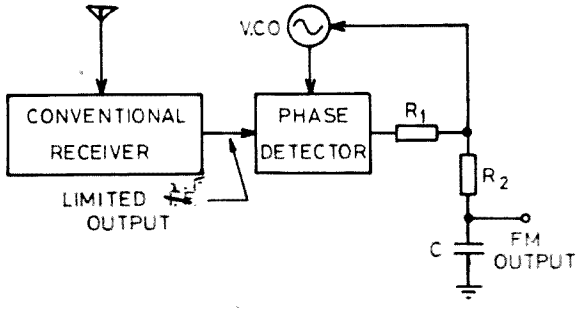

Fig. 6. Loop used as discriminator.

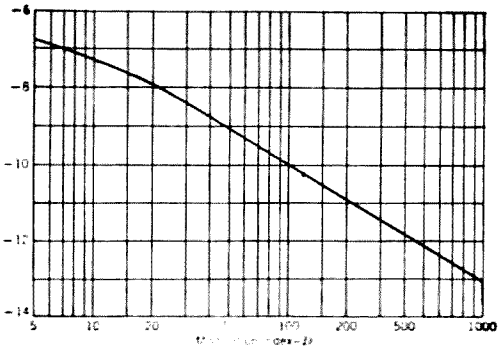

Fig. 7. Threshold for Random Modulation (Ref. 1).

The threshold of a conventional discriminator is considered to be +10fN SNR (signal-to-noise ratio) at the input to the limiter, whereas the threshold SNR for the phase-lock loop demodulator is indicated in Fig. 7.

Conclusions

The following conclusions may be drawn regarding discriminators:

(1) At high input SNR's there is no appreciable difference between phase-locked and conventional types.
(2) A phase-locked loop will have a lower threshold than the +10 dB of a conventional discriminator.
(3) The improvement that can be gained depends on the modulation of the input signal.
(4) For best results , the loop should be specifically designed for the modulation actually present.
(5) Premodulating filtering can provide better performance..

Next month, in the second article on this subject, a practical FM demodulator using an IC will be discussed. This is of the "add on" variety as in Fig. 6.

VHF CONVERTERS
A Building Block Approach

Dual insulated gate MOSFETS have taken a lot of the drudgery and black magic out of VHF front-end design. Using these devices, it is possible to construct stable, high-gain, low-noise rf amps and quiet, "birdie" free mixers using a few basic circuits without the use of exotic test equipment or hours of fiddling with temperamental adjustments.

Dual insulated gate MOSFETS offer inherent advantages not found in any other device. They handle strong signals and show cross-modulation characteristics as good as those of a well-designed pentode

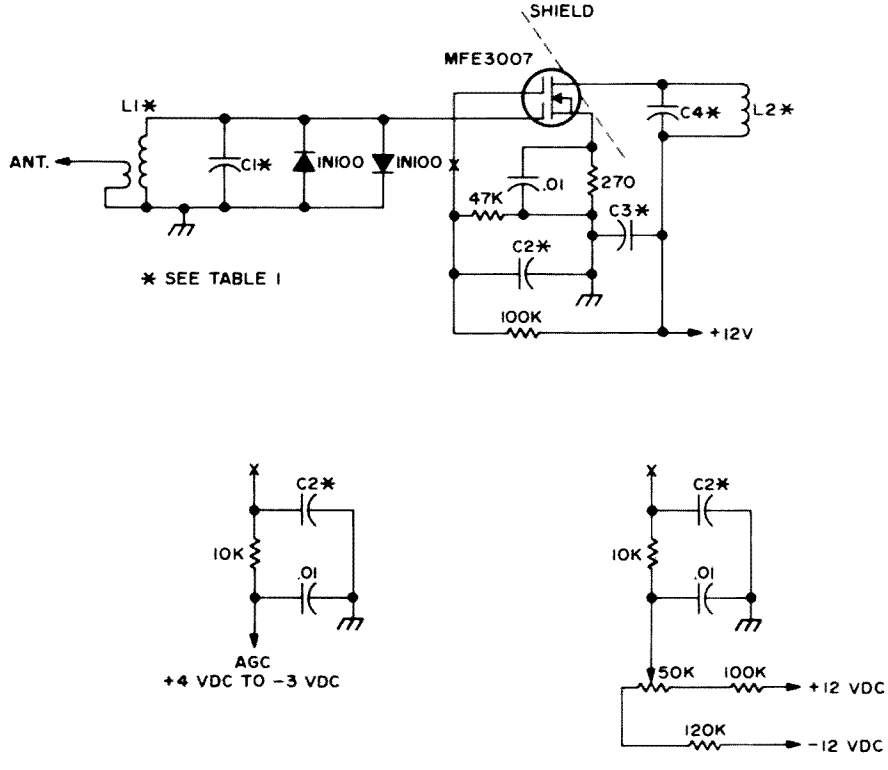

Fig. 1. RF amplifier.

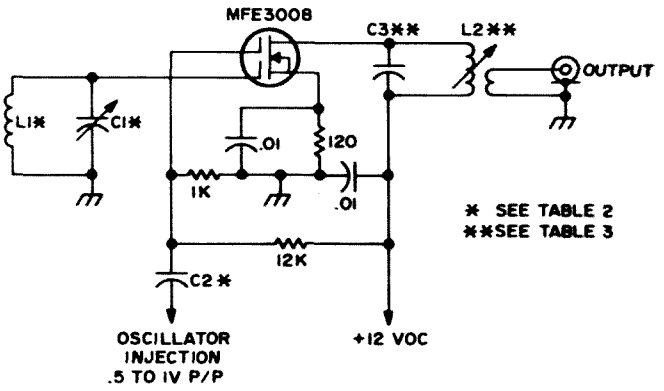

Fig. 2. Mixer.

tube stage, yet they provide noise figures and gains which cannot be excelled with anything but a parametric amplifier. They are quite stable and predictable. They have very low input and output capacitances, and are high-impedance devices, permitting comparatively easy design of tuned circuits well into the VHF range. They are relatively uniform device-to-device of the same designation, and maintain their characteristics over a broad range of frequencies. If desired, agc is easy to apply, though it will not, of course, normally be used in VHF front ends.

Because of all these advantages which are so happily combined in one family of devices, it is possible to use a building-block method for designing VHF converters and rf amps up to 432 MHz. Only the frequency-dependent components have to be changed in building over a wide range of frequencies. This has never been possible with other devices.

MOSFETS do, however, have certain limitations because of their extreme susceptibility to gate shorts caused by excessive rf voltages or static charges. Therefore, in handling and installation, it is important to circumspectly observe some precautions.

I have read of many elaborate safeguards to be taken in handling MOSFETS, including grounding the soldering gun tip

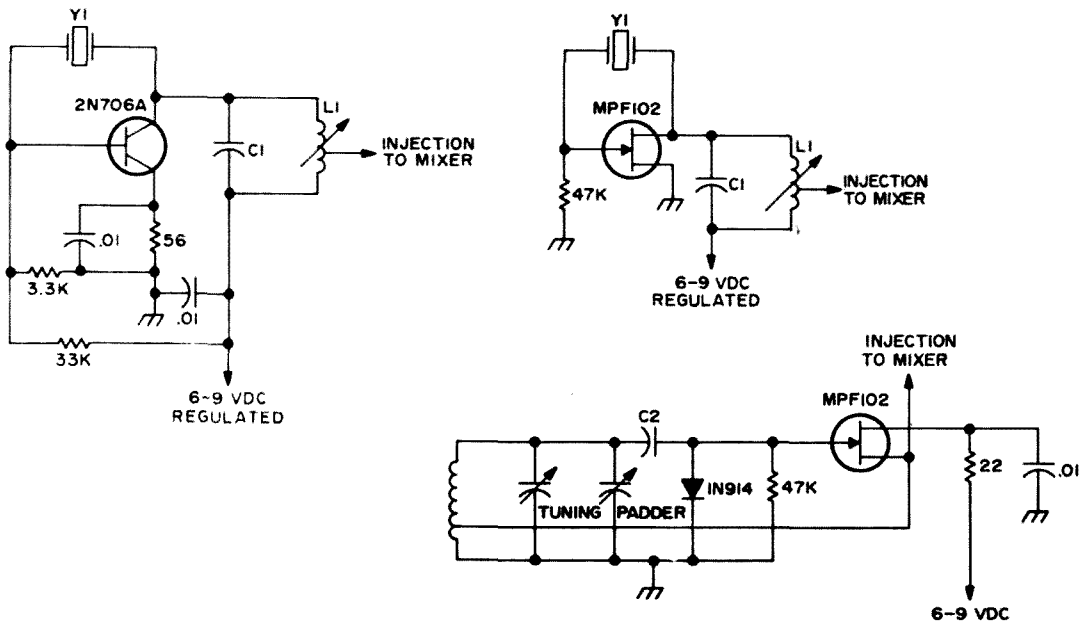

Fig. 3. Oscillators.

before soldering them in. I definitely prefer to use sockets, and with a little forethought this is possible in just about any VHF design. The use of sockets eliminates many potential hazards to the delicate MOSFET gates. NEVER INSERT OR REMOVE A MOSFET WHILE ANY VOLTAGES AT ALL APPEAR ON THE SOCKET TERMINALS!!!! Once a MOSFET is installed in a circuit, the problem of static charge damage is pretty well taken care of. But while preparing the device for installation, caution must be excercised. Even minute discharges such as those from your fingers on a dry day are dangerous. The method I use to avoid problems is so simple that it seems to have been overlooked. At least, I have never heard of it elsewhere: I use water.

Have a pan of water close by when you prepare to install a MOSFET. Before removing the packing short, immerse your hands, the MOSFET, and all tools which will contact it in the water. Since the MOSFET is hermetically sealed, it won't be damaged. Then remove the short, trim and form the leads, and insert it in the socket. Be sure you keep everything wet until it's finally installed. I guarantee you'll avoid any shorted-gate problems if you use this method.

Precautions must also be taken in the circuitry and mechanical design of equipment using MOSFETS which will be located in a strong rf field, as in a typical amateur installation. It is advisable to use *two* good relays in series between the transmitter output and the converter input to provide the greatest possible isolation from the transmitter. In the transmit position, the converter input can be shorted to ground by the extra relay. Back-to-back diodes (1N100s are fine) should be connected across the input gate of the first rf amp to limit the rf voltage appearing there to about 0.7V peak-to-peak. In addition, the lead from the input coil to the input gate and the lead from the input connector to the coil should be kept as short as possible to minimize any stray coupling. The entire converter should be carefully *sealed* to rf to keep everything out of the converter except what comes through the antenna input connector; and all stages

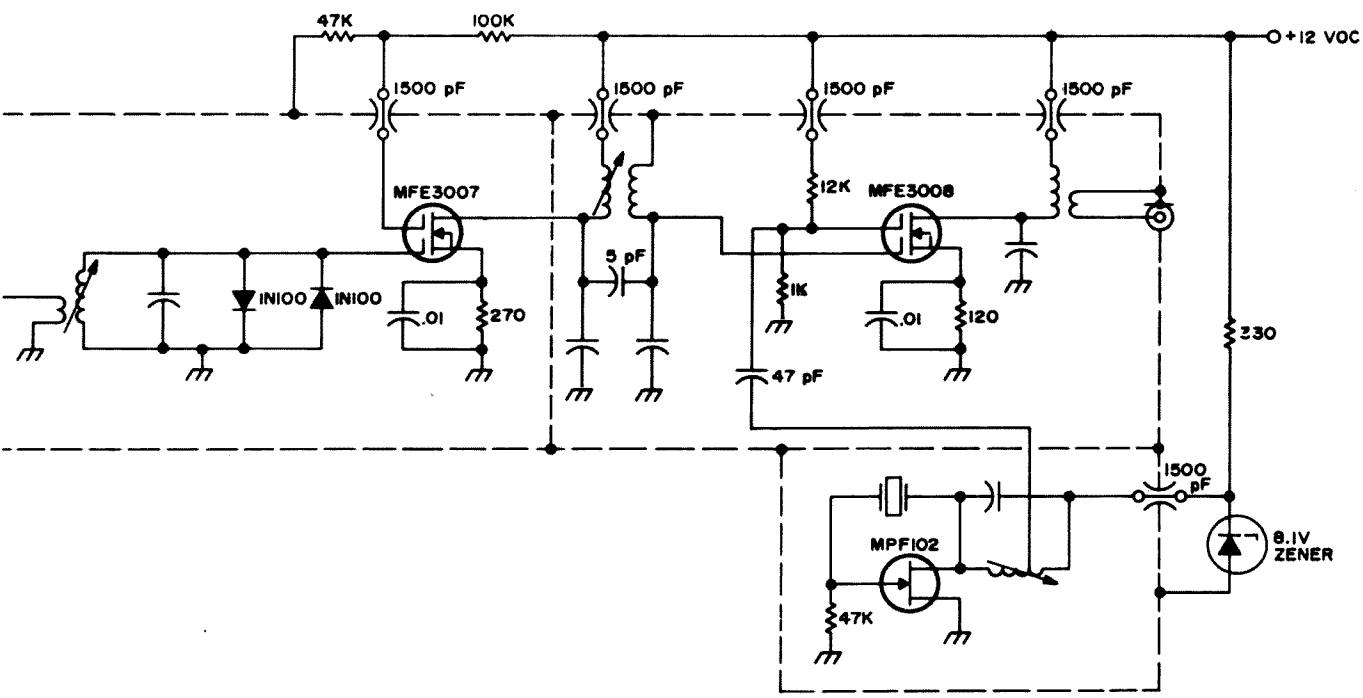

Fig. 4. 50 MHz converter. Output link should be 3 turns over output coil to match low impedance receiver input. Note the use of feedthrough capacitors for all dc voltages and shielding between all stages. Tuned circuit values will be found in Tables I–IV. Output coil of oscillator is tapped for injection voltage. It should run between 2 and 4 turns from cold end for .5 to 1V peak-to-peak, but this will vary somewhat from crystal to crystal.

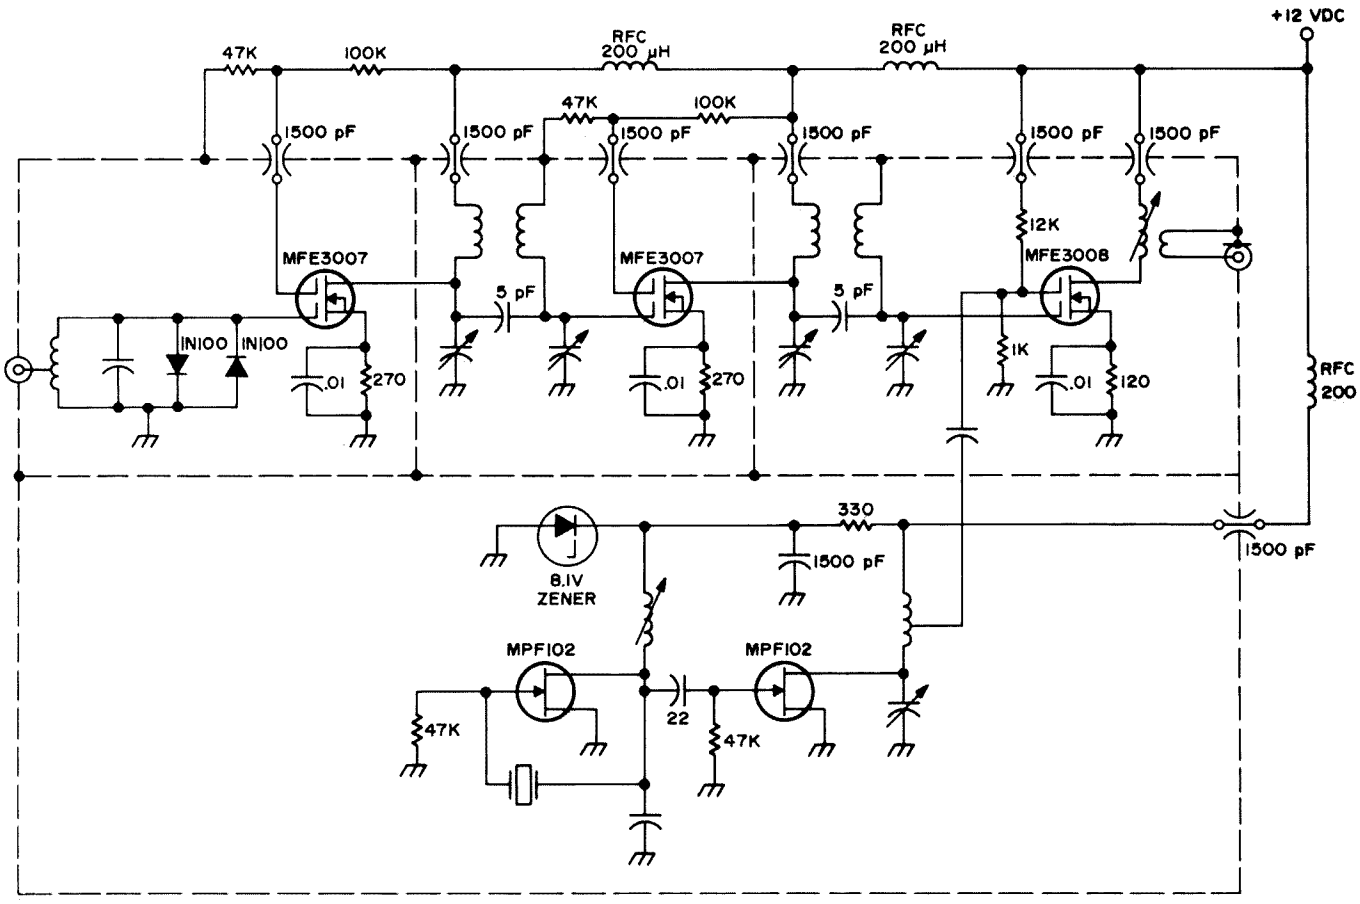

Fig. 5. Schematic of a converter for 144 or 220 MHz illustrates the use of the MPF102 JFET as a multiplier. Note that it is necessary to tap down on the coil to achieve proper injection voltage. Tuned circuit values will be found in Tables I–IV.

should be carefully sealed from one another. The converter diagrams illustrate the kind of layout required as well as the use of feedthrough capacitors.

Mixers shown use the Motorola MFE3008, while the rf amps use the MFE3007. RCA manufactures a wide range of MOSFETS which can be substituted directly for these devices, but I have found the Motorola MOSFETS easier to come by.

The basic rf amplifier building block will usually be used straight through at maximum gain in VHF installations. However, gain control options are shown. To apply them, break the lead in Gate 2 at "X" and add the circuitry shown in the

TABLE I: Rf stage components

Freq.	L1, L2	C1, C4	C2, C3	Typ. gain
50 MHz	8 turns #22, close wound on ¼" slug tuned form. Three turn link over L1 for input.	10 pF	1500 pF	24 dB
144 MHz	4 turns #20 tinned, 5/6" diameter, ½" long. Tap L1 1 turn from ground end for input.	8 pF plastic tubular trimmer	1000 pF	20 dB
220 MHz	4 turns #20 tinned, 5/6" diameter, ¾" long. Tap 1 turn from ground end for input.	8 pF plastic tubular trimmer	1000 pF	18 dB
432 MHz	#12 wire, 2½" long. Tap L1 at 1", L2 at 1 ¾". (See Fig. 9)	3 pF plastic tubular trimmer	500 pF	12 dB

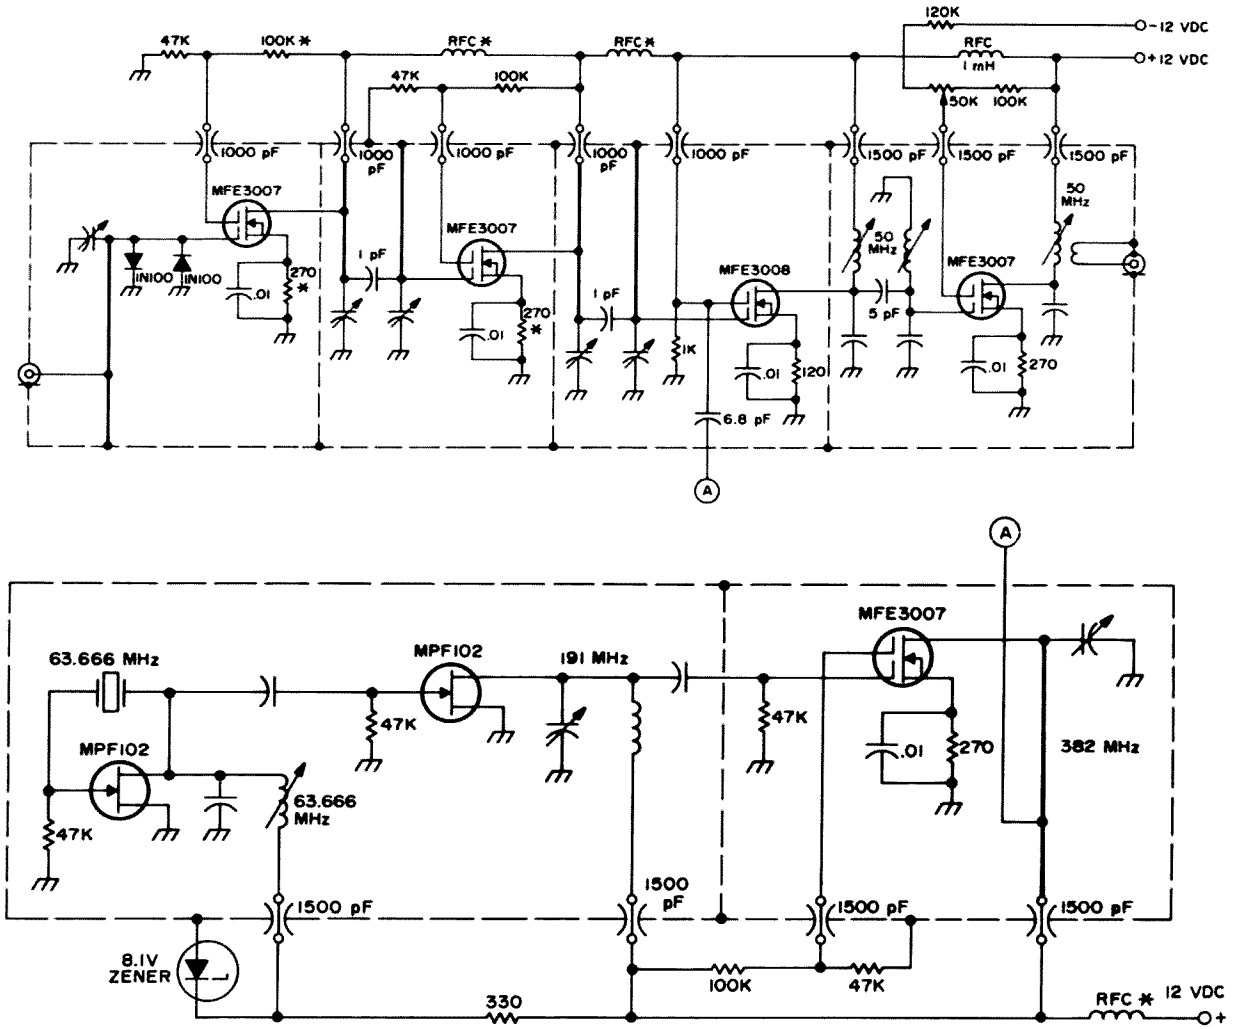

Fig. 6. 432 MHz converter illustrates the use of the MFE3007 as a doubler, to assure adequate injection voltage. Note that output to mixer is, again, tapped down on the tank coil. If leads are not kept extremely short, it may be necessary to parallel 220 pF ceramics with the .01 μF source bypasses shown. The i-f amplifier may not be necessary, particularly if the converter is used with the 50 MHz converter shown in Fig. 4. I-f gain control is optional. Tuned circuit values are shown in the tables.

options. With agc or rf gain control, the basic rf amp makes a fine i-f amp for use at low frequencies, or following a converter. Frequency dependent parts are marked with an asterisk, and values are broken down in Table I. RF stages can easily be cascaded by coupling L2 of the first stage to LI of the second stage using 2 or 3 turn links or twisted wire "gimmick" capacitors. One stage gives more than adequate gain at 6m and below, but from 2m up, two stages are advisable for optimum performance. The basic rf amp building block can also be used as a multiplier in oscillator chains, though for economy and simplicity, the MPF 102 is preferred. Typical noise figure is under 3 dB. Approximate gain figures will be found in Table I.

Components marked with a single asterisk are dependent on the input frequency, and those marked with a double asterisk are dependent on the i-f frequency. For values, refer to Tables II and III respectively. Approximate conversion gain will be found in Table II.

*RFCs are #28 closewound over 47K ½W resistors, 8 to 10 turns. Noise figure can be improved by increasing source resistance and decreasing 100K resistor to keep G2 to source voltage at approximately 4V. Maximum possible source resistance is 750Ω. There will be some compromise in gain, and the noise figure can only be decreased by 1 dB at best, so it generally is not worthwhile.

There are several possibilities for basic oscillator building blocks. There is one factor which must be taken into consideration which is often ignored: the level of the injection voltage. With MOSFET mixers, it is advisable to keep the heterodyne voltage between .5 and 1V peak-to-peak. A voltage this low will not maximize conversion gain, but it will insure minimum spurious responses. Even at .5V, there is still more than enough conversion gain – 6 to 15 dB, depending on frequency. Although it is possible to design oscillators using single- or dual-gate MOSFETs, there is nothing to be gained from the additional complexity and expense, compared to a well-designed JFET or bipolar oscillator. Of the circuits shown in Fig. 3, I have found the JFET to be the easier of the two crystal controlled circuits to get working. It seems a bit more predictable and stable than the bipolar model. A pleasant surprise was the very simple JFET vfo. It is rock stable, and the output is very clean. It is recommended for any use where a tunable front end is required, up to about 220 MHz.

Note that the output of the crystal oscillators has to be tapped down on the tank coil to keep the injection voltage down to the desired level. Component values for a variety of i-fs will be found in Table IV

Construction Notes

Use of a shield between the input and output coils of the rf amps is imperative.

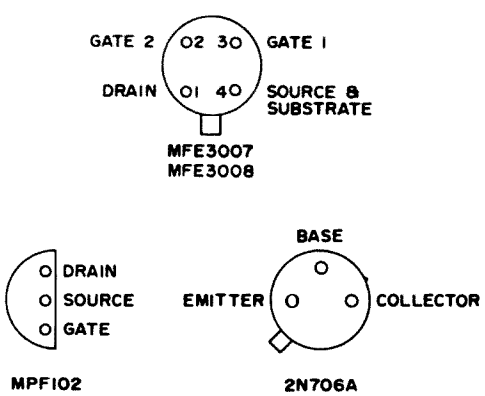

Fig. 7. Base diagrams of transistors referred to in schematics and text (bottom views).

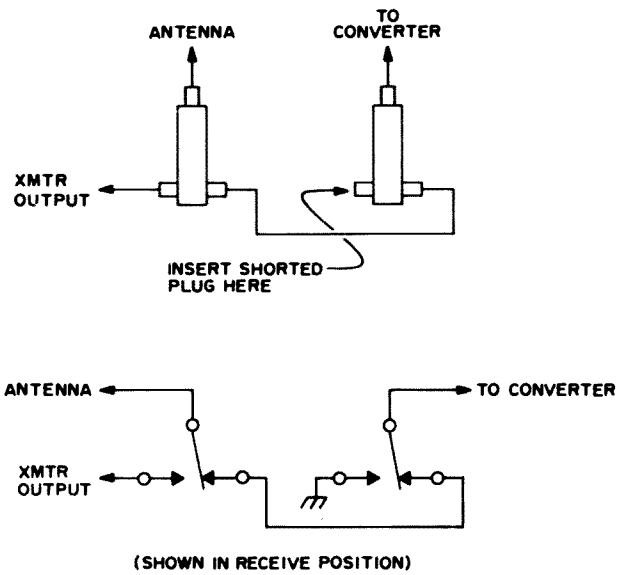

Fig. 8. Method of connecting antenna relays in series to protect MOSFET front end.

Feedtrhough capacitors are definitely recommended for everything going in or coming out (except, of course, for the signal connections). They will help eliminate another potential source of rf leakage, and instability. See the diagrams of various convertors, Figs. 4–8. Mechanical stability and sound shielding techniques must be observed to derive maximum benefit from the circuits presented here. Printed circuit techniques are not recommended because of rf leakage potential. Use copper clad board as a chassis, and enclose the bottom with an appropriate off-the-shelf chassis, in time-honored VHF homebrew tradition.

With these building blocks, and reasonable care, any moderately experienced homebrewer can put together converters which will truly approach state-of-the-art performance. The only empirical fiddling which will be necessary will be that required to maximize the signal-to-noise ratio in the first tuned circuit. Right now, I should warn you that some of my tuned circuit values are computed, while others are proven in performance. They should be right on the money, but if you have to do a little trimming here and there to get things to peak up, don't be upset with me. A few hours spent working with these building block circuits will pay off in unexcelled VHF reception.

$15 T-POWER SUPPLY

Interest in amateur mobile communications has recently been stimulated with the increasing availability of retired commercial FM equipment. For many years the workhorse of the mobile power supply has been the mechanical vibrator. Semiconductors that are capable of handling the same task with increased efficiency and dependability are available commercially. All preliminary design goals were exceeded in operation of this solid state vibrator replacement.

The necessary prerequisites were:

- Simple design with low construction cost
- Minimal modification of existing equipment
- Operational dependability regardless of ambient temperature extremes
- Reduction of conventional T-power noise on transmitted signal

Although direct application is made to the General Electric 30 Watt Progress Line, with no circuit changes the same device may be used with comparable vibrator powered equipment.

Construction

The basic circuit is a two transistor push-pull inverter (Fig. 1).

Any toroid with a suitable feedback winding for the transistors in use and a secondary section capable of 250V at 70W may be used for (T1). (R1) the starting resistor will supply a minimum of 0.6V on the feedback winding centertap for a supply voltage of 12.6V. This will insure dependable transistor starting with the low ambient temperatures that are encountered in mobile operation.

The Motorola HEP 233 power transistor's maximum ratings include a 30% safety margin on the collector-to-base voltage (Vcb)

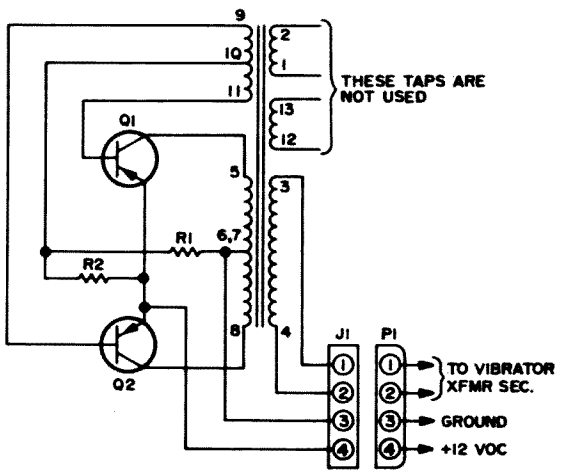

Fig. 1. Schematic diagram of T-power. R1 @ 200Ω, 10W; R2 = 10Ω, 10W; Q1, Q2 = Motorola HEP 233; T1 = Toroid T-2, $2.95 Tower Communications[1]; P1 = Cinch-Jones 4-terminal connector.

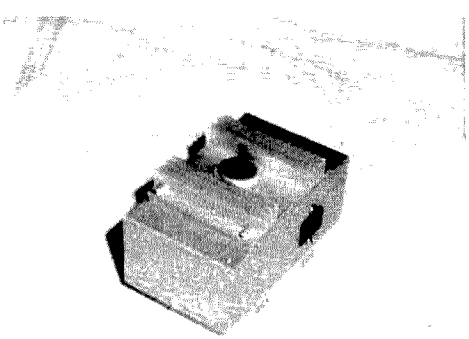
and collector current (IC) parameters. The HEP 231 power transistor may be used with increased savings in construction cost. However, this transistor should not be used in circuits requiring input power in excess of 70W. (Q1) and (Q2) are mounted on heatsinks and it is imperative that the TO-36 transistor case, the transistor's collector, be insulated from the chassis. A HEP 455 mounting kit provides insulation and maintains adequate heat transfer properties from the transistor to the heatsink.

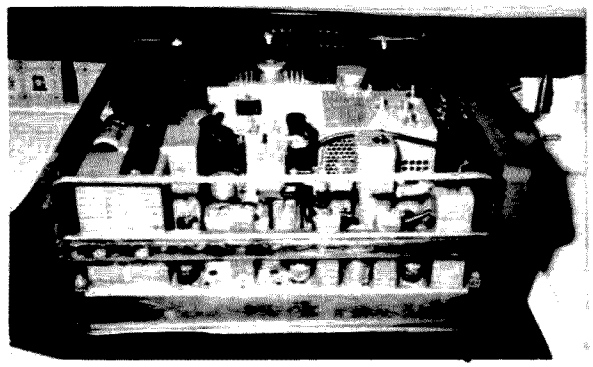
The heatsinks are mounted on a 5x3x2 in. aluminum minibox. A chassis mounted 4-conductor Cinch-Jones receptacle provides input power for the inverter and transfers output voltage from the toroid secondary to the mobile power supply. The toroid transformer and associated components are mounted within the minibox. Several drops of epoxy cement secure the toroid to the

[1] *Tower Communications, 1220--22 Villa St., Racine WI 53403.*



chassis. Any method may be used to secure the transformer provided the securing elements are of non-metallic composition. All connections to the individual transformer terminals are made with the assistance of a diagram supplied by Tower Communications with each purchase. Insulated 16-gage wire or larger is recommended for all connections.

Addition to Mobile Power Supply



An ohmmeter is used to test the vibrator equipment prior to attachment to the mobile supply. Resistance measurements across the 12V input terminals indicate a 10Ω forward and 50Ω reverse resistance. Under no-load conditions, the inverter output voltage is about 285V.

By connecting the inverter output to a selected secondary winding of the vibrator transformer, existing relay functions and rectifying components of the original mobile supply are used. The desired secondary winding is located by measuring the output voltage from combinations of secondary transformer taps while the receiver operates from the vibrator supply. The combination, which develops 250V under receive load conditions, will function as an input terminal for the inverter output. The (BLACK-RED) and (RED-GREEN) windings are used with the General Electric Progresss Line 30 Watt vibrator supply.

The 12V inverter input voltage is obtained from an appropriate terminal on the battery input socket. Terminals 4 and 1 at connector (J501) are used with the General Electric power supply. The inverter unit may be mounted on the front panel of the transceiver basket or on the power supply chassis. The final modification prior to operation is removal of the vibrator from its socket.

Top view of unit shows large heat dissipation area provided by heatsink.

T-power unit fits snugly between power transformer and relay on Progress Line power supply strip.

Summary

Installation of the T-powered vibrator replacement requires that the transmitter be retuned. Units using this power supply modification experience an input power increase of about 30%. Thus a heavy duty replacement for the final amplifier tube is recommended (i.e. 8298A or 6146W for the 6146A). Receiver B+ decreases about 10%. This slight loss extends the life of audio output tubes such as the 6AQ5 and does not impair receiver operation.

Examination of an unmodulated transmitter signal indicates little or no discernible audio distortion such as "T-power whine." The "whine" is filtered by choking action in the secondary winding of the vibrator transformer.

A significant improvement in the ambient noise figure of the receiver is noted with the T-power. Increased audio clarity on weak signal reception is very noticeable.

The T-power circuit described has been in use at my mobile station for over six months. Dependable service and improved equipment operation make this circuit a mandatory addition to any mobile installation.

EASY-TO-MAKE 1296 MHz MIXER yielding a 6.5 dB noise figure

Microwaves are for the birds. You have to go out of the way with equipment to accomplish what is eaqual to a 10¢ phone call. That is how I thought about it for years. But then I saw microwave walkie-talkies with built-in spiral antennas for Astronauts – that turned me on. Microwaves are great for space as you know. Low power communications are made over long distances and small physical antennas with high gain can be used. The future of these frequencies looks bright in every way. There are hams in the Arctic, airplanes, ships and soon I'll bet in space. And you cannot call for 10¢ to Mars. Besides, every ham cannot buy microwave equipment from the shelf.

So I needed a mixer to start with. The ones I had seen so far did not appeal to me. You could hang a diode on an antenna with a local oscillator and have a mixer, but it should be at its best. To be just that, you need the following:

1. Low noise microwave diodes
2. Good impedance match
3. Get the signal to the diodes and not into the oscillator circuit.
4. Get the local oscillator signal to the diodes and out of the antenna.

To accomplish these points I used:

1. Microwave Associates MA 4882 Schottky Barrier Diodes
2. L4, L5 are a bit shorter than a quarter

HAL COMMUNICATIONS
Box 365L, Urbana IL 61801 ● 217-359-7373

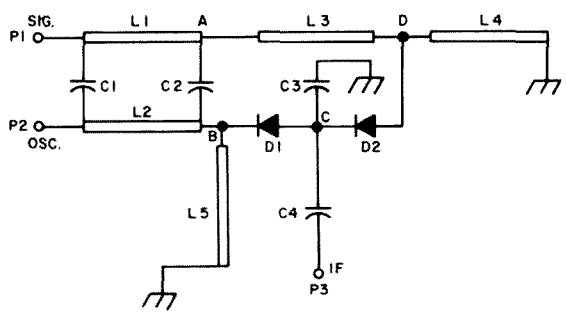

Fig. 1. Schematic. L1 – λ/8 50Ω micro strip line .176" wide, .755" long; L2 – λ/8 50Ω micro strip line, .176' wide, .755" long; L3 – λ/4 50Ω micro strip line .176" wide, 1.51" long: L4,5 – λ/4 micro strip line .050" wide 1.170" long; C1, C2 – 2.3 pF ± 0.1 pF Pellets 0.1" x 0.1"; D1, D2 – MA 4882 Microwave Associates; C3 15 – pF Pellet C4 – 100 pF. Dimension only good for a board with a dielectric constant of 2.5, two sides copper, 0.062" thick. The shape of L1, L2 is such that minimum coupling occurs. Capacitors from American Technical Ceramics, 1 Norden Lane, Huntington Station N.Y. 11746 were used. Order numbers are: C1, C2 – ATC 100 B2R3CP; C3 – ATC 100 B 150MP; C4 – ATC 100 B101MP.

wave, so besides the dc return path they are slightly capacitive to cancel out inductance

3. L1, L2, C1, C2 is a 3 dB 90° coupler. Power coming in Port 1 will be split between A and B with 90° phase difference. It is theoretically possible to have over 40 dB isolation between P1 and P2.

Through the λ/4 line of L3, 90° phase shift is added and any signal coming in will be split and 180° out of phase between D and B. So signal oscillator and dc should be balanced out at point C leaving only the difference at Port 3. C3 will ground any remaining signal and oscillator rf after mixing. C4 is a dc block for the i-f.

The coupler alone, (see Fig. 2) was made first to measure its performance. In the final mixer version it is hard to do that, especially after the diodes are in. They will multiply any signal and reflect these harmonics. Then I went to Fig. 3, soldered the components in and was surprised how well it worked. Watch for the distance of C1, C2 (see Fig. 3). As a substrate, double copper clad teflon fiberglass was used. To follow dimensions of Fig. 3 it must be 0.062" thick with a dielectric

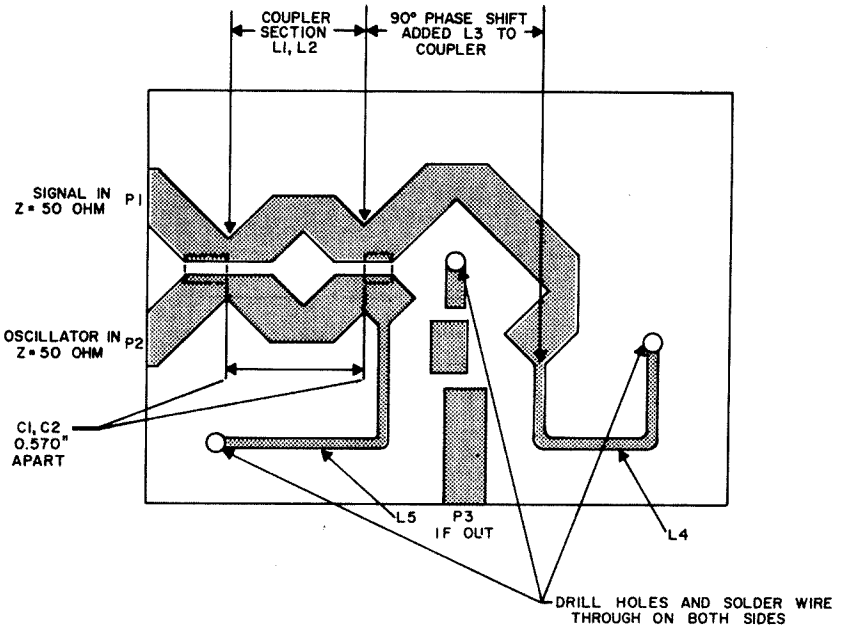

Fig. 3. Printed circuit board layout.

constant of 2.5, such as for teflon fiberglass. Photo etching would have been perfect, but not feasible, so both sides of the board were taped. The back side of the copper is needed as a ground plane. Then a drawing as in Fig. 3 was glued over it and cut out with a razor blade; the paper and tape where no copper should be was peeled off. After etching I drilled the three ground holes, stuck wire through and soldered it on both sides. As connectors I used OSM 244-3 with the mount soldered to the bottom foil.

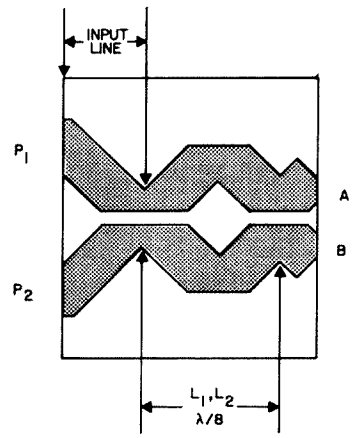

Fig. 2A. Board layout.

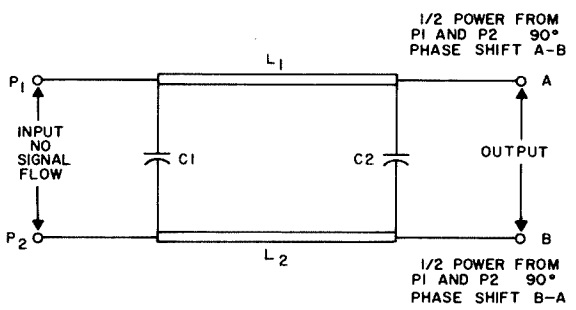

Fig. 2B. Schematic.

If you are not familiar with micro strip let's talk about it first, since the whole layout is based on it. It is similar to coaxial transmission line. Let's take L1, Fig. 2 – it consists of a .176" wide .755" long strip and a ground plane on the other side with a dielectric of 2.5 in between. The result is a $\lambda/8$ long 50Ω line. If it is made wider or the dielectric constant is higher the characteristic impedance will go down. Most of the electrical fields are contained between strip and gound plane. L1 and L2 are shaped in such a way that minimum coupling occurs.

Being fairly accurate with dimensions, this mixer should work very well. The lowest noise figure I got was with 2.8 mW local oscillator signal 60 MHz below 1296 MHz. An H-P noise meter with an i-f noise figure of 2.5 dB was used for the measurements, so that the actual mixer noise is even below 6.5 dB. Commercially available mixers with that noise figure will typically cost about $100.

I'd like to thank Raymond Camisa and Wheeler Laboratories for helping me complete the mixer. . . .WB2YVY

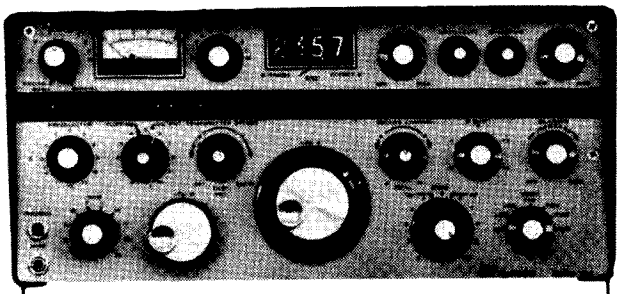
VHF REPEATERS IN EUROPE

A status report with some vacation planning tips.

The rapid growth of repeaters in Europe and the fact that temporary operating licenses can be obtained by U.S. amateurs in many European countries opens the way for the U S. amateur visiting Europe to enjoy VHF FM operation. The advantages of such operation as compared to carrying along HF gear are many. First of all, the equipment itself that is required is relatively simple. Any number of the commercially available or home-built transceivers that are battery operated and deliver 1–2 watts output will fit in a suitcase and will suffice for most repeater operation. Antenna requirements are simple and a simple whip antenna can be used or a portable beam be made of wire elements for indoor use which also will easily slip into a suitcase. But, the greatest advantage of VHF FM operation in Europe is probably the contact that it allows with local amateurs. As in the U.S., the operators that use most repeaters in any given city pretty well get to know each other through repeated QSO's and the QSO's tend to get somewhat "stale" at times. A new station and particularly one speaking English and using a special temporary call sign will usually find a special welcome on a repeater channel that is far more pleasant than that experienced on HF (more on operating habits and courtesy later). Last, but not least, one may be able to operate 2 meter FM in Europe although one has less than a General Class license and therefore could normally not secure a reciprocal license.



Licensing

The material in this article is mainly directed at the amateur visiting Germany, Austria or Switzerland since the repeater possibilities are the most developed in these countries. All repeaters in these countries are also available to any amateur to use (private repeaters are basically not allowed). Germany, particularly, has a large and developing repeater network throughout the country. Many other countries plan repeater networks, such as England, but do not have repeaters yet in operation because of technical approval and details that remain unresolved with their administrations. The latter is unfortunate for the visitor since 2 meters as such is a popular band in England and a number of beacon transmitters are in operation. As a matter of interest, there are some 60 VHF beacons operating in Europe in-

the **Incomparable**

CX7A

by signal/one

Features:

- RELIABILITY IS NOW standard equipment. Every CX7A "burnt-in" and cycled more than 48 hours.
- QUALITY-PLUS. Every component is instrument grade. American-made, and individually tested.
- ALL MODES 10 thru 160 meters in full 1 MHZ bands with overlaps.
- BROAD-BAND TUNING. Instant band changes without tuning.
- TRUE BREAK-IN CW with T/R switching.
- IF SHIFT – deluxe QRM slicer.
- PRE-IF NOISE-BLANKER that really works.
- RF ENVELOPE CLIPPING – sounds like a Kw.
- TWO VFO'S Transceiver Plus receiver.
- BUILT-IN: Spotter, FSK shift, transmit offset, wattmeter, SWR meter, electronic CW Keyer.

Specifications:

- SENSITIVITY: Better than 10db signal-plus-noise-to-ratio for .25 microvolts at 28 MHZ.
- SELECTIVITY: 2.4 KHZ @–6db, 1.8:1 (6:60db) shape factor. (16 pole crystal lattice Filters) optional:
- CW-300 and 400 HZ. FSK-1200 HZ.
- CARRIER and unwanted sideband suppression. Minimum 60db.
- IMAGE and IF REJECTION: more than 60db.
- POWER LEVEL: 300 to 500 watts p.e.p. plus, continuous duty cycle.
- POWER AMPLIFIER: 8072 final completely broad-banded driver and final. 150 watts continuous dissipation rating.

It's Perfection for $2195

If you want to move up to the BEST, give Don Payne, K4ID, a call for personalized service, a brochure, and a KING-SIZE trade-in on any gear you have - one piece - or the whole station.

cluding 40 on the 2 meter band and 11 on the 432 MHz band. However, before any operation can be undertaken one must, of course, secure the necessary temporary operating license on the basis of one's U.S. operators license. Given below are the addresses to write to in order to secure the necessary application forms. A photostat of one's U S. license is required and a small fee of a few dollars. Be sure to fill out the application form as directed and also to take care of the licensing arrangements a few months ahead of time. In most cases the amateurs who handle the details of securing the reciprocal licenses from the necessary authorities in their countries do so on a volunteer basis and one should attempt to help them as much as possible. Try to remit the necessary fees in the amount required in their currency rather than sending a simple personal dollar check which requires that they go through an extra effort to have the currency converted. The service that is provided is usually very fast and efficient. For instance, the last time I applied for a temporary license in Germany, it took only about 2 weeks to complete the whole transaction. A license was received authenticated by the necessary Post Department authorities (a branch of the Post Office Department acts as the equivalent of the FCC in almost all European countries) and it was complete with a detailed booklet, in English, which explained the operating regulations, power limits, etc. Be sure to indicate that operation only on VHF will be undertaken if one has only a Novice or Technician Class license.

Equipment to Use

This section covers the frequency channels in use but a word about the FM equipment in use in Europe might first be in order. In general, one will find that 2 meter FM has generally gone down the same equipment development phases in Europe as in the U.S. Much of the initial 2 meter FM work, particularly mobile, was done using FM equipment converted from commercial surplus. Instead of names like Motorola or GE, many amateurs will report that they are using Siemens, Telefunken or Storno equipment. The power levels in use tend to be somewhat lower than in the U.S. with mobile installations rarely exceeding the 25 watt output level. Repeater installations also tend to be low-powered and often the Postal authorities limit the repeater power levels to 15 watts output. Today, the amateur sales market in Europe is in full bloom with Japanese made equipment. Almost all of the brands sold in the States (and some not yet sold in the States) are available, although sometimes under different brand names depending upon which company has picked up the distribution rights from the original Japanese manufacturer. For instance, the Drake TR-22 is sold under the original manufacturer's name as the Trio TR-2200. The Tempo line is sold under the Yaesu or Sommerkamp labels, etc. But the imported equipment is basically the same as that sold in the mp labels, etc. But the imported equipment is basically the same as that sold in the U.S. although it may be a bit confusing at first when one describes his station in a QSO and finds that in spite of different names, the equipment is the same.

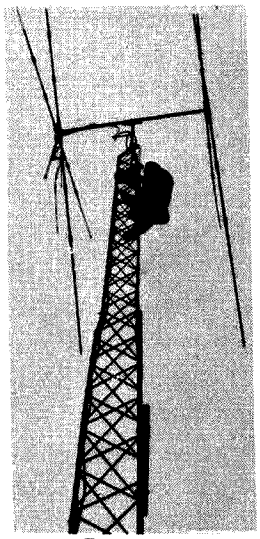
A price comparison for imported equipment of a similar nature in Europe and the U.S. is difficult because of the accessory items that are sold in some cases as part of the equipment and in other cases as extras. German distributors tend to market the Japanese equipment exactly as it is packaged for use on the Japanese market. That is, with a few standard Japanese channel crystals installed (useless in both Europe and the U.S.) and with the original Japanese equipment manual perhaps supplemented by a very brief translation of the most important circuit features. For this reason, one may find Japanese equipment costing a few dollars less in Europe, but the difference is not significant.[1]

Nonetheless, one may want to consider purchasing some VHF equipment in Europe. There are the advantages that one doesn't have to worry about transporting the equipment and going through customs. The equipment can also be ordered with crystals installed and tuned up for use on the main European repeater channels. One may also be able to work out a purchase-repurchase arrangement with an equipment dealer, since the FM equipment market is strong for both new and used gear, so one would in effect be renting the gear. One would have to work out these arrangements on an individual basis. The place to start would be to write for a brochure on the VHF FM equipment available to some of the larger dealers in amateur equipment, such as:

Hannes Bauer Company
P.O. Box 2387
Bamberg, Germany

or

Richter Company
Grabben Strasse 9
Hannover, Germany



Both of these companies also provide full-size catalogs of all of their amateur gear, but the cost of each catalog is $2.50.

Tone signaling is not yet used on most repeaters, except in Switzerland. If it is used (indicated in next section), a standard tone frequency of 1750 Hz is used. Only one or two repeaters, such as the Berlin one, use complicated entry signals which generally would not be useful for the visiting amateur to provide for. The definite trend on 2 meters is towards repeater entry via a 1750 Hz tone, although for the next year or so

[1]These radios are often redesigned in order to meet FCC specifications for emission. Tests at the 73 labs have confirmed that the difference is substantial – Ed.

one will be able to use most repeaters without any tone entry. If one already has a tone generator built into a 2 meter FM transceiver, it would be a good idea to reset it for 1750 Hz if its present frequency is much more than 50 Hz removed from this frequency.

Repeater Channels in Use

The installation of repeaters in Europe is growing rapidly and in some countries, particularly Germany, one can find a repeater to enter from practically any corner of the country. This rapid growth of repeaters has brought with it the usual problems of channel spacing and overlaps in coverage so repeater frequencies are subject to change. Nonetheless, the repeater frequencies shown here should certainly be useful throughout 1972.

As one reviews and studies the development of 2 meter FM repeater installations in various countries of the world, a rather sad picture emerges about amateur radio. Repeater channels in most countries were chosen on the basis of the channel spacings common for commercial surplus FM equipment. But for a hobby that is supposed to be as "international" as amateur radio and with all the international cooperation that is supposed to exist among the amateur organizations, one would think that as 2 meter FM enters its second generation that some order would be agreed upon for at least the main repeater frequencies. Instead, if one looks at the Japanese FM channels, the U.S. channels and the European channels, they are all different and what is perhaps worse, the planning that goes on for future repeater channels will keep them all different. Even the so-called "calling frequencies" in each country are different. This is all in spite of the fact that aside from some small exceptions, the first 2 MHz of the 2 meter band is designated for amateur usage in Regions I, II and III of the world by the ITU.

Germany

Germany has two major calling frequencies designated. One is 145.000 MHz and the other 145.150 MHz. Unfortunately, the latter frequency corresponds to one of the repeater frequencies and if one wanted to

equip a transceiver for a simplex channel, 145.000 MHz would be the better and more common choice. However, a calling frequency channel is not necessary and for a low-powered transceiver may prove fairly useless. After all, if one is using a 1 watt transceiver with a simple whip antenna only slightly above ground level or in a city hotel room, one might as well walk the short distance covered via a direct channel.

Repeaters cannot be freely put into operation in Germany and a great effort has been made to develop an overall frequency plan for repeaters. Basically, a special permit is required from the German equivalent of the FCC to erect a repeater and this permit will not be granted unless the German Amateur Radio Club (equivalent of ARRL) first approves the repeater proposal as being compatible within the existing system. Repeaters can have a maximum power output of 15 watts and a deviation of ±5 kHz. Vertical polarization is used and the repeater identifies itself at least every ten minutes by F2. At the present time, a tone signal is not used to open most repeaters, but the definite trend is to use a 1750 Hz tone to open the repeater. At the moment, there are four repeater channels designated:

Channel	Transmit to Enter	Receive On
1	144.150	145.750
2	144.200	145.800
3	144.250	145.850
4	144.300	145.700

These channels with 50 kHz spacing were arranged on the basis of the 50 kHz channel spacing formerly used by commercial FM gear. A plan has been started by the German Radio Club to convert to 25 kHz channel spacing and to create 3 more standard repeater channel. If one is planning on visiting specific cities, one can search out the channels necessary. For general travel, it is obvious that equipping a transceiver for the new channels 2, 4 and 6 will provide the broadest coverage. There are two repeaters that operate on non-standard frequencies, probably because of their partial coverage into East Germany so East German stations can also be contacted. One is the Berlin repeater DLØSB (transmit on 145.150, receive on 145.600). A tone sending the number 6 opens the relay. The other is the Elm mountain repeater (transmit on 144.800, receive on 145.900). The following are the standard channels and repeater locations in Germany:

Channel	Transmit to Enter	Receive On
2	144.150	145.750
3	144.175	145.775
4	144.200	145.800
5	144.225	145.825
6	144.250	145.850
7	144.275	145.725
8	144.300	145.700

Austria

Austria has generally followed the same philosophy in developing a 2 meter repeater network as in Germany. The Austrian system is not as yet developed as the German one but progress is being made. Many Austrian amateurs who live near the German borders using the German repeaters, along with the relatively low amateur population may account for the lack of development of a repeater network in Austria. The channels used in Austria are the same as those used in Germany so refer to the German channel frequency listing for the following Austrian repeaters:

Channel	Call Sign	Location
1	OE5XGL	Altmuenster
2	OE5XUL	St. Johann
2	OE7XTI	Innsbruck

The above repeaters are in operation presently. In addition two other repeaters, one in the OE3 and one in the OE6 sector of Austria, should be in operation later in the year. No details are available on these latter repeaters as yet but they will most likely use the same channel as the above repeaters.

Switzerland

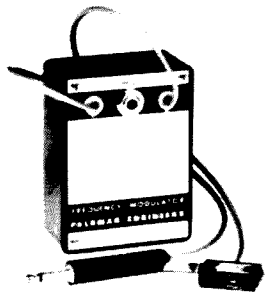
2 meter repeaters are not allowed by the postal authorities in Switzerland but they are allowed in the 432 MHz band. Amateurs there have therefore turned to developing a network of 432 MHz repeaters. Two standard channels are used:

Channel	Transmit to Enter	Receive On
1	431.050	438.920
2	431.200	438.800

The repeaters in use are:

Channel	Canton	Entry Tone Frequency
1	Zuerich	1160 Hz
1	Luzern	1595
1	Fribourg	1290
2	Luzern	1160
2	Solothurn	1160
2	Appenzell	1595

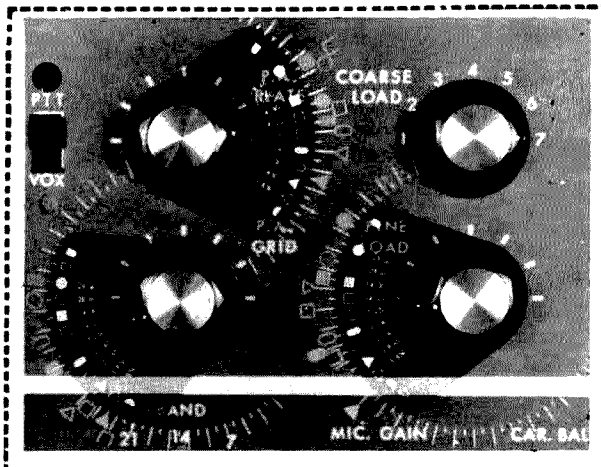
The tone call is necessary to open the repeaters. The repeater frequencies are compatible with the 432 MHz repeaters in Germany although there are only two such/latter repeaters in use, one in Frankfurt using channel 1 and one in Giessen using channel 2.



Operating Habits

As was mentioned before, foreigners will find a nice welcome on VHF FM but the way to start is not by breaking up a QSO that is taking place. Take the time to listen first to see what the operating practices are like. Most amateurs will try to keep their QSO's over repeaters relatively short and will particularly try to give preference to mobile stations calling in. Even in spite of the language problem, it is relatively easy to learn to recognize when the repeater is free. Then a short QRZ in English can be called. Often, one will fine many stations eager to have a QSO in English and perhaps sometimes too many. If one finds too many stations lining up for a QSO it would be a good idea to go QRT for a while rather than monopolize the repeater. After all, it is their repeater. Most stations will be glad to exchange QSL cards if desired although one sometimes hears the comment that repeater QSO's aren't really direct QSO's and therefore don't deserve QSL's. Phone-patching is not done so don't bother to ask for it.

Antennas



Taking a small transceiver along on a vacation trip can generate some antenna problems. A simple whip antenna such as that built into some transceivers will work fine in a good high QTH but normally supplementing it with a better antenna will prove worthwhile. One of the simplest antennas to use is a folded dipole cut to frequency much like an indoor FM dipole. A small balun of the type used for broadband FM-TB 300 Ω to 75Ω conversion will handle 1 – 2 watts and can be mounted at the transceiver so twinlead can be used to the folded dipole which is also constructed from twinlead. The advantage to this type of antenna is that it can be moved around in a room for the best results while the transceiver remains stationary. The antenna can be fastened to a window with tape. The dimensions for such an antenna for 2 meters are shown in Fig. 1A. If one wants to get just a bit more elaborate, a portable beam can be constructed using the rods formed from metal clothes hangers and a few banana jacks and plugs. By choosing the antenna

FM YOUR GONSET COMMUNICATOR

- New! Plug-in modulator puts the Communicator transmitter on FM.
- No modification or rewiring on your Communicator. Just plug into mike jack and crystal socket.
- Compact self-contained modulator measures 4" x 3" x 1½".
- Works with Communicator I, II, III, IV and GC-105.
- FM at a tenth the cost of a new rig.
- Frequency adjust for netting built in.
- Built-in tone burst available. Keyed by push-to-talk switch.
- $34.50 postpaid U.S.A. Built-in tone burst $10.00. Specify Communicator model and tone-burst frequency. California residents add 5% sales tax. (HC-6/U crystal and 9 volt transistor battery not supplied.)
- Send for free descriptive brochure.

BOX 455, ESCONDIDO, CA 92025

PRECISE INSTANT TUNING (PIT) KITS for Swan 350, 500/c/cx are now available and soon PIT Kits will be ready for other manufacturers' models. Kit consists of knobs assembled to skirts with frequency identifying numbers and geometric symbols, panel plate, templates and white pencil for drawing frequency symbols on panel plate to correspond with symbols on dial skirts. Kit can be installed in 15 minutes. After your initial optimal tuning and frequency identification with symbols on panel plate, you can quickly change bands and accomplish accurate retuning simply by rematching the symbols identifying the fine graduations on large dial skirts and panel plate. No more troublesome on-the-air tuning with time loss and QRM, just change frequencies, match symbols and start transmitting!

SATISFACTION GUARANTEED.

PIT Kit (specify your equipment model) complete with knobs assembled 11.87*
PIT Kit without knobs (skirts with adhesive for assembly of your knobs) 9.96*
*Add 35¢ for handling and mailing in U.S., Poss. & Canada. Elsewhere add 55¢. Calif. res. add 5% sales tax.

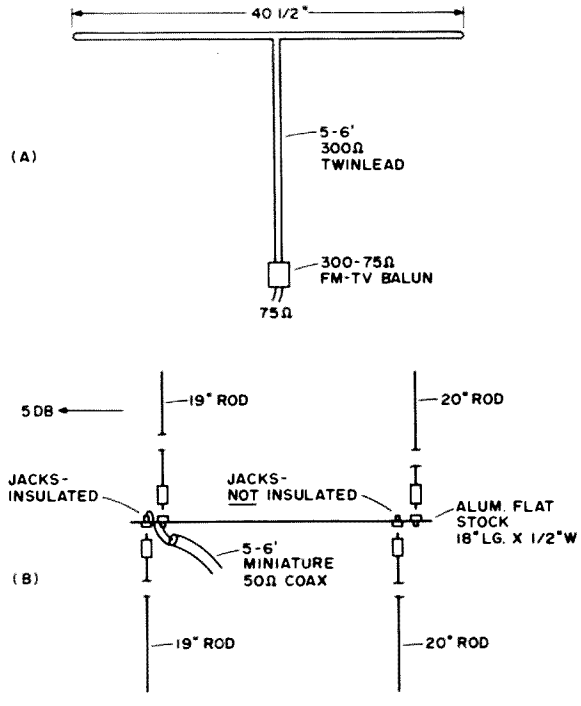

Fig. 1. Two simple antennas for 2 meters.

dimensions properly, as shown in Fig. 1B, the driven element will directly match a coaxial cable feed. The whole antenna just plugs together in a matter of seconds and can be easily transported. In use it can be supported from a piece of furniture, taped on a window, etc. The 5 dB of gain provided will easily make the difference at times between being able to activate a repeater and not being able to do so, as I have often experienced when using a TR-22 and the antenna inside a room. Use miniature coaxial cable to feed the antenna such as RG174 or RG178. The difference in attenuation between these cables and RG58 or RG59 for lengths of 5 - 6 feet at 2 meters is not significant and the miniature cables can be handled conveniently like hook-up wire.

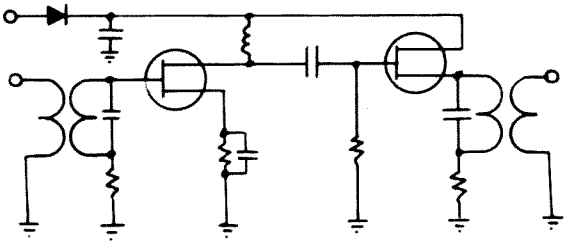
LOW COST THICK FILM RF PREAMP

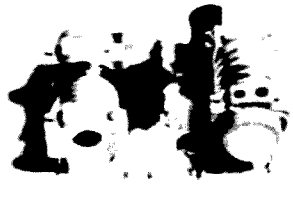
This article presents a low cost rf preamplifier most economically expressed in thick film technology. Input and output impedances are 50Ω to match conventional transmission lines. The tuned circuits are preset during manufacture but may be repeaked when the preamp is installed. The entire unit is injection molded to produce a waterproof, virtually indestructible product.



The basic preamp circuit may be referred to as a "handbook circuit." It consists of a 2N5245 N channel FET as the rf amplifier with a second 2N5245 as a source-follower. The purpose of the source-follower is to isolate the rf amplifier from the remainder of the receiver circuitry and thus prevent oscillation. Chip resistors and capacitors have been utilized with discrete transistors. Later improvements will include chip semiconductors.

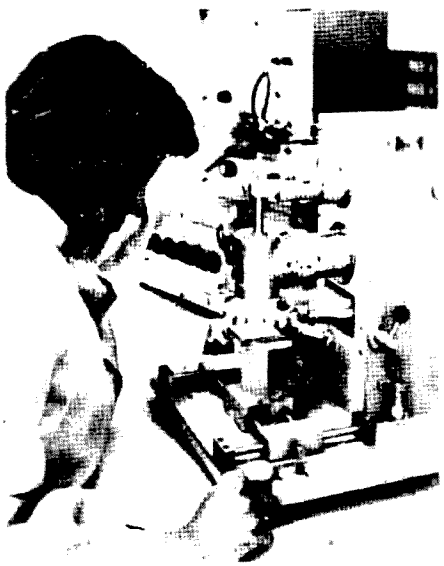
The original design utilized fixed inductance and close tolerance NPO capacitors. However, this method was not conducive to high volume production. Also, such a system allowed no compensation for outside circuit parameters. Thus, the revised design incorporates slug tuned coils.

It was originally planned to make the unit field serviceable. However, most field service stations are not equipped to handle hybrid circuit repairs. Also, the low initial cost of the hybrid circuit makes replacement rather than repair more economical. The final design consists of an injection molded package with provisions for alignment of the slug tuned coils. The rf input, rf output and power cables are all internally connected before molding. The injection molding produces a waterproof, virtually physically indestructible package.



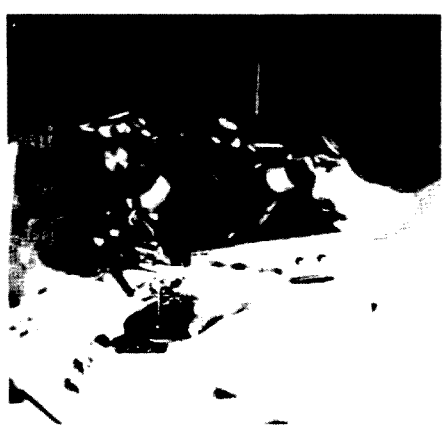
Protective Circuitry

The amount of protective circuitry depends upon the application. All units incorporate reverse polarity protection in the



1. Basic Schematic

Fig. 1. Basic schematic.



Interior view of preamp.

form of a silicon diode (1N4001). In applications involving medium and high power transmitters in close proximity to the preamp, germanium diodes are placed across the input to protect the field effect transistors. In low power applications such as CB where power output is restricted to 3.5W or less, the diode protection of the FET's is not needed. For special applications, the entire circuit may be shielded.

Assembly operations.

Applications

The hybrid preamp was originally designed for use in CB equipment (27 MHz). The original application is as an "add-on" accessory to the receiver portion of the unit. Other applications include incorporation of the hybrid circuit as the receiver "front end" in new design equipment and in receivers for radio controlled equipment.

This hybrid concept may be expanded to include thick film rf preamps for other services. These include low band FM (25–50 MHz), 6 meter amateur (50–54 MHz), special single channel television requirements (54–88 MHz and 172–220 MHz), FM broadcast (88–108 MHz), aircraft (108–132 MHz), high band FM and 2m amateur (132–172 MHz). Other possibilities include UHF FM communications (450–470 MHz), industrial radio control (72-76 MHz), and other VHF and UHF radio services.

Fabrication area.

Construction

The construction begins with a 0.015 in. ceramic substrate. On this is screened a paladium-gold conductor pattern. The substrate is then fired at 900C. After firing, the substrate is inspected and passed to the assembly department. Assembly begins with the soldering of the chip components, progresses through mounting of the discrete active components, and finally to the mounting of the rf coils and external connection leads. The unit is then visually inspected.

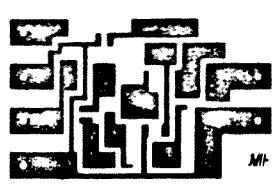


Fig. 2. Substrate conductor pattern.

FORT WORTH, TEXAS 76110

Initial Testing

After completion of assembly, the unit is given an initial electrical test and rf alignment. This stage consists of the application of the required 12V dc to the unit and checking for dc parameters including excessive current and open circuits. The initial rf alignment is as follows: A signal at the desired frequency is applied to the input of the hybrid circuit through a 50Ω pad. The output of the hybrid is connected through a second 50Ω pad to an indicator. Power is then applied and the slug tuned coils peaked. The total gain of the preamp is measured and if within specifications, it proceeds to the next stage, encapsulation. If the hybrid circuit fails, it is sent to a repair station for troubleshooting. After repair it again is visually inspected and undergoes a second complete electrical and rf test.

Encapsulation

The final manufacturing stage consists of encapsulating the entire circuit through injection molding techniques. Teflon rods are inserted into the slug tuned coils to form holes in the encapsulation material to allow alignment after the unit is installed. After encapsulation, only the three cables (rf in, rf out, and power) and the holes for alignment are visible.

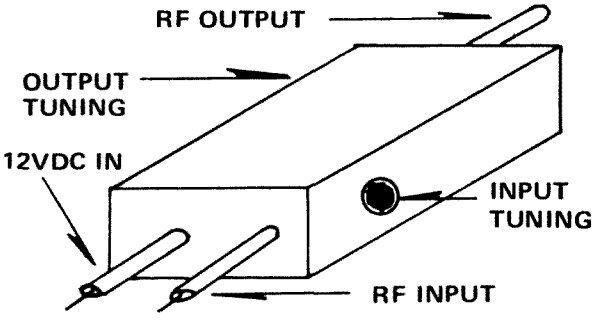

Fig. 3. Final package.

Final Testing

After encapsulation the unit is given a final electrical and rf test. Because of the encapsulation material, it is necessary to slightly realign the tuned circuits. If the unit is rejected, it must be discarded. Accepted units are labeled and serially numbered.

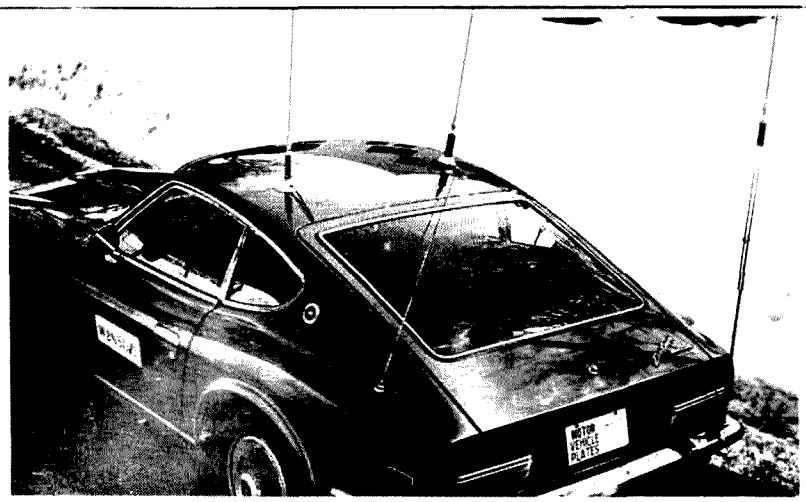
PICTURE PAGE

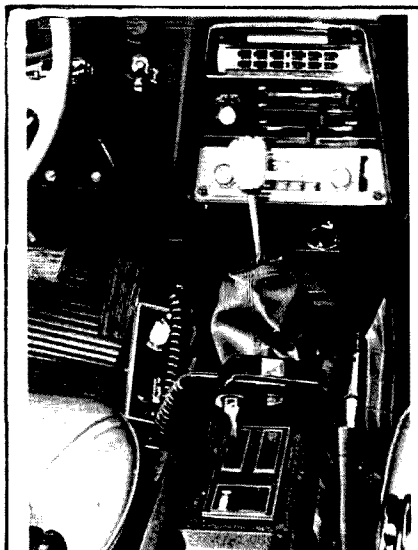
ABOUT 8,000,000 CONTEST POINTS



On a recent visit to Washington Wayne visited the Potomac Valley Radio Club and snapped this candid picture. These are the big guns of the east coast — they were adding up their cumulative score for the DX contest and it staggered the mind. Was it 8 million, 12 million or 15 million points? Whatever it was, they sure must have beat out their perennial rivals up in Philadelphia. This group has worked everything there is to work — they must be very happy.

WHICH ANTENNA WORKS BEST?

The gain figures used in advertising can sometimes be confusing. Here is the W2NSD/1 Datsun 24Z with two magnetic mount 5/8 wave whips and a bumper mount 5/8 wave. Some bad things have been said about the magnetic mounts so we decided to check it out and see what difference there was between them and a substantial bumper mounted antenna.



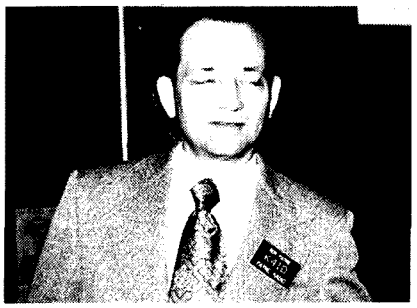
You can't just switch from one antenna to another because the "picket fence" phenomenon causes the signals to go up and down by several S-units every time you move a few inches. This means we had to drive around and try to find average figures — peak figures — etc. After a lot of driving and antenna switching, there was little doubt as to which antenna worked far better than the others — none of them. We could not really see any significant difference and that is a fact.

The extra antennas have been removed and the car now looks a little less like a moulting porcupine.

Jean Shepherd K2ORS, at the recent FM Symposium run by 73 Magazine, talks from one table to another over the din using an rf boost. After the dinner Shep gave a performance which resulted in laughing fits for a good part of the audience — three hernias and one double hernia. Two representatives of a national amateur organization were there — one smiled — briefly.

SHEP PR DEPT.

Jean Sheperd's America will be back on PBS television starting July 6th at 8PM on Thursdays. Don't miss this interesting series by one of our old time amateurs K2ORS. It won't hurt to drop a letter to your local PBS station telling them that you want to see this series — they are very responsive to such letters.



MOUNTING THE RIG

What do you do when you succumb to buying a car which turns out not to have any reasonable place under the dash to mount the FM rig? Here is the cockpit of the Datsun 240Z which has one of those molded paperboard dashboards with just no place to hang a rig.

The bracket for the 826 was mounted on the transmission hump and the rig slides into place easily. It takes but a minute to remove it for crystal changes and it is out of the way of the leg. There is room for a second 826 on the right hand side of the hump, if you need to go for 24 channels in your area and have the loot. The power amplifier — TPL — 120 watts — is under the seat — also out of the way.

The next step is a touchtone pad and tone burst unit which will go in place of the pencils on top of the hump. The hand mike will eventually be replaced by one fastened to the sun visor and a push-on push-off switch will operate the rig — thus making driving a little safer. Even as handy as the mike is, it would be better not to have to use one hand for it.

AT DAYTON

Don Payne K4ID. Perhaps you've noticed the growing ads in 73 by Payne Radio. Don has been bringing the Signal One transceiver to the attention of amateurs through his ads. . .and selling this incrediple new unit.

Fred Deeg K6AEH, president of the Palisades Amateur Radio Club (last we heard) and sales manager of Standard Communications. Fred is an avid two meter FMer and has had a lot to do with the most used Los Angeles repeater, the PARC WA6ZDI station. Fred is deeply involved with the soon-to-be-announced Standard repeater package

Tom Litty K6RAD shows his new 220 transceiver (marketed under the Tempo name by Henry, but made by TPL Communications in Hawthorne, California). This unit is both an FM crystal controlled transceiver and an AM tunable receiver with transmitter vfo! The price is expected to be in the neighborhood of $220, which is sure to be a very popular neighborhood. Looking on are Gene Hastings W1VRK and Eli Nannis W1HKG, the two powers behind the Boston and Swampscott conventions.

AMSAT NEWS

Michael Frye WB8LBP
640 Deauville Dr.
Dayton OH 45429

Receiving A O-C Signals

Very soon, AMSAT in cooperation with NASA will launch its sixth satellite, AMSAT–OSCAR–C. A-O-C will be a real step ahead for amateur radio. It will enable hams from all over the world to participate in some of the rarest DX ever.

Most hams are already aware of this. However, very few still understand completely how to get the most use out of A-O-C. The first thing the average ham asks is, "What type of equipment do I need," and "where do I aim my antenna" etc. This column is designed to give the straight details plus a little help to the person just starting.

Transmitter

The first step is putting out a good signal on two meters. The satellite receives signals between 145.9 MHz and 146.0 MHz. It will accept any mode appearing within this band and repeat it. CW or SSB are recommended because they utilize A-O-C in the most efficient way. As far as power goes, 100 W of effective radiated power (erp) is just right. Any signal stronger than that will overload the receiver or increase the gain, thus reducing A-O-C sensitivity.

Finding such a transmitter, if you do not already have one, is not really as hard as it sounds. First if you are a do-it-yourselfer, you can assemble a neat little rig that puts out about ten watts on two meters, then use a 10 dB antenna to bring the signal up to full strength. Second you could convert any of a number of surplus 2m rigs to CW by keying the carrier. In other words, this does not have to be an expensive endeavor.

Dave Ingram K4TWF, who writes the SSTV news in 73. Dave is one of the more prolific writers on the subject and has been responsible for a good deal of the interest that has grown in this fascinating new aspect of amateur radio.

Receiving

Most good amateur receivers capable of receiving 29.45 MHz will be fine for receiving signals from A-O-C. Receiver sensitivity and selectivity should be fairly good; however, since there is a high level of man-made and galactic noise on ten meters an extremely good front end is not required.

Antennas

The antenna that you use will probably be the most critical item you will need. Because it will determine the effectiveness of your station, the ten meter receiving antenna is the most important. Some form of directive array is recommended. A height of 50 feet off the ground is probably the all around best. Antennas mounted higher, thus having a low angle of radiation, will be best for DX work since the satellite will be near your horizon. For local contacts the lower antenna will pay off because of its high take-off angle.

For the 2 meter antenna a simple dipole will do, or a directive array depending on the transmitter's erp. If a beam is used it has to be aimed in the general direction of the satellite. A good idea is to mount it at a fixed elevation angle of 30°, since this will afford the broadest take-off angle. Again for the DX hunter the antenna should be mounted normally since this will aim the boom at the horizon for low angle shots.

Since A-O-C will last for about a year, this column will continue to inform on techniques and latest happenings in the mission. For all those interested in receiving additional data such as an A-O-C telemetry chart individual system explanations, and command functions. Please send SASE to me and I will send you a free copy.

FLASH!

Just before press time, we learned that A-O-C will not be launched in July as scheduled. The new launch date is still unclear, but it is expected to be in the late fall or early winter. Keep reading *73* for details of all OSCAR flights.

The South Milwaukee Amateur Radio Club will hold its third annual Southeastern Wisconsin SWAP-FEST on July 15th at Shephard Park (American Legion Post 434), 9327 So. Shephard Ave., Oak Creek, Wisconsin. The activities will start at 7:00 A.M. and run until 5:00 or later. There is plenty of parking and a picnic area. Admission is $1.00 per person. Bring your friends and whatever goodies you have to swap or sell. For more information write to A.R.S. WB9EQA, William N. LeCourt, 1900 West Kimberly Ave., Milwaukee, Wisconsin 53221.

* * *

Model Rocketeers will hold an on-the-air convention on July 15 at 1800 GMT on 3,992 and 14,300 - each give or take a little. The Ludlow (MA) Amateur Radio Club is sponsoring the convention, and net control will be WA1NIC.

TWO RIVERS HAMFEST

The Two Rivers Amateur Radio Club of McKeesport will hold its annual Hamfest on July 16, 1972, at the Clairton Sportmans Club off Rt 51, near Pittsburgh, Pa. For flier write WA3MWM C. Thomas, 7022 Blackhawk, Pittsburgh PA 15218.

* * *

The annual Indiana Radio Club Council Picnic and Hamfest will be held on July 9 at the Lafayette Fairgrounds. There will be a flea-market for the hams and fun and games for the rest of the family. Trailer parking is available. Indiana's Ham-of-the-Year award as well as other operating awards will be made. Tickets are available from any IRCC club, or by mail, or at the gate. Advance tickets are $1.50 each by mail from W9YIP, 477 Robinson, West Lafayette, Ind. Orders should be mailed by July 4. Enclose payment and SASE. Tickets at the gate will be $2.00. There will be advanced and grand prizes as well as other prizes.

* * *

The Annual Wyoming Hamfest will be held July 15th and 16th 1972 at the Holiday Inn, Thermopolis, Wyoming. There will be prizes, a banquet Saturday night, Swapfest, Technical talks, Ragchews, Representatives from MARS, etc. Talkin on 3920 and 2 meters. Golfing, swimming and picture taking of the buffalo that roam at will in the State Park. The Hamfest is sponsored by Mildred and Joe Ernst of Thermopolis.

* * *

ONTARS, the Ontario Amateur Radio Service, sponsored by R.S.O. Inc., operates daily, all year, from 7AM to 6PM local time on or about 3775 KHz. It is a public service net for the express purpose of handling traffic, but check-ins from stations without traffic are most welcome.

A cordial invitation is extended to our American amateur friends to avail themselves of this service. ONTARS net control will recognize check-ins from all modes - SSB, AM and CW. For US amateurs operating mobile in Ontario this is an easy way to obtain traffic information, directions, etc. and meet new friends.

ONTARS will be looking for those W and K calls.

* * *

The first annual picnic of the Northwest Amateur Monitoring Service (NAMS) will be held Sunday, 16 July 1972 at Lewis & Clark State Park about 10 miles south of Chehalis, Washington, on old Highway 99.

NAMS will be one year and one day old on the day of the picnic. Overnight camping is available at Lewis & Clark State Park, with 40 spaces available. Bring wood for campfires, and bring food - it's a pot luck picnic, begins at 1 PM.

1972 County Hunters Contest July 29–30, 1972

The CW County Hunters Net invites all amateurs to participate in the 1972 CW County Hunters Contest. All mobile and portable operation in less active counties is welcomed and encouraged.

Contest period: 0000 GMT July 29 to 2400 GMT July 30.

General Call: CQ CH: Exchange - QSO number, Category (portable or mobile), RST, State (province or country) and county (U.S. stations). Scoring: QSO's with fixed stations are 1 point, QSO's with portable or mobile stations are 3 points. Multiply the number of QSO points times the number of U.S. counties worked.

Logs must show category, date/time in GMT, station worked, exchanges, band, QSO points, location and claimed score. All entries with 100 or more QSO's MUST include a check sheet of counties worked or be disqualified. Logs must be postmarked by Sept. 1, 1972 and sent to CW County Hunters Net c/o James E. Hoffman K1ZFQ 42 Gresham St., Milford CT 06460.

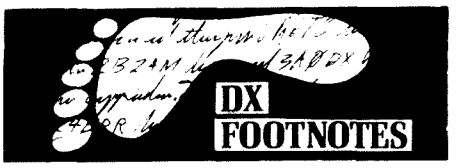
* * *

The Dade County Amateur Radio Public Service Corps will operate Special Events Stations from the National Political Conventions, Miami Beach, Florida during July and August. Tentative planning: Formal traffic Schedules and traffic nets. Contact frequencies 7072 14072 CW, 7272 14317 SSB. Station hours - 10:00 AM - 10:00 PM EDT, 1400Z - 0200Z. Calls/Dates - WD4USA, Democratic, July 10-13, WR4USA, Republican, August 21-24. QSL Info (SASE) to: Special Event Station (call), PO Box 501, Miami Springs, FL 33166.

* * *

The Quebec's amateur radio association, R.A.Q.I., will be holding its annual convention at the Cite des Jeunes in Vaudreuil Que. on June the 30th, 1st and 2nd of July. All amateurs of course are welcome and we will have french and english talks on technical subjects. Also, door prizes will be given during the convention, including 2 main prizes which will be awarded at Sundays's banquet.

* * *



The largest meeting of radio and electronic enthusiasts in the midwest is scheduled for Radio Expo '72 at the Lake County Illinois Fairgrounds on July 8 & 9. There will be technical talks, meetings, flea market, and something for the whole family. Advance tickets are only $1.50 ($2 at the door) from Radio Expo '72, Box WA9ORC, 230 East Ontario St. Chicago IL 60611.

* * *

The Columbus, Ohio Amateur Radio Association has been granted use of the special event call sign WJ4ULY. The club will be broadcasting both phone and CW from Independence KY on July 4. Only US stations will be worked on 40 and 80, DX stations will be worked on 20, 15, and 10. There will be Novice stations active also QSL via W8TO; enclose SASE.

* * *

The Wabash Valley Amateur Radio Association will hold the 26th Annual Hamfest, The VHF Picnic, on Sunday, July 30, 1972, at Turkey Run State Park near Marshall, Indiana. Registration is $1.50 each with no advance registration. There will be prizes, Bingo games for the XYL, big flea market and plenty of good fellowship. Talk in will be on 52.525 and 146.94.

(The following letter, all of it, was written on an airline place mat – Ed.)

I arrived (I'm here in Dr. 9VINR Charan's office, & he keeps bringing in patients, & I just get up & leave when he comes in) here Thursday fr Bangkok, as my time was up that was stamped on my passport. Had been issued the call of HS1AGO while there. Worked many sta with HS call and 9Y4VV Nazir dn in Trinidad, but we never hrd 1 Stateside call. Nazir gave me a 5–9 report. Doc just handed me yr letter of Oct. 71. I'd left the States bk in Nov. Flyin to Lima Peru on my way to visit XS4AA Basil, but stayed in Peru for 3 days visiting hams. Then flu over to Sao Paulo & eyeballed with Brasilian hams, then flu up to Rio where I met & visited many hams in Rio. After 4 days, took off & flu 4280 mi NS to Johannesburg, then drove 130 with Basil to his QTH in Kroonstad. While there for 2 weeks, I wire-brushed & painted his 70' tower.Then contacted K6UJS the night B-4 I left for Cape Town, or ZS1Land, who had my XYL on the LL as a SWL telling him where I was goin. Next day I hitched rides down to C.T. & stayed with many hams in the area ZS1UP was one of them, John, whose son Willie's picture was in the South African paper a week after I was there right on the front page in his plane, upside down flyin over CapeTown.

After meeting many members of my Mormon Church at the services there in CapeTown, I went to the BOAC office & instead of routing me bk to SF via London, she sent me to Nairobi where I met Robby 5Z4ERR & several others & also goin on a small Safari to hunt (but I didn't do any hunting) just went along for the ride in their LandRover & took a few pictures) No room on this paper to elaborate abt my thrilling experiences while there in Kenya. However, after meeting many of the local 5Z4 boys, I caught a plane to Bombay via Uganda & Kuwait. Upon landing at Bombay I had a hotel res at a lovely hotel (paid for by BOAC) because I wanted 24 hrs to contact any VU2 hams, which I managed to do. I met Ali VU2ST & his ham son, who drove me clean across dark Bombay at night (without lights) to his QTH where I met Ali & other both on the air & with the ol eyeball. By this time, it was abt time to catch my flight to Bangkok which was very much appreciated, as we were served a delicious American dinner (after eating stuff I wasn't used to eating) bk there in Bombay.

Well the first thing I noticed after bein in Bangkok a few hrs. was everywhere you looked there, beautiful women . . . all over the place, everywhere.

My visa for my visit to Thailand was up Jan. 28th, we (meaning me) left the 27th (didn't take the XYL B-cause, all she wanted to see was Japan).

Flu into Singapore at 1530, plenty of time to call & make contact with Charan 9VINR, whom I'd QSO'd previously. Said he'd find a place for me. I'd contacted Ruspy DU7ER fr Bangkok on the SEANet with Baddy 4S7PB in Celon as NC & told Ruspy (with my HS1AGO call, that I wd B comin dn to eyeball with Doc Charan in Singapore in a week & if he shud also happen to contact any Victor Sugar stas to B sure & tell them that K6OnlyPrettyGirls (many hams know me by my call) wd B visiting Hong-Kong on his way bk to his QTH there in San Francisco.

So Wayne, I'm sending you this letter to help you better realize just how wonderful a trip I had visiting the many ham friends that we've contacted in past years. I forgot to mention, Thursday evening (when we got in fr Bangkok, we just happened to hit it right because that nite, 9V1NR & I HS1AGO (K60PG) attended the semi-annual meeting of the Singapore Amateur Radio Club, & I got to eyeball many hams I'd QSO'd with, & also I was lucky enough to see the picture I've been trying to see for a long time, bk in the States, Radio Amateurs of the World.

Now, just as soon as the good doctor (who's sitting in his office, filling out dozens of QSL cards, which I think is very commendable) is ready, we're goin dn two a place called Johore Bahru, which is here in Malaysia, to visit some of his friends.

I'm sorry that after QSO'ing Bud 9V1OI many times, he's not here, but up somewhere in Vietnam waters operating MM fr his dredge with the call of W7RMT. Charan & I were drivin to his office, & he said to me, see that nice beam up there on the top of an apt building, well that's Bud's 9V1OI's QTH he left behind.

Many tnx agn Wayne & 73s fr Singapore,

Kenny K6OPG

Following are instructions for obtaining reciprocal operating privileges in Suriname: Because of an agreement between the USA and Suriname, there are no objections against the issuance of licenses to holders of a valid FCC license, during their stay in this country. Applications must be addressed to: The Governor of Suriname, Through. The Minister of Public Works and Traffic, Kleine Waterstraat 8, Paramaribo, Suriname.

With this application an official stamp of Sf 0.30 must be placed and payment of legal charges of Sf 6.00 and an administration fee of Sf 1.00 are due. In order to meet the requirements, send the application and an amount of U.S. $5.00 3 months before the date of arrival to: The Government Telegraph and Telephone Service, Bureel Radio Controle, Keizerstraat, Postbus 1839, Paramaribo, Suriname. The change will be handed to you upon your arrival. Complete and sign the information form that is returned to you and forward it also to The Government Telegraph and Telephone Service.

The license fee per annum is SF 10.00, payable when you are here. Once in Suriname, contact the Government Telegraph and Telephone Service and you will receive further information.

* * *

The *Mobile News* reports that Portugal has signed reciprocal licensing agreements with the following countries: Belgium, Canada, France, Germany, Holland, Morocco, Switzerland, the U.K., and the U.S.

Here is a list of addresses to which to write when requesting licensing information in the Caribbean:

BARBADOS
Ministry of Communications,
Works & Housing,
Government Headquarters,
St. Michael, Barbados

JAMAICA
The Postmaster General
The General Post Office
Kingston, Jamaica

ANTIGUA
The Posmaster
General Post Office
Antigua, Leeward Islands

GRENADA
Ministry of Communications & Works
St. Georges
Grenada, Windward Islands

MONTSERRAT
The Postmaster,
The General Post Office
Montserrat, Leeward Islands

ST. LUCIA
Ministry of Communications & Works
St. Lucia, Windward Islands.

ST. KITTS, NEVIS, ANGUILLA
The Administrator
St. Kitts, Leeward Islands
(Note. There are at present certain administrative difficulties in this

group which may present some problems in obtaining licenses in Anguilla.)

TURKS & CAICOS
The Administrator's Office
Turks & Caicos Islands

BRITISH HONDURAS
The Postmaster General
Belize, British Honduras

DX LETTERS

Amateur operation here in Germany has been a pleasure I never thought it could be back home. Of course, we have our shared bands with commercial services, lots of QRM (some of it intentional) and certain restrictions, but you don't need a KW to work in DXer's Heaven. One thing we do lack is a Third Party Agreement between the U.S. and Germany – no phone patches are allowed.

We would like to hear more Stateside stations calling Europe on 80 meters. Although our band stops at 3800 kHz, the portion traditionally reserved for working DX is 3790–3800, and you don't have to be an Advanced or Extra to work us. If you can work split frequency, you *can* work us. Just give a listen in our DX portion. We usually indicate what frequency we're listening on, but we do listen all over the band, including the General portion.

On 20 meters, we'd work a lot more of you in the Central and Western states if you'd beam the long path over New Zealand. The south polar route works beautifully! Try around 1400 GMT.

Harry K5HML/DL4HW
APO New York 09053

Enclosed are two prints showing the "Ham Quadri" antenna installed on the *Lady Mary*. Mary, WA6VIB, is still located at Manzanillo, Mexico, but is leaving for Acapulco soon.

Bob Wilkinson WA6RFB

THE TRAVELING HAM

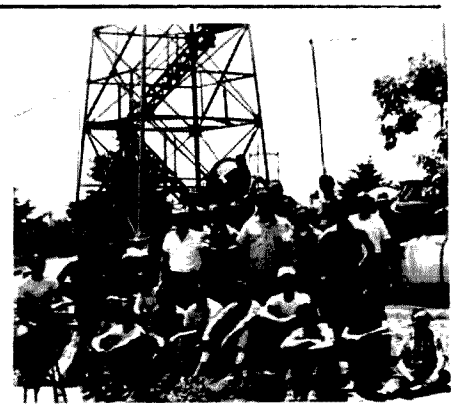
Joe Kasser G3ZCZ/W8

This column is a forum on information and ideas enabling the traveling ham, be he tourist or commercial traveler, to take his ham rig with him and to successfully operate from overseas. The advent of solid state VHF FM and low power subminiature HF equipment has made portable ham stations an everyday occurrence.

The USA now has reciprocal licensing agreements with many countries. Some of these countries, especially in Europe, have a VHF phone (144 MHz and up) class of license that does not require a Morse code test. Thus American Technician class operators should be able to obtain reciprocal permits. These are well worth acquiring because there is a high level of VHF activity in Europe.

Consider the two meter band: in Europe the international two meter (mobile) calling frequency is 145.0 MHz. It is used by both AM and FM stations, but mostly by FM. There is also an international SSB frequency centering on 145.410 MHz. Europe is in Region One of the IARU and as such the two meter band only covers 144–146 MHz. Squeezed into those 2 MHz one finds AM, CW, FM, SSB, repeaters and beacon stations. The band is voluntarily divided: CW operators utilize the bottom 150 kHz, the beacons, although at present all over the band, will soon move up to the top end and occupy the top 50 kHz. The phone operators have the rest using AM, FM and SSB. Many cross mode contacts take place.

There is no six meter band in Europe, but the United Kingdom, Eire, Iceland and Gibraltar have a four meter band at 70 MHz. In the summer, sporadic E skip conditions occur, allowing DX contacts across the continent. This band was a popular mobile band in the UK, until the Class B (VHF Phone Only) license allowed two meter operation without a Morse code test (but with the same technical exam as the Class A (All Band) license. Two meters has become the prime mobile band and has resulted in the establishment of simplex channels for mobile use. For example, 144.48 MHz is a popular channel in London, England.



With the many high-rise hotels, tall buildings and hills dotted all over European cities, the use of a TR-22 or similar hand-held rig results in many contacts. If you think there is no one to talk with, boy are you wrong! The strange accent usually starts a pile-up. Standing near the museums overlooking the base of the Eifel Tower in Paris I had numerous QSO's one winter evening a few months ago both over the air and with curious courting couples at the site. (I would have been up in the Tower except for the fact that it was closed.) Language was no problem, I couldn't even begin to use my French since they all insisted on using English. So with a few words of English, a few words of French and lots of enthusiasm, we managed to communicate.

Next time you go to Europe, take a VHF hand unit with you (get a reciprocal permit first) and have fun. The QSL's are interesting too and make fine souvenirs. How many hams do you know who have QSL cards from G8's, FL's, and DC6's.

Next month I'll write about HF operation, but in the meantime if you have any tips, experiences or ideas to pass along, please do.

Log of W7DXX/1 20 SSB

JX2HK is quite active from Jan Mayen on 14.210. OY9LV is trying split frequency operation. Ole often transmits around 14.220 while listening around 14.300. Thanks to Jim for a very good DXpedition to Market Reef with OJØSUF. QSL via OHØMA . . .EP2TW, ALF via GI3HXV. UH5ØD and UG5ØA are special call signs for Russia, a 50th anniversary celebration. 9N1MM, AF5FX, KS6DY, CN8CJ, OD5BV, MP4BBW SVØWZZ, DL8NU/OHØ, WA2BVU/4X (QSL via W2DYN) are quite active stations and easily worked (they're good operators). Carlton Ross, W9ABA, of Ross and White, operates each Feb. from Grand Cayman Island under the call ZF1BR. QSL via W9ABA. That YI2AZ who appears once in a while on 20 appears to be a pirate.

Here's the whole gang that set up and operated W1DC this last June for the VHF Contest. They operated from Pack Monadnock Mountain in Peterborough, N.H. and put out one whale of a signal on all the VHF and UHF bands.

50 MHz BAND

Bill Turner WAØABI
5 Chestnut Court
St. Peters MO 63376

The skip season is here and if the first two weeks of May are any indication, this should be a dandy year. The band opened nearly every day and in all directions. Reports from various parts of the country confirm local observations that the buildup started in late February. WA5RBI reports Feb. 20th to have been hot from Enid, Oklahoma – the band opened for two hours to Ohio, Pennsylvania, West Virginia and Kentucky. Bob reports another opening March 4th, but with deep QSB, the same general area was involved with the addition of identifiable signals from Georgia, Louisiana, Texas, Illinois and Wisconsin. March 6th brought another opening, this time from the south and southwest. Stations worked included XE1PY, WA7BBM, WA7JEI and multiple 5's. Total elapsed time was an hour and a half starting at 0153Z. On the 8th of March the test pattern and audio of XHY-TV were received on channel 3 and another unidentified Mexican TV station on channel 2 with perfect picture and sound. "Started tuning 6 meters and found the following, 2340Z LU6ACL on AM . . .fair audio, XE3 on CW from Yucatan. At 0012 XE1JP, George, then worked WA5UMP, Jim from Russellville, Ark. on backscatter. On March 9th heard WA1JEX – worked him with the beam South (185°) with 5 x 6 signals both ways. By the way, XE1PY reports 37 straight days of openings there. Also he and Alfredo, LU3EX, have been logging and triangulating a steady carrier on 49.97 MHz. According to their figures . . .from the Northwest of Africa."

Bob, W4GDS, reports having worked XE1PY on backscatter at 2000Z on the 29th of March. Rusty had at the time been working South America for some two hours. Before the band closed at 2127 Bob had worked LU8D1N, LU3EX, LU2DEK, CX1AAX and CE4CP, all with S9 plus signals. I think I'll move South.

Both WB9JFT and WB4VLH report having worked Len, VE4QL. WØGNS noted 'stronger than horseradish" with his groundplane. Better get the beam back up Mac! Others noted as being very active in the past few months include Jack, WA5UUD, New Orleans and Joyce, WB5CUL, working her first skip. I wonder why most 6 meter YL's/XYL's are from the South?

The Itchycoo Park VHF Amateur Radio Society has announced the scores of participants in their 2nd annual "Worldwide VHF Activity." Highest overall score was the 600 points compiled by WA1NNW, who made 60 contacts, all on 6 meters. Other 6 meter leaders were WA3LKO with 250 points and 50 contacts and WA3PNW with 204 points and 51 contacts. Congratulations are due this group not only for sponsoring this "activity" but also for recognizing that a "contest" in which the sole aim is the exchange of callsign, section and signal report is of little value to the participant and a great detriment to normal operation on the band. The 1973 version of this activity is scheduled for 3 PM local time March 10, to 10 PM March 11, 1973. Full details will be published well in advance.

Six meters is looked down upon by many "higher class" licensees as the hangout of incompetents who are unable to pass the General Class exam and it must be admitted that there are those among us who leave something to be desired. But, is this not true of amateurs as a whole rather than Technicians alone? In Websters a technician is defined as "a specialist in the technical details of a subject or occupation" and a little research will disclose that this is exactly the case. Much of the blame for these opinions must rest on the publications which form the communication links between hams. So long as the modulated oscillator/rogen receiver articles are featured and the handbook tells the casual reader that the normal range of a well equipped station is 75 to 100 miles the situation will remain status quo. Anyone who has tried to sell AM equipment long ago discovered that there is no market for it, the average station runs 200 to 1000 watts of SSB and is capable of communication over distances of at least 300 miles. Is it not time too for the only national amateur radio organization to amend its structure to allow the holding of office by the 40% of the total ham population now excluded by the "General Class or above" clause? . . .WAØABI

SSTV SCENE

Dayton was once again a slow scan haven this year and I'm sure if you missed the '72 convention you will want to mark the '73 convention on your calendar. W9NTP and WB8DQT had some interesting gear on display and an "original" copy of the slow scan handbook. WØLMD had his integrated circuit half-cycle smapling monitor on display, and described it in detail during the TV Forum. K4JPE had a storage tube monitor that drew quite a crowd. (The pictures on these tubes get brighter instead of dimmer after being scanned.) There was some very good color fast scan gear and, of course, plenty of W6MXV and Robot units, plus individual booths for each. in what manufacturers designate a P7 Phospur tube. RCA excells in long persistance with in what manufacturers designate a P7 Phospur rube, RCA excells in long persistence with most tubes capable of holding an image 10 to 15 seconds, however, it was noted that some SSTV'ers had bought P7 cathode ray tubes that wouldn't hold an image long enough to view half a picture! Obviously the trend is toward RCA tubes for monitors, and moving the "short persistance P7's" into flying spot scanners.

How about a U.S. sponsored slow scan contest? Wayne and I have discussed the possibilities and we see no reason why this shouldn't be a real blast. This wouldn't be a contest to compete with CQ Electronica of Italy's slow scan contest, but rather in addition to their contest. Certificates to the winners would be no problem, and by the time the contest is on we may be able to come up with a trophy for the overall winner. First thoughts were for a 12 hour period contest late this fall. Since it is already August, we will need to hustle for a contest in, say November or December – what's your thoughts? It would be *your* contest – if you would like to see another slow scan blow-out drop me a card with your suggestion on a date and time. The cards are a must to prove the validity of the contest.

A lot of SSTV'ers have written asking where they might find 931 Photomultiplier tubes. A source may indeed be difficult to locate, for often distributors and surplus houses are rather high ($14.00 each) on them. Have you tried duplicating machine companies? Many stencil cutting machines use one or two 931's and usually these are pulled out when their sensitivity drops slightly (they only apply 650 volts on them, and have no sensitivity adjustment) so they are ideal for flying spot scanners. Another place to try is the local junk yards some autos use these in their automatic head light dimmer, and they can be purchased for 50¢ to $1.00. If you get two that don't match in sensitivity, try separate 3 meg pots in series with the -900 volt supply to them so you can apply a variable voltage to each one – this way you can balance their sensitivity. A "collar" made of heavy paper, sized to fit over the glass of the 931 and a 1/4 x 1" slit for light to reach the 931 grid cut in it can be used to control both sensitivity and picture shading – moving the slotted collar around will shade sides of the pictures. Naturally, moving the slit to the extreme sides will cut out all output. Happy hunting for 931's. . . .K4TWJ

Microwaves

FREQUENCY BAND DESIGNATORS

Paul Schmidt, W9IDP comments on the microwave band designators listed in the May "72 issue of *73* as follows: *"On page 12 Jim Weir has listed. . .the OLD designators. The Department of Defense has. . .issued. . .new designators. (He) should have known that the new designators are official, and are being used in MIL-SPECS and MIL-STD's."*

Paul, I did know that the DOD had issued these new band designators, just as I know that Hewlett Packard had issued their own band designators, and the ITT Handbook had chosen still a third set of letter designators. The question, then, is: what constitutes the "official" nature of a band designation? Taking a rather pragmatic approach to the problem, I say that the *usage* governs the correctness or incorrectness of a symbol. Now, taking any of the wave trade magazines, including the most prestigious of them, you will be hard pressed to find a single reference to the new designators. However, references to "S" band telemetry (2290 MHz) and "X" band waveguide (10 GHz) are quite prevalent.

I do *not* on the other hand, disagree with you. I think the adoption of this system would only be second to the adoption of the metric system in helping the microwaver in his work. It is, in short, the best system of designators ever designed for microwave work. With your kind permission, I will repeat my designators, and alongside them your new system of designation. Perhaps order will come of this chaos yet.

OLD LETTER	FREQUENCY
P	200–400MHz
L	400–1500 MHz
S	1.5–40 GHz
C	4.0–6.0 "
X	6–12 "
K	12–36 "
Q	36–46 "
V	46–56 "
W	56–100 "

NEW DESIGNATOR	FREQUENCY
A	0–250 MHz
B	250–500 "
C	.5–1 GHz
D	1–2 "
E	2–3 "
F	3–4 "
G	4–6 "
H	6–8 "
I	8–10 "
J	10–20 "
K	20–40 "
L	40–60 "

The problem I see arising in the transition period, between the time the old symbols fade away and the new ones replace them, is one of letter confusion. For example, if I told you I had 20 watts at C-band, you wouldn't know whether I had made a breakthrough at 5 GHz, or had something that was fairly common at 500 MHz. Do you see the problem? The same problem arises when speaking of K and L bands. Both systems use K and L so I feel that we must be rather careful in the use of this new system.

Jim Weir WB6BHI

San Diego CA 92123

READER REVIEW

KENWOOD TS-511S TRANSCEIVER

I get equipment "jitters" every couple of years of so and when that time came around recently I was determined to purchase an uncompromising transceiver; usable with good effectiveness on both CW and SSB – *and* be satisfied with it for more than a couple of years. After four months of operation, it appears I made a good choice.

Advertising in 73 affected my decision. I ordered my rig sight unseen, since my dealer in Muskegon did not have a unit on display. I waited four long weeks for delivery due to the West Coast dock strike. I paid the whole wad – full rig price, sales tax, surtax, and shipping. The Kenwood line is fair traded by most of its dealers. While awaiting the arrival of my TS-511S, I became aware that Allied Radio of Chicago had just discontinued marketing a transceiver quite similar in physical appearance, but closer examination showed the Allied unit used more tubes, used 6146 finals (lower PEP) had the CW filter standard, but lacked a noise blanketer. Later, I also noted the Allied units manual was much more complete in circuit and trouble shooting detail than the Kenwood TS-511S. Both units are definiately manufactured by Trio of Japan.

I received the unit two days before New Years – and on New Years Day, it quit; that is, the unit no longer dipped out (resonated). Replacing the finals did not correct the problem. After a few minutes checking, I noticed a loose gear drive on the end of the band change shaft which engaged a gear driven rotary switch in the tank circuit. A dual set screw gear had worked loose, caused by changing bands, and was not changing the rotary tank circuit taps. Since this may happen in other units, I wrote Henry Radio and advised them of the problem. With the unit's cover off, I could readily see the excellent construction techniques used. All circuits are on isolated boards, subdivided by section (i-f, audio, etc.). The TS-511S performs superbly, with only minor quirks. I highly recommend the 500 Hertz CW filter option. This option, with the rig's RIT feature allows an almost separate" transmitter and receiver type quality operation. Even the occasional CW op will want the filter – it is much better than audio restriction type filters. The unit's S meter pins on almost all signals 80–20 meters, when adjusted per instructions. The receiver did not swamp or overload under most signal conditions. The slow/fast agc circuits handled signals properly, and allows operator choice when conditions or modes change. The dial linearity is very good from band edge to edge. Once you get used to 1 kHz readout, you'll never accept less accuracy. The bands are covered in 600 kHz segments and conveniently cover many MARS frequencies without the modifications necessary on other rigs. There *is* a carrier frequency jump from upper to lower SSB, and to CW (with the filter), but in most cases this is no problem. The noise blanketer is effective for impulse type noise such as automobile ignitions, however it is only fairly effective on some car ignitions. Fortunately, I don't live near an expressway.

The transmitter tuneup is typically quick and easy, of the better transceivers available today. One can either tune up by the maximum rf out method or the conventional load and plate tune method. The meter checks the four vital functions on transmit and is an S-meter on receive. 6LQ6's are used as finals. Tune-up key-down is kept to a bare minimum as with all sweep tube rigs. A screen grid on-off switch is provided for improved final neutralizing when necessary. Audio reports are good, and the alc circuitry works well under properly adjusted microphone level conditions. A cooling fan is standard equipment for the finals. Actually, the rig is highly transistorized, and hardly gets warm even over extended periods.

In summary, I'm glad I purchased the Kenwood, and I plan to hang onto it. Parts and service are available from Henry Radio directly, as most of the dealers handling the Kenwood line are qualified to give technical advice and do minor repairs, but do not stock the parts or circuit boards. American manufacturers should wake up to the fact that the Japanese equipment now has a firm foothold in America in terms of price, quality, state-of-the-art designs, and service. My advice – consider the Kenwood. It's a gem.

Your Ham Club - Interesting?

Or Boring!

How are things going at your ham club meetings these days? You say things have been dragging a little? The fellows are tired of having the same old program every week? If this is the situation at your club, now's the time to do something about it while the fellows are still showing up at the meetings.

Let's start by making sure that the club members are reminded to attend the meetings. Your club secretary can send post cards to them, meeting announcements can be sent to the local newspapers and radio stations, and they can also be reminded over your local VHF net, if you have one. If you don't have one, why not start one? Local nets are a big help in holding clubs together. One suggestion made by a club secretary whose club meets bi-monthly, is to mimeograph a sheet of paper with the dates of all the meetings and net nights of the current year, and to distribute it to all the members so they can tack it on the wall of their shacks.

Now that everyone knows on what night your club meets, how do you keep their interest and how do you get them to keep coming to meetings? Perhaps part of the answer lies in a well-organized meeting.

One successful club has their meetings divided into the following three activities.

1. Business meeting – thisportion of the meeting should be long enough to take care of the business and short enough to keep everyone from becoming bored. Your president should have a big gavel and use it. Without at least some semblance of order, nothing will be accomplished. However, don't be too strict. Remember, ham radio is a hobby, and the fellows do come to the meetings to enjoy themselves.

2. Coffee and doughnut break – this isn't absolutely necessary but it is always welcome. You know how everyone likes to raid the refrigerator during the commercial. Try to buy your own coffee maker. It will come in handy for other activities such as a field day, mobile outings and picnics. Also, to keep from drawing upon the club dues for refreshments, keep a "kitty" next to the coffee maker and let the fellows "feed her" according to the dictates of their consciences.
3. The planning activity – this is by far the

most important part of the meeting. Let's start at the beginning: First, an activities committee and chairman should be selected and be responsible for all meeting programs. The chairman should be a dynamic, vigorous person with a forceful, but pleasing, personality. Choose him carefully, for he might well be the most important member of your club!

Below is a list of some suggested club activities. Once you get to thinking about it, you'll be able to add several more to the list.

1. Try a field trip to the electronics department of one of your local industries.

2. Movies are always welcome. Get a list of movies and film strips from QST, your local library, and your local phone company.

3. Have a demonstration. This could be an artificial respiration demonstration by a member of your fire department or Red Cross chapter, or the display of a piece of gear constructed by a member of the club.

4. Construction projects. This can be anything on which the club decides, from UHF gear to a coil loaded bobby-pin vertical for 80 meters.

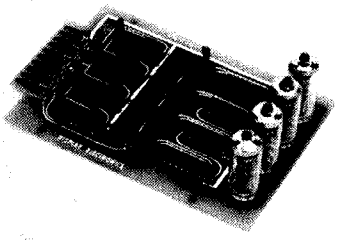
5. A question-and-answer forum. Get three or four of your "brains" to sit on a panel and let them solve problems tossed at them by club members. It will be a lively evening!

6. Speakers from business and industry. Another idea is to have the members talk about their pet interests, such as DX, traffic handling, etc.

7. Have a joint meeting, picnic, or dinner with another club. If you are really objective in your thinking, you might even do this with a CB club!

8. Mobile hunts. About February, a committee should be appointed to decide the ground rules for your summer mobile hunts. This should include bands operated, area covered, gear used, and prizes. Mimeographed maps of the area to be covered during the hunt are nice to have, as well as picnics after the hunt.

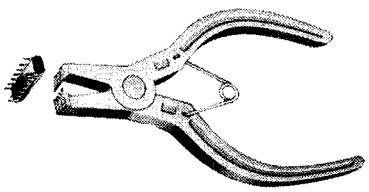
9. Contests. Who can work the most countries from one meeting to the next? How many stations can a club member work in an hour? Who can work the greatest distance with the least amount of power? Keep thinking – you'll come up with many more ideas.



10. Have an auction. It is plenty of work but it can be lots of fun as well as a profitable venture for the club. Careful planning and lots of publicity is the secret of success here. Try to get a good auctioneer. He should be witty, comical, bubbling over with personality, and have plenty of gab.

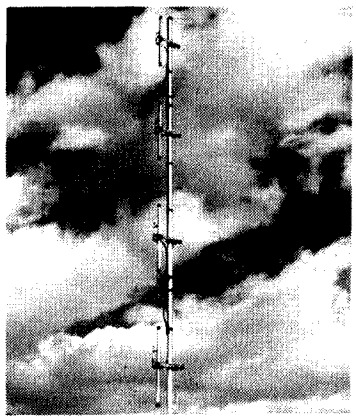
One way to cut the club in on the profits is for the club to take 5–10% of the price of the piece of gear that is being auctioned. It is a dandy way to add to the club treasury once or twice a year.

Well, that's about it, fellows. Try to put a little life into your club and you'll watch it grow and prosper. Also, you'll have lots of fun doing it.



...W8DYF

NEW PRODUCTS

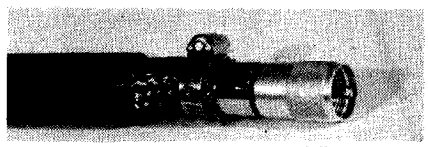


CM COUNTER AND DISPLAY MODULE

The new Series CM Counter and Display Modules, provides a convenient reasonably priced solution to a variety of counting and display requirements. Modules in the series are available in several different numbers of digits with each digit including a decade upcounter, memory latch, decoder-driver and readout tube. Since the incandescent readout tube operates from 5V dc it eliminates the need for an additional power supply. Each character is nearly 1/2 inch high and will provide an attractive, high contrast display when viewed through the polarizing filter accompanying the module. The 7400 series TTL integrated circuits and readout are assembled on a G-10 fiberglass printed circuit board. Connections to the module may be made through the rodium plated edge connector or directly to terminals. The module features zero blanking and a lamp test control. Each module is thoroughly inspected and tested before shipment. A complete schematic and instruction sheet is included with each unit. Write to *Display Electronics, P.O. Box 1044, Littleton, Colorado 80120.*

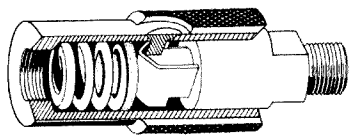
NEW TOOL

Experimenters will delight at this new integrated circuit inserter/extractor. No more will you need to keep a bottle of iodine on the bench. The Starnetics unit operates like a pair of pliers with a spring loaded handle so that you do not squeeze the DIP into a squashed spider. Metal teeth also act as a heat sink while soldering. And to prevent waste, leads on old ICs can be straightened. This is certainly a universal device for the home builder. It costs less than twenty dollars from *Starnetics, 10039 Riverside Dr., No. Hollywood CA 91602*



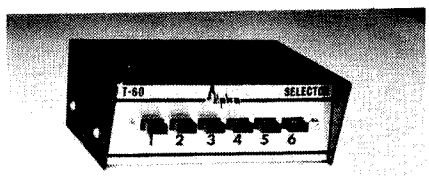
REPEATER BUILDERS NOTE

Cush Craft announces the addition of two new models to their Four Pole antenna design. The Four Pole is a series of four stacked dipoles for amateur FM applications. Four Poles are supplied with the dipoles mounting booms harness and all hardware. Center support mast is not supplied which allows the user to custom select a mast for his installation or to tower mount the antenna. Gain figures for the antennas show 6 dB omnidirectional and 9 dB semidirectional pattern. Available for the 144, 220 and 435 MHz amateur bands. For more information, write to *Cush Craft, 621 Hayward St., Manchester NH 03103.*



PORTABLE MONITOR RECEIVERS

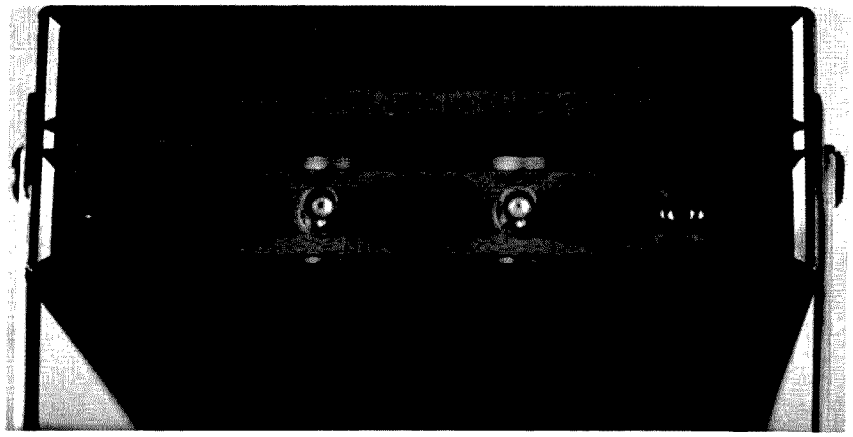
Now you can listen to the repeaters wherever you go. Tune them in with the Hallicrafters portable monitor receivers. These radios feature continuous tuning over the 27–49 MHz or 144–175 MHz ranges. They have adjustable squelch controls that eliminate background hiss. The rf stage lets you hear the weaker signals and the tuned i-f stages let you separate stations on nearby frequencies. Each of these radios has a nine transistor complement and provides all the sensitivity and audio that the average repeater monitorer wants. Price of these units is under forty dollars. For more information, write to the *Hallicrafters Company, 600 Hicks Rd., Rolling Meadows IL 60008.*



COAX CONNECTOR

At last! A low priced connector for RG-17/U coaxial cable. RG-17/U coax is a low loss and flexible cable suitable for amateur use. It is also inexpensive when compared with alumium hard line and other low loss transmission lines. This connector enables the RG-17/U to be connected directly to an SO-239 receptacle without an adapter. The connector may be used at frequencies up to 550 MHz with negligible insertion loss. In addition, no special tools are required for a solderless installation that is completed in minutes. For more information write *Wayne Smith Products, P.O. Box 46521, Bedford, Ohio 44146.*

QUICK ANTENNA DISCONNECT



NEW-TRONICS CORPORATION announces the first available 100% stainless steel Quick Disconnect for instant press and twist removal of a mobile antenna from its mount. Lifetime performance is assured in this heavy duty assembly with special encapsulated design and stainless steel spring for freedom from sand, dirt or ice jam-ups. The Model QD-1 will accommodate small, medium or large antennas with 3/8"-24 base. For additional details write: *NEW-TRONICS CORPORATION, Sales Department, 15800 Commerce Park Drive, Brookpark OH 44142.*

NEW TONE ENCODER

Repeater users who frequent tone-entry repeaters should consider the new Alpha Electronics MT-60 tone encoder with six selectable tone frequencies. Each tone is completely adjustable from 20 Hz to 300 Hz, and the tones can be continuous or pulsed. The beauty of this unit is that it also is a tone decoder. Several hams can have a selective calling system so that only the desired station can break the squelch. Different combinations of encode and decode functions can be made. The tones are determined by plug-in modules. Write to *Alpha Electronic Services, 8431 Monroe Ave., Stanton CA 90680.*

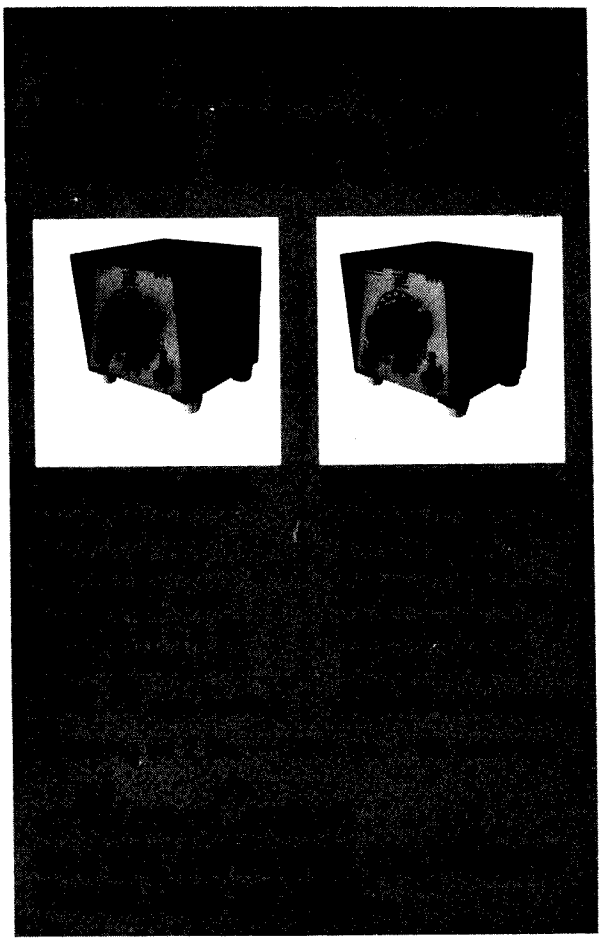
The HEATH IB-102 PRESCALER

With the greatly increased activity on 6 and 2m FM the average ham is in dire need of a means for frequency measurement above 30 MHz. The Heath Company had a nice 15 MHz counter (the IB-101) well within the normal ham's equipment budget. But a method or device was needed to allow their 15 MHz counter to measure to better than 150 MHz. To fill this need Heath introduced the IB-102 prescaler. This unit will take a 150 MHz signal and divide it by 10 and thus allow the counter to read it as a 15 MHz signal.

The Heath IB-102 prescaler is enclosed in the same attractive case as their counter. The unit is all solid state of course, using both FET and bipolar transistors plus TTL integrated circuits. With Heath's excellent instructions and assembly manual the kit goes together in four or five evenings of work.



The 50Ω input to the IB-102 is fed to a broad band amplifier. This amplifier in turn feeds an IC that functions both as a trigger circuit and as a level translator to get the input signal to the proper TTL switching levels. The output of the trigger circuit is fed to a second IC that provides a divide by 2 function. The divide by 2 stage is followed by an IC divide by 5 stage for a total division of 10. An additional IC decode (divide by 10) stage can be switched in to give a divide by 100 as well as a divide by 10 function. The output from the various divide stages is fed to an output buffer amplifier This gives the proper impedance transformation from the relatively low impedance used in the ICs to a high impedance output that will match the high impedance input of a frequency counter. Provisions are also made to operate the scaler "straight-through" when the divide by 1 function is selected.

The Heath IB-102 offers several important features not found on any of the other prescalers offered on the ham market.

First: It has an imput level meter so that you know that the prescaler has an adequate input signal level for proper operation. No more do you have to adjust the input coupling to the prescaler and see if your counter reading changes. The meter tells you the whole story.

Second: The IB-102 has an input sensitivity control on the front panel so you can adjust the input broadband amplifier gain to keep the input level meter in the green area. There is even an input test button on the front panel. If you push it (with a signal applied to the prescaler) and the input meter stays the same, you have enough input gain. If the meter level changes you need to adjust the input gain control or provide more input to the prescaler.

Third: The IB-102 is the only prescaler to have a divide by 100 function. This doesn't mean much to you if you have a 15MHz counter and thus can use the divide by 10 function to read 2 meter signals. BUT if you are one of those who has one of those surplus 2 MHz or 10 MHz counters from MARS, the divide by 100 function saves the day – you too can read 2 meter signals. True, you lose a significant figure on the right and thus only read to the nearest 100 Hz with a 1 second gate time. But on most of those counters you also have a 10 second gate time. By using 10 second, you regain your lost digit and read to the nearest 10 Hz!

The input sensitivity for 2 meter work is excellent. A 90° right angle BNC connector was put on the input jack. A little 19 inch whip antenna was fitted to a male BNC connector and that in turn was plugged in the right angle connector. Now the prescaler was all set with a 1/4 wave 2 meter vertical antenna. No trouble was encountered in getting the input meter "in the green" and good counter readings from a 2W hand-held 2 meter transceiver across the room. Even mobiles pulling up in the driveway 15 feet away could be read.

Once again the Heath Company has seen the ham's need and has zeroed in on the problem. Result: a new product that exactly fills the need and is less than $100. That's a hard act to follow. The IB-102 is a most satisfactory piece of test gear and should be a companion to the counter in your lab. It lets you accurately measure frequencies that you could only guess about before. With the IB-102 available, there's no excuse for being off frequency whether it be on FM or moonbounce or one of the MARS VHF channels.

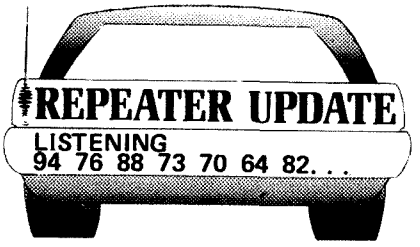
5. Additional components (purchased from others). 40.00

MARS



From your response to earlier MARS articles, two things are obvious: If you are already a MARS member, this column is old-hat—you are familiar with the operation, the meetings, the awards, etc. If you are a non-member, such news items are of no great interest—more importantly, you want to know what MARS membership could mean to you. Therefore, in the future, I will concentrate on the MARS story, its purposes, plans and aims, and how you can broaden your horizons and profit greatly as a result of your membership.

Consider, if you will, an organization of thousands of dedicated hams, all using the same procedure, the same format, the same phonetics for a given letter of the alphabet—and all bound together by a common interest, military communications. Generally, hams are a friendly lot, by nature of their hobby. MARS membership embellishes this friendship—members become close friends through their association day after day on MARS frequencies, constantly adding the newer members to their own individual circle of friends and acquaintances. Example: Third US Army MARS instituted the "buddy" system several years ago. A new member is assigned a "buddy"—an older member who lives nearby—to help the neophyte get on the air, or to answer any questions concerning the MARS operation.

To reiterate, you don't become a MARS member *instead* of becoming a ham—you become a MARS member *because* you are a ham! The basic requirements are: a valid amateur radio license (yes, you can join as a Novice or Technician); at least sixteen years of age; an interest in military radio communications; equipment capable of operation on the frequencies to which you will be assigned—in most cases just outside the eighty or forty meter bands. To become more familiar with the MARS operation, you might like to listen to some of the Nets. Try 6997.5 kHz, 7305 kHz, 7358 kHz, 7360 kHz and 14,405 kHz in the daytime. During the early evening hours listen on 4001.5 kHz, 4010 kHz, 4015 kHz, 4020 kHz, 4025 kHz and 4030 kHz. WAR Broadcasts, consisting of approximately 200 words, are transmitted Mondays at 8 PM Eastern Time on 3347 kHz, 6997.5 kHz and 14,405 kHz at 15, 20 and 25 words per minute. Such transmissions are good code practice opportunities.

If you are equipped to copy Teletype, the same message is transmitted on the same frequencies on Tuesday evenings at 8 PM Eastern. Army MARS stations use the prefixes A, AA, AD or AL before their usual district number and final letters, i.e.: W4SCF is A4SCF in Army MARS. Air Force MARS stations are identified by AF prefixes, while the Navy MARS program utilizes N prefixes. A brochure outlining the MARS operation will be sent to those who are interested. For the brochure, for MARS applications for any branch, or for any information concerning MARS, simply address:

FM REPEATERS IN ENGLAND

A "UK FM Group" has been formed to press for permission to establish FM repeaters in the UK. So far, such repeaters are not allowed by the authorities. The following are some FM channels (simplex) in common use in the UK:

144.350 Calling channel, Southwest and South Wales area
144.400 Working channel for above area
144.480 Calling channel, London area
144.600 RTTY and FM working channel but RTTY priority
144.800 Working channel matching above calling channel
145.000 Mobile calling channel
145.150 Calling channel (little used at present)
145.200 Working channel matching above calling channel

W2EEY

ARE YOU TAKING 2 METERS TO HAWAII?

Hawaii repeaters have been expanded with a view towards better coverage of the islands and better service for the visitor.

146.28/146.88 is now on Diamond Head, giving full coverage of your stay in Waikiki. This repeater, KH6EQF, is linked on 450 to KH6EQK on Mount Haleakala. With its 10,000 foot elevation, KH6EQK gives good coverage on 146.34/146.94 throughout the islands of Maui and Molokai, and coverage on parts of northern Oahu and western Hawaii (The Big Island). Plan on .34/.94 for your island hopping, but you may want .28/.88 in Waikiki unless your hotel room is high and easterly facing Haleakala, 100 miles away.

146.20/146.80 is primary Honolulu frequency, thru a new repeater at Tripler Army Hospital. There are over a hundred users on this repeater. Consider this pair if you plan an extended stay.

146.16/146.76 is a local-area frequency. One repeater, KH6FOX, is located at the University of Hawaii, with coverage into Waikiki. Another, KH6EQL, is located in north-central Oahu at Waialua. A third, KH6EQN, is under construction at 8,000 feet in the Hilo area on the Big Island, with plans for a link to reach the Haleakala -Diamond Head complex. These three local repeaters, all on 146.16/146.76, are lightly loaded and serve as escape routes when the big ones are busy.

There are no tone-access requirements on Hawaii repeaters.

Hawaii amateurs welcome ham visitors, and hope that this explanation, more extensive than is possible in the various charts, will help you to turn up in Hawaii with the right fistfull of crystals.

New Product

100 MHz COUNTER KIT

Heath Company has introduced the IB-1101 Frequency Counter with a 1 Hz to over 100 MHz range and a list of features before now unheard of in low-cost counters. The Heathkit IB-1101 has an input circuit that will accept input levels from less than 50 mV to more than 200V, depending on frequency. The full five-digit readout can be expanded to eight-digit capability by simply using the overrange circuitry. And to make accurate readout even easier, the decimal point is automatically placed with range selection, while MHz, kHz, overrange and gating are indicated by front-panel lights. A one megohm input impedance and low input capacitance reduce the chance of circuit loading.

Priced at just $269.95, the IB-1101 can be assembled in 10 hours. The 26 digital ICs and five cold-cathode readout tubes plug into individual sockets. All other components mount neatly on one double-sided circuit board. For further information write *Heath Company, Benton Harbor MI 49022.*

INFRARED INTRUSION Detector kits. Transmitter: $24.00, Receiver: $22.00. Kits include board, board-mounted components, emitter/detector. See March Popular Electronics. H. Olson, PO Box 339, Menlo Park, CA 94025.

FOR SALE Heath SB-610 Scope. 3 months old $85. Johnson 6 N2 VFO $35. Jim Gysan 53 Lothrop St. Beverly MA 01915 (617) 922-3850.

FOR SALE: HEATHKIT compact kilowatt HA-14 linear, good condition, and homebrew power supply. $110. W2KPE 147-11 76th Ave., Flushing NY 11367.

THREE CHANNEL HANDIE-TALKIE complete with crystals for 04-64, 16-76, and 94-94. Also includes desk stand charger and nicad battery. $315 value. Brand new. First check for $250 gets the whole package. Under manufacturer's warrantee. Radio Bookshop, Peterborough, NH 03458.

CLEANING OUT SHACK garage and attic. Six new surplus 6C21 Triodes, misc. XMfr's, chokes, caps & xtals. List available. WA7OTN, 185 E. 550 N., Bountiful UT 84010.

FM IC-20 & REGENCY – 2A OWNERS Now available, 4 frequency tone burst oscillator, internally mounted. $29.50. Bob Brunkow 15112 S.E. 44th Bellevue, WA 98006. Phone: 206-747-8421.

COMPUTER SHACKSIGNS printed on computer paper, block letters by IBM-1130. Beautiful! Frame it! Call alone, or anything. 13½" x 11", 2 for $1.00. WA2BCY, Lambert, 240 Garth Road, Scarsdale NY 10583.

SALE – LIKE NEW with original instruction book (3) art 13 autotune aircraft transmitters with all tubes, $50.00 each. Also: (3) new panadapters, BC 1031 with spare tubes and power cord and original tech. manual. $70.00 each. Shipping costs collect. W3RYJ, RD 4, Box 368, Reading, PA 19606.

FIGHT TVI with the R.S.O. Low Pass Filter. See p115, March 1972, *73*. Write for brochure. Taylor Communications Manufacturing Company, Box 126, Agincourt, Ontario, Canada.

WARREN, OHIO ARA's Family Hamfest, August 20. Giant fleamart, swimming, picnicking, all free. Displays, mobile checkin. Camping available. Yankeee Lake, Rt. 7 near I-80. Details: QSL W8VTD.

IRCC PICNIC/HAMFEST Try it! You'll like it! July 9, Fairgrounds, Lafayette, Advance $1.50, Gate $2.00. Order: SASE to W9YIP, 477 Robinson, West Lafayette, IN 47906.

EARLY VACATION Then tear up that ticket to Tahiti. There'll be more fun at the ARRL Hudson Division Convention, October 21-22, Hilton Motor Inn, Tarrytown, NY. Exhibits, lectures, 2 meter FM, RTTY, contests, gabfests, New York sightseeing. Fun! No charge for a suntan. For information write Dave Popkin, WA2CCF, 303 Tenafly Road, Englewood NJ 07631.

WANTED 10 meter FM base station. Contact Keith W7DXX/1 at *73* Magazine.

FLASH
EUROPE ORGANIZES FM WITH 600 kHz SPLIT

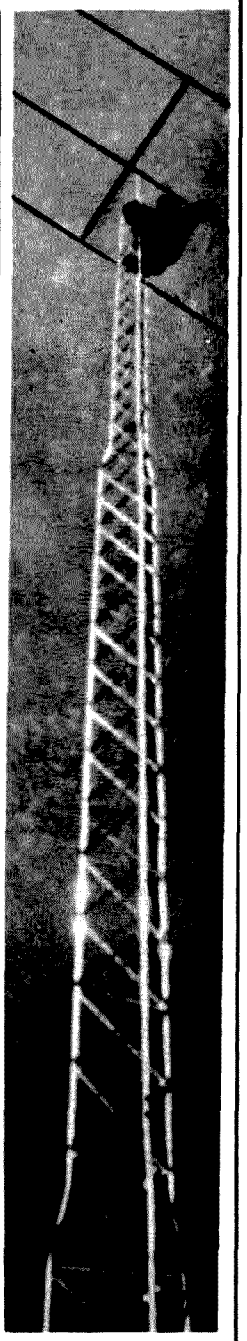
Just got a telephone call from Kris Partridge, G8AUU in London. He says Region 1 had a meeting in The Hague May 15-19 and they made the big decisions for FM. As to how the decisions will affect FM in England, they have set up 33 repeater channels. There are 1 through 33 covering 145 to 146 MHz. Starting at 145.025 each channel is in 25 kHz steps to 145.825. Channels 1 through 9 are repeater inputs, channels 10 through 19 have not been allocated, and channels 20 through 33 are repeater outputs. Power is limited to 15 watts erp and the deviation in narrow band. (In England wideband is 5 kHz and narrow band is 3 kHz.) Also, tone burst of 1750 Hz is required. The first repeater on the air will be GB3PI in London with the input on channel 6 and the output on 145.750. 145.000 is the national simplex frequency. We will have full details next month.

. . .W7DXX/1

Center Tap a Pot With Silver Paint

After several hours of a Saturday morning were spent trying in vain to locate a 100K center tapped linear pot in local stores, it was decided to try another tack. A regular 100K linear pot and a bottle of silver conductive paint were bought. The paint is the type sold for the purpose of repairing damaged circuit boards and while not cheap, it does have a myriad of uses and will last a long time.

The rear cover of the pot was removed and a careful calculation made as to the exact center of the resistance element. (Translation: I eyeballed it and dobbed the paint in what looked like the center) The stripe of silver was continued across the phenolic to the nearest point of the brass shaft bushing which served to attach the pot to the panel. Success! It worked exactly as planned. Please note that in the example cited the center tap was to be grounded. In circuits in which the tap is above ground other arrangements would need to be made. Perhaps a notch cut in the back cover to clear a wire which could be glued to the phenolic and the conductive paint connected to the bare end.



The left over paint will be useful to put in connections on PC boards which were forgotten before etching or required by later redesign in addition to its intended purpose.

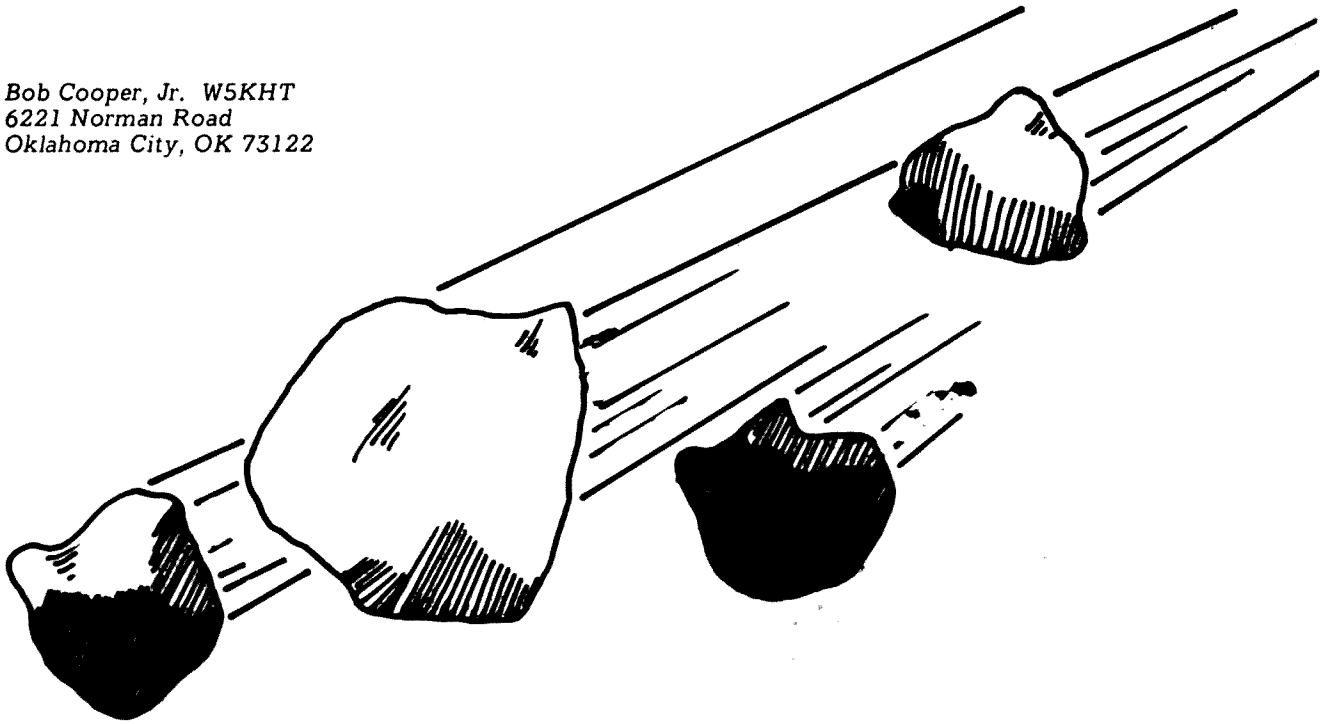
Eric Falkof K1NUN
Assistant Editor

VHF SPECIALISTS FM-10-50 amplfier

VHF Specialists of Vienna, Virginia, a relative newcomer to the amateur market, has introduced the new 2 meter class C amplifier for FM work. The new unit has been designated Model FM-10-50. The amplifier is somewhat unusual as it utilizes modular type of construction. This technique allows the manufacturer a large degree of flexibility in that different modules may be used to form many different amplifiers with various input and output power levels. The FM-10-50 is a two stage type of class C amplifier using Balanced Emitter Transistor in both stages. The BET type of device can withstand almost infinite VSWR and yet remain undamaged. This is an important factor should you have a broken antenna or shorted feedline. Each amplifier stage is mounted on its own small glass epoxy (G-10) printed circuit board. The two p.c. boards are then mounted side by side in the cabinet and electrically coupled together. The input amplifier or driver stage p.c. board also contains an rf sensing circuit and dc amplifier that functions as a relay drive. The relay being driven is a double type of TR relay on a DPDT form. In the receive mode the relay contacts are connected to allow the signal coming from the antenna to bypass the amplifier on their way to the transceiver. In the transmit mode when the transceiver is keyed the rf sensing circuit pulls in the TR relay thus switching the amplifier in between the transceiver and the antenna. When the transceiver mike button is released the amplifier is once again automatically bypassed for receiving.

In actual testing the FM-10-50 would respond to input power levels as low as 1W while producing 22W output at 13.6V dc. 10W in yielded 42W out and 15W input produced 54W output.

While quadrupling your transmitter power doesn't actually double your range (except in theory) it does do a lot to fill in those "not so hot spots" that you are noisy into the repeater each time you go there. It extends your "outer limits" to usable coverage area where you can put a decent signal into the repeater for as far as you can hear it pretty well full quieting.



It is an interesting point to note that the VHF Specialists FM-10-50 also uses 100% all-American parts throughout. America is the unquestioned leader in rf power transistors as evidenced by the fact that all four manufacturers of 2 meter class C power amplifiers have stuck to all-American parts and active devices.

The FM-10-50 is mounted in an aluminum case with a top mounted heat sink that is common to both stages. Installation is simple: connect to 12V dc and connect to your 2 meter rig and antenna. No tune-up is required.

Meteor Showers:
NEW ROLE IN VHF DXING?

More frequent than you might guess, meteor showers can provide some interesting DX possibilities — but the key is in taking the proper advantage. Here are some hints and a lot of new data. . .

Nearly twenty years have passed since the first amateur use of meteors on 144 MHz, but strangely enough our apparent understanding of the mechanism is still quite cloudy, and our techniques for use of this propagation mode haven't changed much.

Basically, communication via ionized meteor columns is closely akin to sporadic E skip; only the duration is so short as to force users of this medium into a set of rigidly timed transmitting and receiving sequences if a contact is to result.

Unfortunately, the E layer of the ionosphere (extending from an average minimum height of 45 miles to an average maximum height of 85 miles above the surface of the earth) is still very much a mystery to us, in spite of various scientific studies.

Techniques Utilized

Nearly all amateur radio work with meteors above 50 MHz occurs on 144 MHz, and during periods of the year when *meteor showers* are forecast. Even within the shower periods, schedules are maintained (as a rule) only during those time slots when peak meteor activity is forecast Effectively, this precludes amateur (radio) observations during the other 99 percent of the year – periods during which we know only that meteor activity is not *forecast* to be exceptional. In effect, our cur-

rent use of meteors on 2 meters skims only the top from the year's meteor crop, leaving the rest unobserved and unmeasured.

Additionally, the amateur's use of meteors has been for the sole purpose of gathering new states for 144 MHz DX chasers, and once a contact has been made, seldom is repeat work attempted.

Thus we have a built-in situation where we annually return at the same time, over the same or similar paths and reverify what we have known for as far back as 15 years, seldom attempting to seek out new information.

In the spring of 1969 I made a crude study of meteor column reflection. I chose to monitor for meteor skip on three separated frequencies, essentially over a two-octave range, utilizing commercial signal sources. Channel 7 video (175.25 MHz), FM broadcast band (93.7 MHz), and channel 2 video (55.25 MHz) were simultaneously monitored and, where practical, recorded. The monitoring system in use during the one-year period was basically as shown in Fig. 1.

The main areas of interest during this study were as follows:

(1) Determine the relative frequency of bursts encountered at each of these three (low, mid, upper) VHF regions.

(2) Determine the correlation, if any, between bursts in one frequency region and either or both of the other two regions.

(3) Measure the hourly, daily, and monthly burst *counts* (where possible) *within* each frequency region (and overall for all three regions).

Note: "Bursts" as used herein, refer to receptions of 1–2 sec. "Pings" are shorter, "superbursts" longer in duration.

Amateur experience at 50, 144, and 220 MHz indicated that the *random* meteors produce sufficent ionization for CW (or SSB) communication on 50 MHz virtually any morning of the year in the 0500–0800 period over paths of 400 to 1200 miles. At 144 MHz, CW exchanges can be demonstrated by well equipped, properly manned stations equally as often, although most of the exchanges would not qualify as a contact. Limited work at 220 MHz indicates that random morning exchanges are unlikely, but not completely ruled out. WØDRL, incidentally, has demonstrated that exchanges on 432 MHz are possible during dense shower periods, with contacts

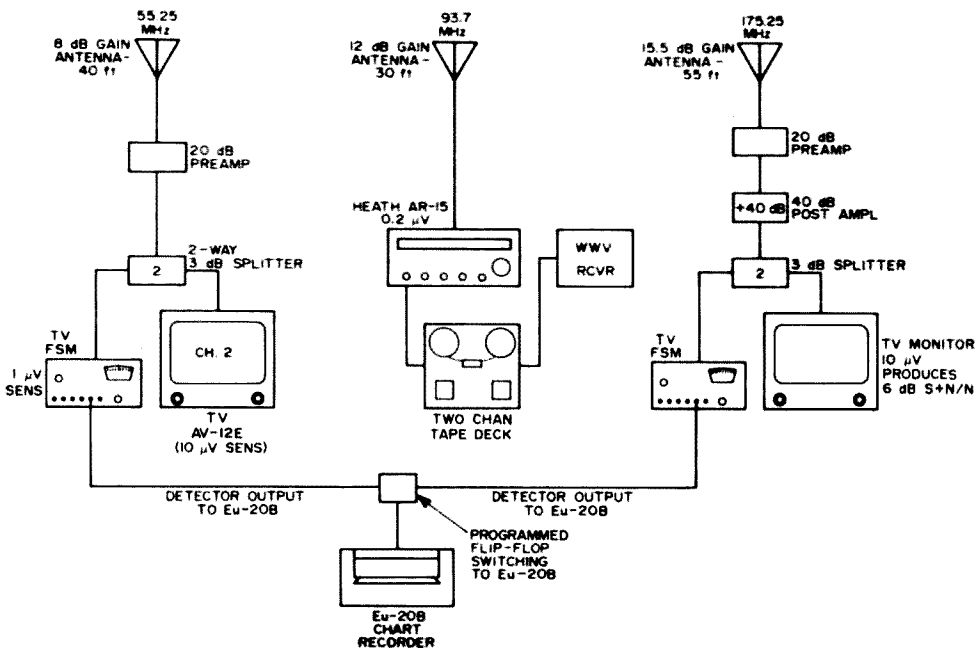

Fig. 1. Equipment set up for year-long, three-frequency monitor experiment.

sure to follow as techniques are improved.

Basic Mechanism

Space debris, consisting mostly of fine particles of dust and small rock, is scattered throughout the solar system (and probably the galaxy) in a semirandom state. If the entire solar system is measured for space debris concentration, over the billions of cubic miles contained therein, the debris would appear to be quite evenly distributed. However, if a relatively small area (such as a million square miles) is studied, a less even distribution of the debris becomes evident. And as we confine our study area to even smaller regions, *substantial* variances in the seemingly even distribution of the debris become apparent.

This bunching of debris is quite well known, manifesting itself (from our earth-bound vantage point) as *regularly scheduled* meteor showers.

Not so well known is the fact that during nonshower periods the number of meteor particles swept up by the earth is also subject to considerable variation. From tables of visual observations during the 3–4 a.m. (local standard time) period, radio meteor activity in the 5–7 a.m. period can be quite accurately predicted. This has been verified by a number of observers.

This space debris which travels throughout our solar system may travel in our own *plane*, in an adjacent plane, or in a plane that is *tilted* (with respect to the earth revolving around the sun). We may encounter the same debris region each year, in our revolving about the sun, or less often than annually.

All studies of meteor debris made from the earth began as visual studies, and were therefore limited to those periods of the day when there was local darkness and clear skies. Radar returns from ionized meteor columns have evolved as a minor research program by a number of university programs, and this has helped to fill in the important time gap when the sky is not dark or clear enough for observation. (This is especially important in the summer period when daylight is longer, the peak period of the year for meteor activity.)

As the earth revolves about the sun, it is also rotating on its own axis. As Fig. 2 shows, the leading side of the earth (the side facing into the direction of the earth's travel through space and around the sun) is

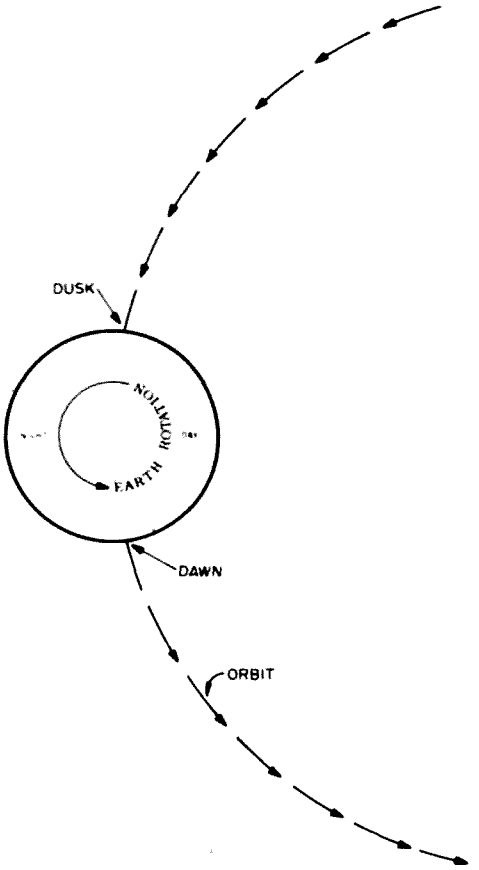

Fig. 2. Sketch shows direction of earth travel and rotation with respect to sun.

at the 6 a.m. (earth time) point. And the 6 p.m. point (the opposite side) is directly behind the earth's leading edge. As the earth travels through space, it overtakes slower-moving space debris caught ahead of it. Captured by the earth's gravitational field, the debris is pulled toward earth. At the same time, space debris moving in essentially opposite directions to the earth's movement is met head-on. The earth literally runs down much of the debris caught in its path, and unless deflected away from a true course, this debris is drawn directly into the E layer.

The density of gaseous particles in the upper layers of our ionosphere is quite well known. The density of the F layer, for example, is considerably lower than the density of the E layer.

The speed of the debris particle (which is dependent upon its original trajectory before it was caught by earth gravity) determines to a large measure the friction between the particle and the gaseous contents of the E layer. As the particle is drawn closer to the earth's surface (lower and lower in the E layer), it encounters denser gaseous materials, increasing the friction on the surface of the particle and eventually heating the particle to a temperature sufficent to cause it to ionize a trail of gaseous materials in its wake as it trajects towards the lower reaches of the ionosphere. Eventually the friction heat of the particle is sufficent to cause it to ignite or burn, which produces the familiar shooting star. Visual ignition of the particle is not required for an ionized meteor column to form in the E layer, however.

The ionized column is in actuality a *cone*, and the electron density within this conal region is sufficent to cause refraction of VHF radio signals, much in the same way the regular E and F layers refract lower-frequency signals on a regular and daily basis.

As we can see in Fig. 2, the daybreak period has a natural advantage over other periods of the day because of the relatively greater number of particles which the earth sweeps up during this period.

By the same token, the twilight period is traditionally the slowest period of the day – principally because for any debris to be caught up by the E layer in that period of the day, the debris must either be traveling in the same plane and direction, but at a *greater* speed than the earth, or be

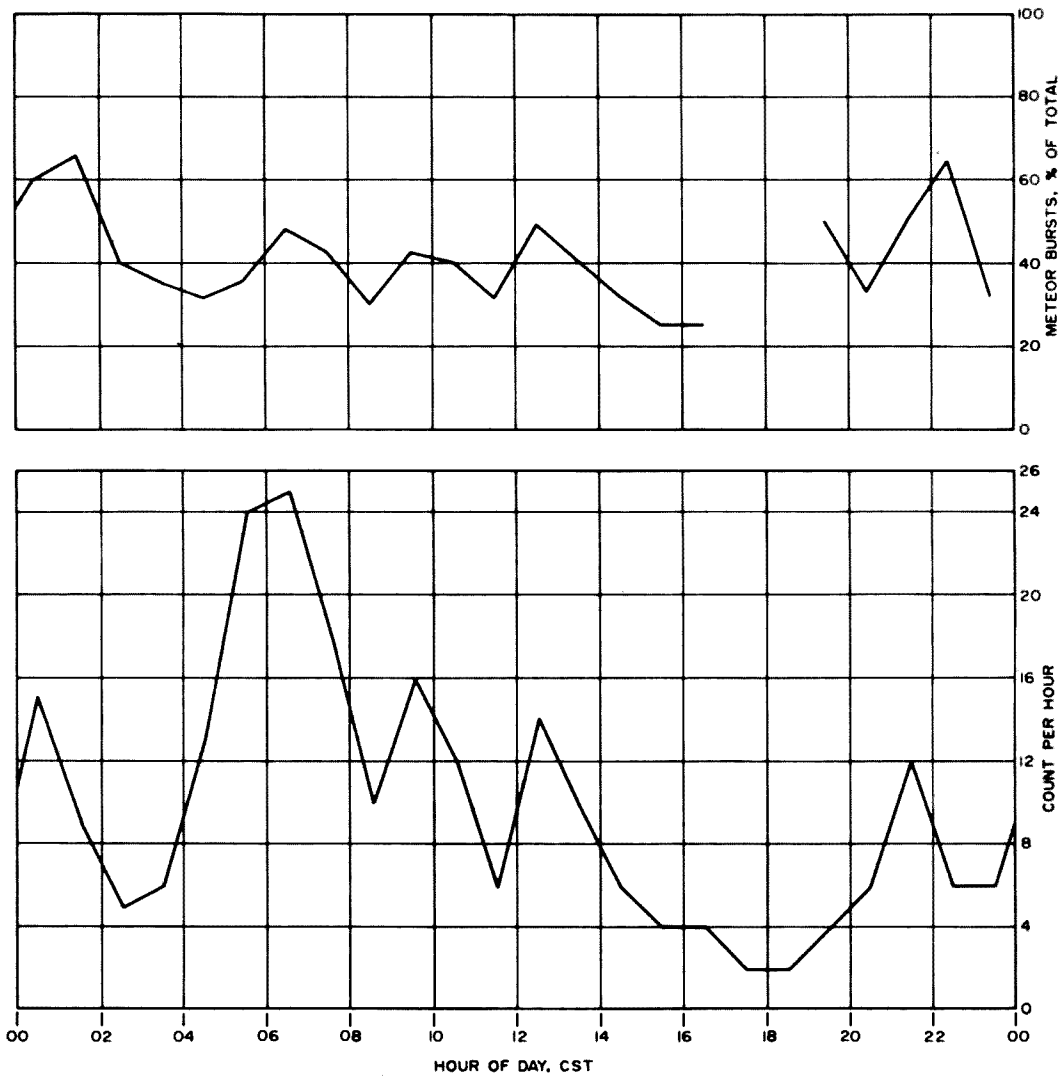

Fig. 3. Average activity, based on 41 day monitoring period (93.7 MHz). The lower portion shows average count of bursts on an hour-by-hour basis; the upper chart lists the percentage of bursts that were greater than 1 second in duration.

traveling in a plane tangent to the earth and at right angles to the earth's plane of movement, passing into the E layer from the side. This happens not very often.

In a scholarly study entitled *Meteors, Meteorites and Comets*, Smith pointed out that radar studies of VHF meteor reflections substantiate the 5–7 a.m. period, *but* noted there were unexplained increases in meteor reflection counts also around 10 a.m. and again around 10 p.m. To this I must also add that based upon my own observations and chart recordings, there are also decided subpeaks in the noon and midnight periods.

My own method of observation is simple to duplicate: The FM receiving system of 93.7 MHz is recorded on a Heath model EU-20B servo chart recorder. The presence of rf carriers (down to 0.1 μV) and their relative strength over a 20 dB range (limit of EU-20B dispersion without a dc log amp), are recorded at a standard speed of 4 in per minute. Simultaneously, a two-track audio recorder preserves the audio information (from the transmitting station) on one channel, while WWV (as a time base) is recorded on a second channel. Time marks are made on the EU-20B chart manually at the beginning and end of each recording session so that additional time marks can be added during analysis.

From the chart of Fig. 3, some conclusions are possible, with the following qualifications:

(1) 93.7 MHz was chosen as an FM reference frequency because it was not occupied in my area, and in the north, east, NE, and SE regions of the country it was well occupied by high-power FM broadcasters. •By plotting the location and coverage areas of stations on this frequency, versus other possible frequencies, it became apparent that this frequency had more territory *covered* with signal than other frequencies I could have chosen.

(2) Many of the stations operating on this frequency did not sign off until after 2 a.m. EST, and returned to the air by 5 a.m. EST, affording me nearly 24-hour coverage.

(3) FM stations on this frequency closely paralleled TV channel 2 and TV channel 7 allocations, which I was also monitoring, affording excellent opportunity for correlation within a single burst over the frequent range 55.25 to 175.25 MHz.

The observations for the 93.7 MHz measurements, in the 41 monitoring periods, were as follows: considerably higher in the 9–10 (a.m. and p.m.) period than in the 5–7 a.m. period. In other words, if a one-hour period (5–6 a.m.) produced 20 pings, 4 bursts, and a single superburst, a sampling of the 9–10 a.m. period for the same date or the 9–10 p.m. period for the evening prior indicates (typically) 5 pings, 5 bursts, and 1 superburst. (The *total* count is *lower*, but the count of *usable* bursts is *by percentage* much higher.)

The same observation can be made for the noon-to-1 p.m. midnight counterperiod. Of all periods in the day, this has proved to be the most uniform. On a day-to-day basis, the counts during these two periods are relatively unchanged (except during shower periods). The ratio of pings to bursts during both of these periods falls into a region around the 5–6 a.m. and 9–10 (a.m./ p.m.) periods.

Briefly, the additional *total count* subpeaks during the day (other than the expected 5–7 a.m. period) can probably be explained by two mechanisms:

The 12–1 periods find the earth's surface directly above the time zones shown in Fig. 4. It is probably that debris particles that escape being drawn into the 5–7 a.m. period are swept in a curved trajectory by the wake of the earth's ionosphere and are caught by the outward extension of the ionosphere (points A and B, Fig. 4). This would suggest that the majority of the particles entering the E layer in this period would follow a west-to-east trajectory, and this would enhance signals to the east (or west) of you with greater frequency than signals to the north or south of you. The bursts and superbursts almost always come

(to my location in Oklahoma) from stations 70–110 degrees from me. (I did not look west during these tests.)

The 9–10 periods are less prone to explanation. Smith offered no explanation, noting only the existence of the increased radar return count.

One of the most plausible theories advanced suggests that particles swept into the 5–7 a.m. time period *at an angle* actually skip (as a flat stone thrown across smooth water) from the upper ionosphere; their speed reduced, they will *precipitate* back under the influence of gravity several time zones hence (see Fig. 4).

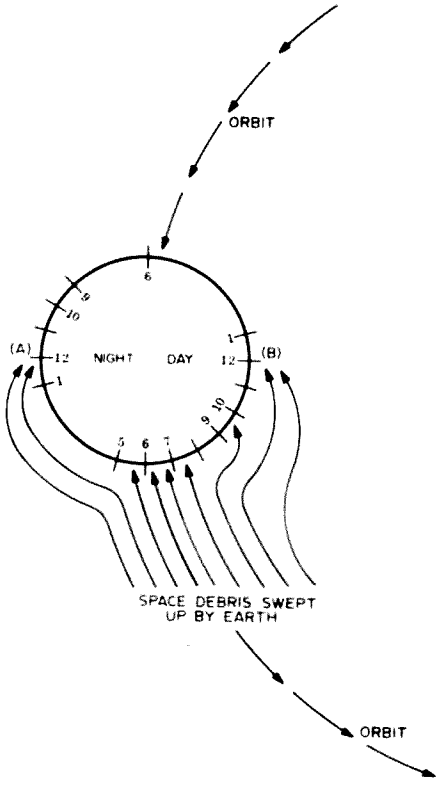

Fig. 4. Path of space debris being intercepted by the earth.

This is borne out to some extent by the observation that at least in the 9–10 a.m. period, there is good correlation on a daily basis between the average total count in the 5–7 a.m. period and the later count in the 9–10 a.m. period for the same day.

The 9–10 p.m. period is more difficult to account for; as Fig. 4 shows, it occurs at a time when the portion of the ionosphere directly over this time zone region is not favorably located for such a skip trajectory, *unless* the skipping is from the midnight period just ahead of it. If such were the case, we would expect a similar situation around 3–4 p.m. as a result of skipping from the noon period. Observations indicate that no such enhancement period exists in the 3–4 p.m. period.

In either case, there is good total-count correlation between the following periods:

(1) 5–7 a.m. and 9–10 a.m. (same date).

(2) 12–1 p.m. and 12–1 a.m. (with 12–1 a.m. time on date following the 12–1 p.m. date).

(3) 9–10 p.m. *seems* to correlate with *both* 5–7 a.m. (5–7 a.m. following) and the midnight period (immediately following); but in both cases the correlation is not good enough to be substantiated.

For directions, the 5–7 a.m. time slot is random. East–west paths propagate just as well as north–south paths.

The 12–1 periods favor basically east–west paths.

The 9–10 periods *seem* skewed in favor of SW–NE paths, in the sense that the *perpendicular* paths (NW–SE) are noticeably poor in these time slots.

Simultaneous Monitoring - 55.25, 93.7, and 175.25 MHz

With relatively similar systems on each of the three frequencies, when the same burst produced propagation on two or more frequencies at the same time, the meteor-propagated signal appeared *first* at the highest frequency affected in 90% of the cases. In other words, if there was propagation at both FM and channel 2, the burst reception appeared first on FM, and was followed by TV up to a full second later (typically just under a second). And if a burst affected all three frequencies, it *always* appeared on 175.25 MHz first, followed up to a second later by the appearance on FM and then up to a second later by the propagation of channel 2 (55.25 MHz). This was directly contrary to

everything we have been led to believe about ionospheric propagation: skip that starts at the top end and works down!

As is often the case with a basic discovery about any physical phenomenon, I was being told something – something very important about the mechanics of the actual formation of an ionized meteor column and the refraction that takes place within the column.

As long as the meteorite particle remains intact its trajectory is marked by an ionized trail spreading behind it.

From the analysis of several hundred recordings of bursts, these factors become apparent:

- At 175.25 MHz, the most intense signals come at the beginning of the burst (Fig. 6), with a trailing off behind the initial peak.

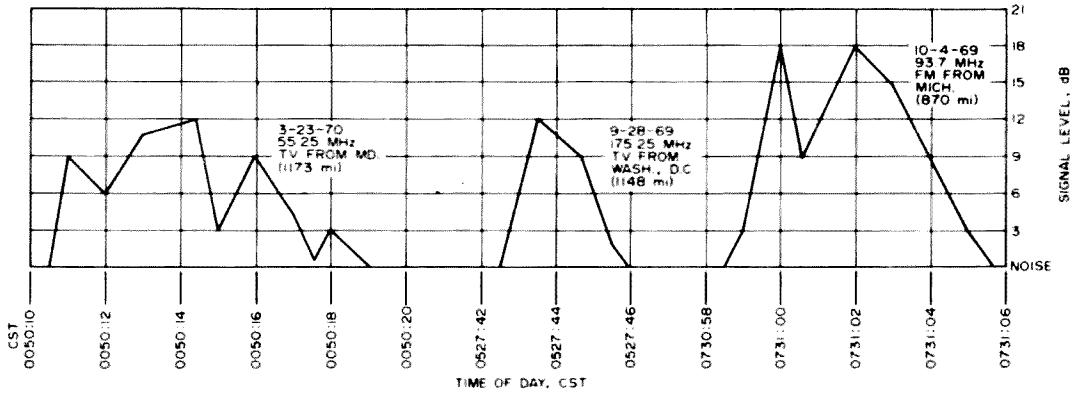

Fig. 6. These curves show the typical duration of meteoric signal reflection. Note the correlation between duration of activity and frequency of occurrence.

Let's look at the mechanics of a meteor-ionized cone formation, in Fig. 5. Here we see that the diameter of the ionized "cone" trail left behind the meteor trajectory is smallest at the particle itself, but it flares outward behind the particle much in the way a speedboat wake flares.

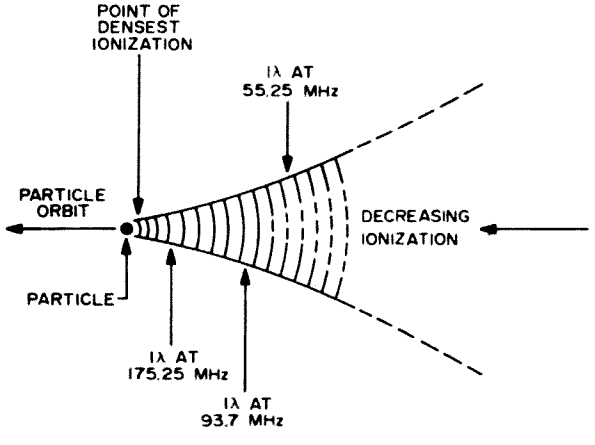

Fig. 5. Bursts are noticed on the higher frequencies first. This could be attributable to the conical makeup of the ionized trail of the meteoric particles.

- At 93.7 MHz, there is often a double-humped initial-signal peak, followed by a depression, followed by a second equally strong peak (Fig. 6).
- At 55.25 MHz, the initial peak is often not the strongest one (although the variation in patterns is greatest at this lowest of observed frequencies).

The intensity of the electron density is going to be greatest in the region *directly* behind the particles (Fig. 5). The amount of ionized material present is most concentrated at this point, dispersing over a wider area as the cone flares.

On the assumption that the density is sufficent to cause signal refraction at 175.25 MHz, refraction will begin to occur only when the 175.25 MHz signal encounters a region within the cone where the cone's flare is at least one wavelength wide (and the electron density at that point in the flare is sufficent to support 175.25 MHz propagation). Because the total *length* of the intense portion of the ionized column is generally short, this point occurs before the conic region has

flared to a sufficent width to propagate the lower frequencies. And the same is true with the 55.25 MHz signal: the cone has flared to a sufficient (one wavelength) width at 93.7 MHz before it has flared to a one wavelength width at 55.25 MHz. (Note that width of the cone and length of the cone can be interchanged here with no basic change in the postulation.)

Keep in mind that maximum frequency propagated is directly related to electron density within the conic area, and that electron density is in turn a function of particle size, speed, and the level within the E layer that the particle ignites.

As Fig. 7 shows, the total burst length, for a burst affecting all three of the monitor frequencies employed here, is pretty much textbook. The highest frequency starts and stops first (lasting the shortest total time); the median frequency starts and stops second and lasts the median amount of time; and the lowest frequency starts last, lasts longest, and quits last.

For the 144 MHz meteor DX'er, this plainly suggests that a whole new school of operating techniques is in order, built around a crystal-controlled converter and a channel 7 (or 8 or 9) TV yagi, using the appearance of bursts at these frequencies as the tipoff to an "opening."

Finally, it should be reported that the frequency of bursts between 55.25, 93.7, and 175.25 MHz drops off substantially, as would be expected, as we go higher in frequency. This dropoff in total count (pings, bursts, superbursts) is about what you would expect, and is representative of both shower and nonshower periods:

From hundreds of hours of substantiative observations it appears the average meteor refraction noted at 55.25 MHz is also found up to 93.7 MHz. At some point between 93.7 and 175.25, the average-burst MUF peaks out and does not reach the highest of the three frequencies.

The author would be interested in hearing from others who have studied or would like to study other aspects of meteor propagation.

... W5KHT ■

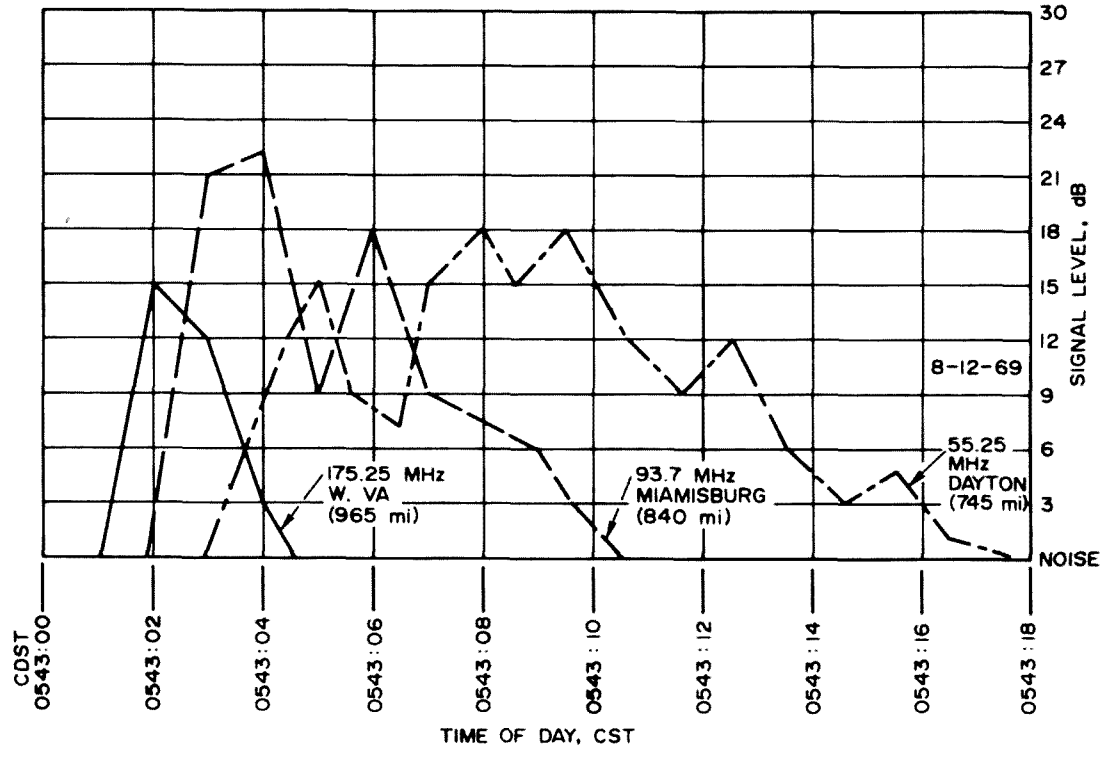

Fig. 7. This composite graph shows burst activity on three frequencies. Note that the highest frequency occurs first, lowest frequency starts last but stays longest.

RADIO BOOKSHOP

FM ANTHOLOGY **$4.95**

Reprints from the FM Bulletin (Feb 67–Feb 68) including the new regs for 150 MHz marine two-way communications, mobile noise suppression techniques, a direction-finding antenna for 146.94 MHz, four transistor crystal controlled converter for 2m FM, three oscillators for tuning up FM receivers, inexpensive preamp for 2m and 6m, design info on antenna matching, discussion of repeater proposals before the FCC, description and details on Baltimore repeater WA3DZD, first five chapters of the infamous Chronicles of 76, a simple TVI eliminator, converting the GE mobile supply to ac operation, community public service, good and bad points of popular surplus 450 equipment, description of W6FNO repeater, using different modes in a repeater control mobile, how frequent should a repeater ID be?, using 2m FM between planes, multiple repeater power outputs, plans and circuit for a hand transceiver, how about a cross country 2m FM net?, mobile telephone setup using a 450 repeater, description of Buffalo repeater, 12 foot omnidirectional antenna a la Comprod and Prodelin, plans for encoder and decoder, SAROC goings on (ahem!), power amplifier for home builder, new telephone regulations for attachments, etc.

THE BEST OF FM **$4.95**

A huge selection of the best technical and construction articles from the FM Journal including data on the formation of a repeater group, licensing a repeater, transistor switching for receivers, 450 MHz gain antennas, adjusting deviation without test equipment, narrowband vs wideband, crystal production from raw quartz through final inspection, transistors over vibrators for mobile, satire on the 41V, eliminating tubes in early hybrid uand units, transistor preamp for mikes, frequency division and multiplexing in repeater control, adjacent repeater problems, multifrequency for the GE, ac supply for the H23 handie-talkie, narrowbanding the Pre-Prog 450 units, converting 456 Prog Line Telephone mobiles for ham use, improving the Gonset FM Communicator, improving 450 Pre–Prog receivers, Wichita repeater, AREC net and public service, quickie T-power and whine filter, logic elements for touchtone decoding, FM vs other modes, squelch for Motorola Pager, instructions for repeater owners, priority inputs for a repeater, four freq for Pre-Prog, 6-Freq osc for 80D and 140D, FM clinic, FM takes over AM, checking crystal ovens, ni-cad charger, mobile hints, and etc.

ATLAS OF FM REPEATERS **$1.50**

Listing, by state and city, of all repeaters, both open and closed, in the world, complete with coverage maps of many of the major repeaters. Maps are included showing the states and counties, with the areas of repeaters indicated.

REPEATER BULLETIN $2.00 YR

Monthly bulletin of news and activities of the New England Repeater Groups. Lots of opinions, controversy, reports, even technical articles and think pieces. This bulletin is available free to all amateurs living in the New England states who are active on 2m FM. Outside of this area the subscription price is $2 per year. Issue number one was January 1972.

The Bulletin is the place where the mass of FM information is published that doesn't make it into 73 because there just isn't enough room. It runs about 24 pages per month (8½ x 11).

If you are interested in a subscription send your name, call, address, including zip, a list of the FM equipment you are using, the repeaters you use, and any repeater clubs or other amateur radio clubs that you are a member of.

108 QUESTIONS AND ANSWERS **$1.95**

Discussions of transmitting, receiving, antennas, power and audio measurement devices, etc. Circuits, gadgets, small construction projects, profusely illustrated. A wealth of interesting information and reading. Cheap, too, considering.

DX HANDBOOK **$2.95**

How to work-DX, how to get QSLs, country lists, award lists, postage lists QSL bureaus, maps of the World, North America, Caribbean, South America, Africa, etc. Great circle maps centered on major U.S. cities, bearing charts for beam headings for major cities, how to go on your own DXpedition, and much, much more. This is the biggest selling DX Handbook ever published, written by 73's editor-publisher who has DXed from nearly 100 countries. This book includes a wall sized DX map of the world, itself worth the price of the book.

ATV ANTHOLOGY **$2.95**

Invaluable book if you are interested in amateur television. This book contains reprints of the most important material from the now defunct ATV Bulletin.

73 TRANSISTOR CIRCUITS **$.95**

Audio amplifiers, preamplifiers, clippers, filters, modulators, receiver bfo, AGC, squelch, tuned audio amplifier, crystal filters, super-regen, 2m preamp, 220 MHz preamp, oscillators, variable crystal oscillator, UHF oscillator, 10m transmitter, 6m transmitter, 2m transmitter, signal tracer, 1 kHz and 100 kHz calibrators, sweep frequency generator, sawtooth generator, test equipment of all kinds, stuff. Fun. Inexpensive.

FM REPEATER HANDBOOK **$5.95**

This hardbound book from Howard Sams is not available on the subscription bonus deal. Sorry, because it is one you will want if you intend to set up a repeater.

RADIO BOOKSHOP Peterborough, New Hampshire 03458.

RADIO BOOKSHOP

FM REPEATER CIRCUITS MANUAL **$4.95**
HADRBOUND EDITION **$6.95**

This 300-plus page book has material on basic FM repeaters, national standards for FM repeaters, carrier operated repeaters, tone decoders for repeaters, controlling repeaters with tones, improving repeater intelligibility, minimizing desensitization, solving intermodulation problems, digital identification, the WB6BFM identifier, a computer-optimized digital identifier, WA0ZHT design data, the Curtis identifier, the K6MVH autopatch, the Zero DKU autopatch, the touchtone autopatch, setting up a mobile station encoders for sub-audible, tone burst and whistle-on use, multichannel scanning, RF preamplifiers for repeaters, antennas for 2m FM, collinear gain antenna for repeaters, welding rod groundplane, high gain mobile antenna, poor man's frequency meter, signal generator circuits, RF power measuring, adjusting deviation, pocket sized transmitter and receiver, low cost portable transmitter for repeater use, UHF transmitter, super-regen receiver, repeater zero beater, repeater controller, 10-minute timer, repeater audio mixer, and more!

TRANSISTOR PROJECTS **$2.95**

Crammed with home construction projects such as a complete communications receiver, a converter converter, CW filter and monitor, 10-15-20m FET converter, 40 & 160m converter, 2-6-10m converter, 30 MHz i-f strip, audio bandpass filter, 6m FETs, audio derived AGC, 432 MHz converter, 2m converter, megaphone, 1296 MHz converter, simple 10m receiver, FET preamps for 144 & 432 MHz, noise clipper, SSB transmitter, 6m station, 6m ultra-midget, 160m transmitter, 432 MHz exciter, varactor tripler for 1296 MHz, FET VFO for 80m, VFO for HF and VHF, VHF parametric amplifiers, diode controlled break-in, slide bias modulator, modulating transistor transmitters, FET audio compressor – plus technical and theory material on designing RF power amplifiers, zener diodes, integrated circuits, simplified transistor design for the amateur, CW monitor, RTTY indicator, crystal oscillators and more.

TELEVISION INTERFERENCE **$1.50**

Why suffer with TVI? It is curable and this newest and most complete book will help you get rid of that pesky misery.

DIODE CIRCUITS HANDBOOK **$.95**

There are 115 diode circuits in the handbook, including power supply applications, regulators, ac meter applications, all sorts of receiver detectors (AM-FM-SSB), noise limiters, squelch, AGC, varicap tuning, audio clippers, compressors, FM modulators, RTTY keying, varactor multipliers, field strength meters, wavemeters, noise generators, and many etc. Very enjoyable book. Cheap too.

VHF ANTENNA HANDBOOK **$2.95**

If you are now or ever intend to be active on any of the VHF bands can you really afford not to spend a lousy $2.95 for a complete and detailed book on VHF antennas? You will find descriptions, dimensions, tuning data, and diagrams of all types of antennas in this book. From an instant coathanger antenna to a giant collinear beam, it is all here. Your antenna is the cheapest amplifier you can build. Get this book.

$7.95

RADIO HANDBOOK The book has been nationally advertised at $12.95, however we have a few copies available at this special price as a close-out on the 17th edition. 850 pages of handbook data and construction projects. This is one of the best book bargains you'll find–while it lasts!

DELUXE WORLD ATLAS **Special $9.95**

This is a beautiful Hammond atlas . . . invaluable if you work DX or have any kids. We ran a subscription special using these $20 atlases and had a few left over. Take advantage of this and buy at the wholesale price. While they last only.

73 BINDERS **$4.95**

These are not available as a subscription bonus. But you still need them to make your issues of 73 stand up on the shelf. It also helps keep back issues from getting lost or spilt on. Or into the hands of the Jr Op. The binders are a gorgeous red and come with the nicest set of year stickers you've ever seen. Dress up your shack with these binders.

SIDEBAND LOG BOOKS **$2.00**

Are you tired of using a log book designed back in the 1920's? Try one of these 1972-type logs designed by W2NSD/1. A pad of 125 log sheets, 8½x11, with 20 contacts per page will last you for 2500 contacts. Try this first really modern log sheet.

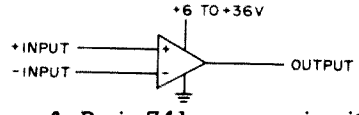
741 OP-AMP COR and TONE DECODER CIRCUITS

The integrated circuit COR and tone decoder circuits shown here are both novel. Both use the 741 type operational amplifier as a combination voltage comparator, high gain amplifier and relay driver. As shown in Fig. 1A, the operational amplifier has two input pins, one output pin, a power supply pin, and a ground pin. Some units also have two "offset-null" pins, but since these are needed only in special cases they are not shown.

The 741 type op-amp is available under different numbers from several manufacturers using different case styles as shown in Fig. 1B and Table I. Obviously the 741 op-amp and all its different versions are very popular, and it is often available for under a dollar.



Of the two inputs, the one labeled + is also often called the non-inverting input, meaning that an input signal on this pin is amplified without being inverted (turned upside down.) The input labeled – is called the inverting input and a signal here is inverted at the output. While this description is useful when the op-amp is used as an ac amplifier, there is a better way of describing the operation at dc.

Since the two inputs have opposite effects on the output, applying the *same* input signal to both input pins will cancel out and produce *no output*. In operational amplifier lingo, this is interpreted as meaning that the output is just halfway between the positive voltage supply and the negative voltage terminal. For instance, if the IC is run at +12V, then the output will be halfway between +12V and ground, or at +6V.

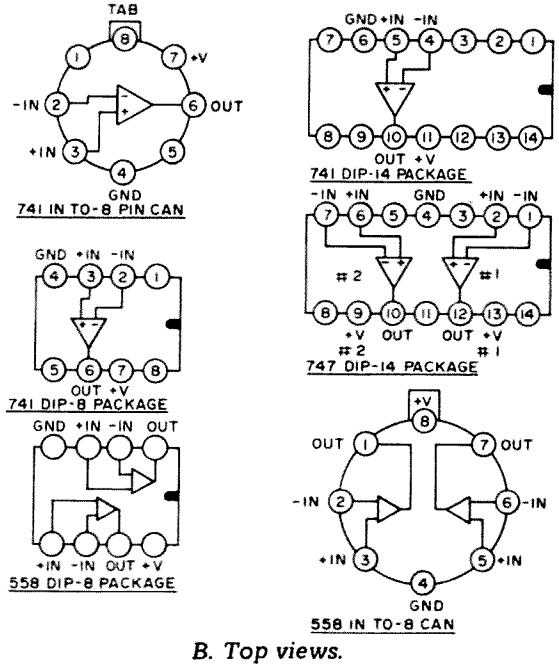


TABLE I

741 type IC Manufacturers and Numbers

Manufacturer	Number	Case & No. Pins
741 Series		
Fairchild	μ5B7741393	TO-8
Fairchild	μ6A7741393	DIP-14

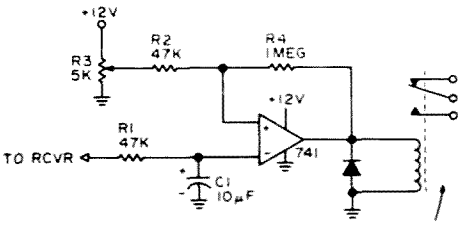

Fig. 2. A COR circuit using the 741 op-amp.

This happens only if the input to both input pins is the same, within a small amount known as the offset. If the plus input is made more positive than the minus input then the output goes more positive. Because of the high gain, only a small difference in inputs is enough to bring the output as high as it can go, within a volt or two of the positive supply voltage.

On the other hand, if the plus input is more negative than the minus input, then the output quickly swings down to within a volt or two of ground. If we connect a relay from the output to ground as in Fig. 2, we can operate that relay by slight changes in the voltages fed to the two op-amp inputs.

The circuit in Fig. 2 is a COR (Carrier Operated Relay) I devised for use with a Vanguard 2m FM receiver. There is a point in this receiver at the output of the audio amplifier which swings from its normal +9V or so down to about +8V when a station is received. I wanted to operate a relay when this voltage dropped.

I simply fed this voltage to the minus input of the op-amp through 47K resistor R1, with capacitor C1 removing any audio. At the same time, the plus input connects through another 47K resistor R2, to the wiper of R3 which provides an adjustable voltage which can be set anywhere between 0V and +12V. For our application we adjust R3 for about 8.5V.

In this application the op-amp acts as a voltage comparator, comparing the voltage from the receiver against the 8.5V reference from R3. With no received signal the receiver provides about 9V, which is higher than the 8.5V reference. Since the minus input to the op-amp is therefore more positive than the plus input, the output voltage is near ground and the relay is off.

As soon as a signal is received, the receiver voltage drops below 8.5V. The plus input is now more positive, and the output goes positive, pulling in the relay.

The circuit would operate quite well without R4, the .1 MΩ resistor from the input back to the plus input, turning on the relay when the input voltage drops below 8.5V and releasing the relay when the input voltage goes back above 8.5V. But occasionally a very weak signal will cause the input voltage to swing back and forth near 8.5V, causing the relay to pull in and out.

To prevent this relay chatter, R4 feeds back a portion of the voltage at the output back to the plus input, increasing the reference voltage fed in from R3 by about 0.2V when the relay is on, and dropping the reference by about 0.2V when the relay is off. This way the relay doesn't go on until the receiver voltage drops below 8.3V. Once on, the relay stays pulled in until the input voltage goes back up to about 8.7V. This hysteresis effect prevents relay chatter on weak signals by changing the circuit into a Schmitt trigger. The dead band can be tightened up by increasing the value of R4, or eliminated by removing R4 entirely.

Another application of the 741 op-amp, again used as a voltage comparator and relay driver, is shown in Fig. 3. Here we have an 1800 Hz tone decoder.

To see how it works, assume first there is no input signal. Resistors R1, R2, and R3 form a voltage divider between +12V and ground, and set up the basic biasing for the circuit. The voltage at the common point between R1 and R2 is about +3.3V. Since this point connects to the minus input of the op-amp through R6 and R5, it provides a

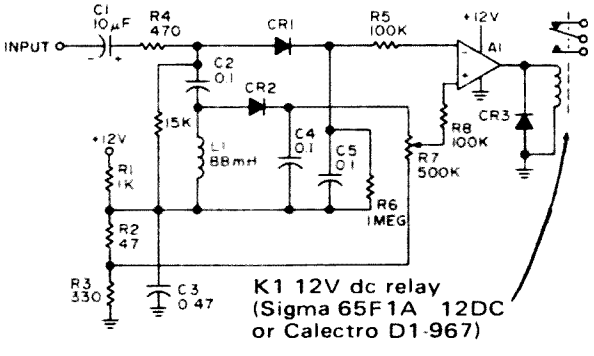

Fig. 3. 1800 Hz decoder.

positive bias to this input. At the same time the voltage at the common point between R2 and R3 is about 0.4V more negative, and this point connects to the plus input of the op-amp through R7 and R8. Since this makes the plus input more negative than the minus input, the output of the op-amp is near ground, and the relay is off (the relay can pull in only if the plus input of the op-amp becomes more positive than the minus input).

Now suppose an audio signal appears at the input terminal. This signal is fed through C1 and R4 to a series tuned circuit consisting of L1 and C2, tuned to 1800 Hz. The audio signal appearing across the *entire* tuned circuit is rectified and filtered by CR1 and C5 and applied to the minus input of the amplifier. Also, the signal across just L1 is tapped off, rectified and filtered by CR2 and C4, and applied to the plus input of the op-amp through level control R7. Both CR1 and CR2 produce positive rectified voltages, but the output from CR2 tries to turn on the amplifier and close the relay, while the output from CR1 tries to keep the relay open.

The tuned circuit does two things at the same time. First, a series tuned circuit at resonance acts as a short circuit, shorting any 1800 Hz signal to ground. Thus it acts as a notch filter, removing 1800 Hz signals from the input to CR1.

But at resonance the current through L1 is quite big, so the voltage across it is high. Thus the tuned circuit selects 1800 Hz signals and sends them to CR2. The total effect of all this is that 1800 Hz signals try to close the relay, while every other signal tries to force the relay open. The relay can only close if there is more 1800 Hz signal than everything else combined. What this really means is that the decoder can't be triggered by noise, speech or even singing – it needs pure 1800 Hz tone.

Potentiometer R7 adjusts the bandwidth, and also affects the sensitivity of the decoder. The proper way to adjust it is to set it for the required bandwidth, and add a separate gain control before the decoder to set sensitivity. Toroid and capacitor tolerances being what they are, you will probably have to try several capacitors to get the

center frequency just right. My C2 capacitance actually measures closer to 0.09 μF than 0.1 μF.

As shown in Table II, the bandwidth is remarkably independent of input level, unlike many decoders which become as broad as a barn when fed with strong signals. If anything, bandwidth becomes a bit smaller at high levels.

The input impedance is about 470Ω and minimum input voltage for reliable operation is between 1 and 2V. Thus the decoder can be bridged across a 4 or 8Ω speaker line, or even across a 500Ω unbalanced line. If the available signal is too low, you can reduce the value of R4, but don't go below about 250Ω. If you need even more sensitivity, use a 3:1 or 10:1 step-up transformer – a filament transformer of the right turns ratio will do just fine.

Don't forget that the decoder won't respond to a tone if it's accompanied by speech or other tones, because anything other than the desired frequency desenses the input. This is a useful feature since it means you won't get false responses to speech, noise, or even music. Under certain conditions, however, you may not want this; for example, in a Touchtone decoder where there are two simultaneous tones.

There are several ways to get around this. The best is to first separate the high Touchtone tones from the low, and thus keep the low group tones from the high group decoders and vice versa. This is the way the telephone company does it, and it works well, since it will detect only one tone in the high group and one in the low at a time.

TABLE II
Bandwidth and Level

	Bandwidth adjusted to		
	100 Hz	200 Hz	400 Hz
Minimum Input Required (rms volts)	1.2	0.8	0.6
Measured bandwidth at			
1V rms input	–	150	390
2V rms input	112	210	430
5V rms input	130	230	430
10V rms input	100	210	420

Another, and far simpler way, is to change the decoder to prevent the desensing by signals outside the passband. This is easily done by connecting the anode of CR2 to the

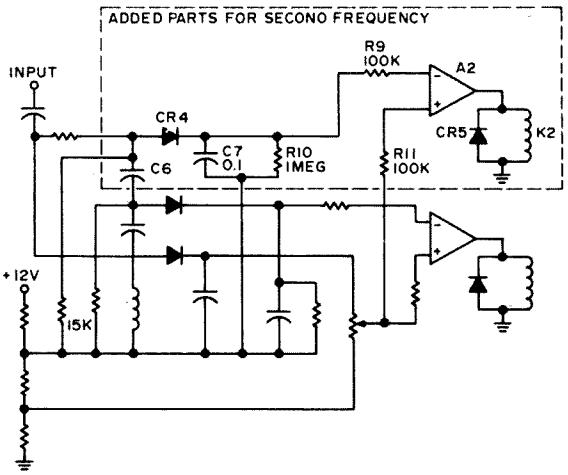

Fig. 4. Two-tone decoder using one toroid.

junction of C1 and R4, instead of to the toroid. This leads to a rather roundabout way of detecting the tone; *any* input signal will try to operate the relay, via CR2 and the plus input of the op-amp. But at the same time, every signal *outside* the passband will try to prevent operation, via CR1 and the minus input. By carefully adjusting R7, we arrange things so only signals *within* the passband succeed.

Along the same lines, Fig. 4 shows how to use *one* toroid to detect *two* tones. If you're careful you might even get more tones out of it, though I haven't tried it. All unlabeled parts in Fig. 4 are the same as in Fig. 3; only parts in the dashed box are added for the second tone.

The values of L1 and C2, in Fig. 3, are chosen to detect the *lower* of the two frequencies, and act as a notch filter at this frequency. Once this is done, C6 is chosen so that the series combination of C2 and C6 resonates with L1 at the upper frequency, to form another notch filter.

In theory, we could add as many of these additional sections as we wanted, and it would be really dandy to have a complete Touchtone decoder with just one toroid, but in practice it won't work. Every added section degrades the Q (and therefore bandwidth) of the whole system. Moreover, the frequency-determining capacitors are shared among several frequencies, and so adjustment becomes really difficult. But it's a cute scheme.

A Simple Solid-State Flying Spot Scanner For Slow-Scan Television

A flying spot scanner is a device which uses a raster on the face of a cathode ray tube to produce high quality television pictures from either photographic slides or prints and drawings. It is usually more economical to build and easier to adjust than a vidicon camera, a factor which makes the flying spot scanner (FSS) an ideal first camera construction project for the newcomer to SSTV. The ease of operation and picture fidelity of a well designed FSS unit also makes it a valuable station accessory even when a vidicon camera is available. Using the FSS to televise most routine picture material reduces the total operating time on the SSTV camera vidicon, an important factor considering the difficulty in obtaining the special 7290 slow-scan vidicons.

The flying spot scanner which I developed to take the load from my own transistorized camera consists of three separate units:

1. The normal station SSTV monitor, which, in addition to displaying the picture output, provides both operating and deflection voltages for the FSS scanning module.

2. An SSTV test generator which supplies a signal to trigger the sweep in both the monitor and scanning module, a sub-carrier oscillator which is modulated by the scanning module output to produce the picture, and a variety of useful test outputs which are completely independent of the scanning module.

3. The scanning module which consists of a scanning CRT whose deflection plates are slaved to those of the monitor CRT, a 931 photomultiplier, and an FET dc amplifier for boosting the photomultiplier output to a suitable level for driving the test generator sub-carrier oscillator.

How it Works

Figure 1 shows a block diagram of the entire system. With no signal from the scanning module, the test generator produces a composite slow-scan signal consisting of one 30 ms vertical sync pulse of 1200 Hz repeated every eight seconds, 5 ms horizontal sync pulses of 1200 Hz at a 15 Hz rate, and a video tone (between sync pulses) of 1500 Hz. The sync pulses cause a square 120 line slow-scan raster to be produced on the monitor screen which is black due to the 1500 Hz video tone. Since the scanning module CRT has its plates slaved to the CRT in the monitor, a raster is produced on this tube as well. Since the scanning CRT is unaffected by

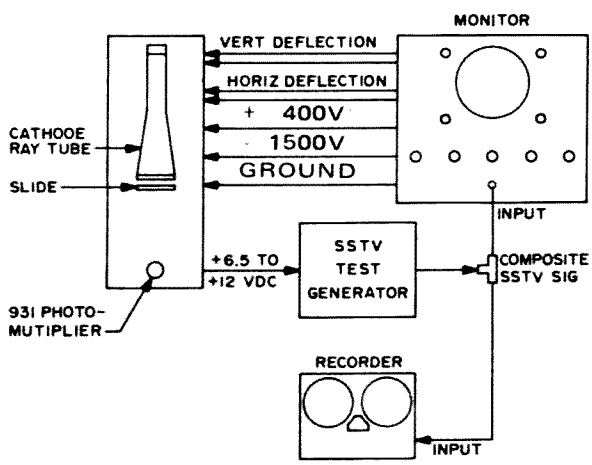

Fig. 1. Block diagram of the solid-state flying spot scanner system.

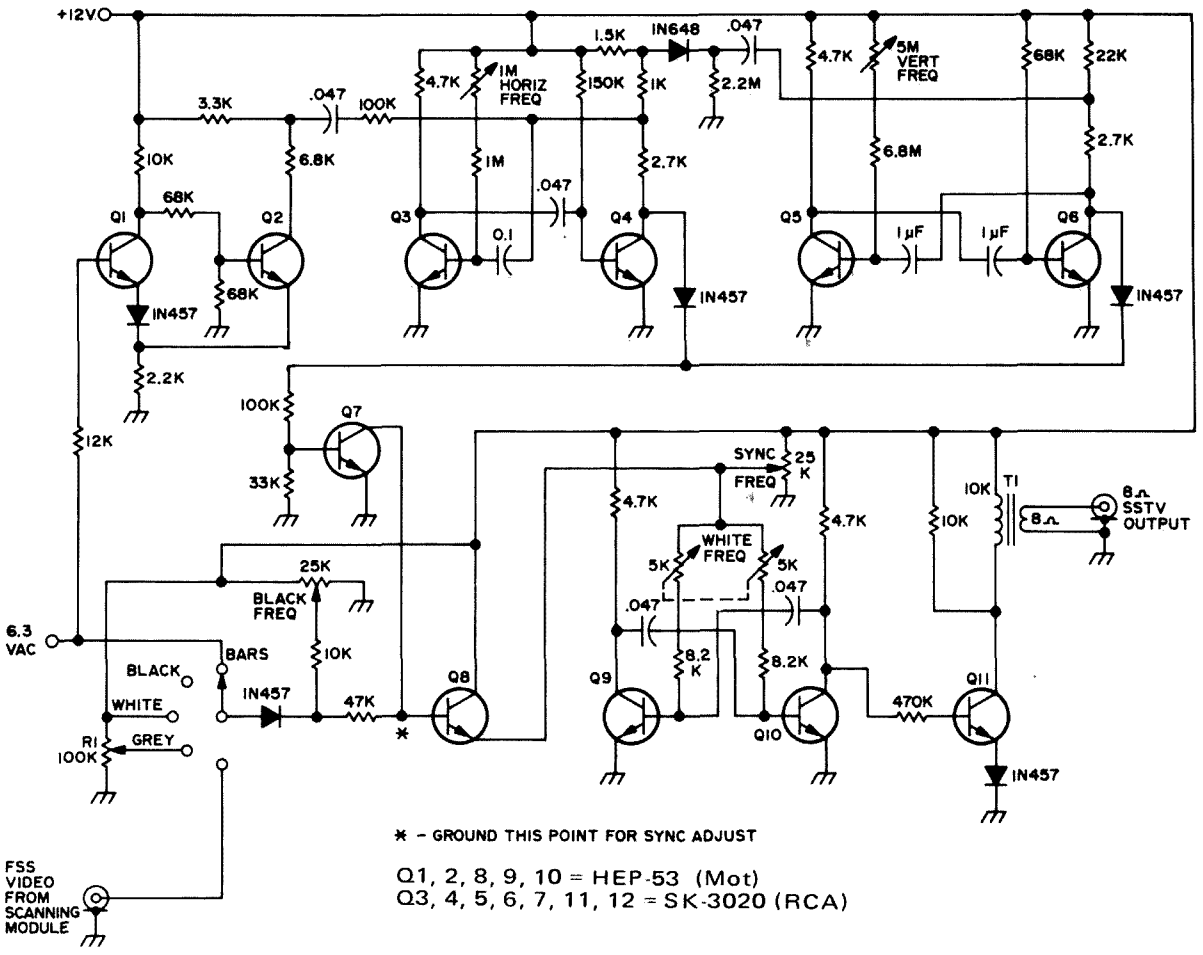

Fig. 2. The SSTV test generator circuit from a circuit described by K7YZZ[1].

the video tone, it can be independently set for a moderately bright raster. A photographic slide is placed over the face of the scanning CRT so that the light from the raster, actually a fast-moving spot of light, must pass through the slide before reaching the 931 photomultiplier tube. The 931 converts the varying light intensity to a minute voltage which is internally amplified by the photomultiplier to a level ranging from −.3V under no illumination (black portions of the picture) to −3.0V under full illumination (white portions of the picture). A single FET is used as a dc amplifier with an adjustable output threshold, producing an output signal ranging from approximately 6.5V (black) to 12.0V (white). This total range, when applied to the test generator, shifts the sub-carrier oscillator from black (1500 Hz) to white (2300 Hz) in a linear fashion, resulting in a replica of the original slide being reproduced on the monitor screen. This video information in no way affects the sync pulses, and since there is no video interconnection between the scanning CRT and the monitor, the picture will remain until the slide is removed from the scanning module CRT face. The brightness control on the scanning module CRT functions as the system contrast control and can be varied to produce the proper light level for good contrast. A T or Y connector is used at the SSTV output jack of the test generator to record the picture output for later playback. The use of the monitor to supply scanning and operating voltages for the scanning CRT and 931 photomultiplier not only reduces cost, but simplifies construction as well.

Construction

Monitor. Very little needs to be done with the monitor to fit it into the system. An auxilliary socket should be installed on the rear apron to make deflection and operating voltages avail-

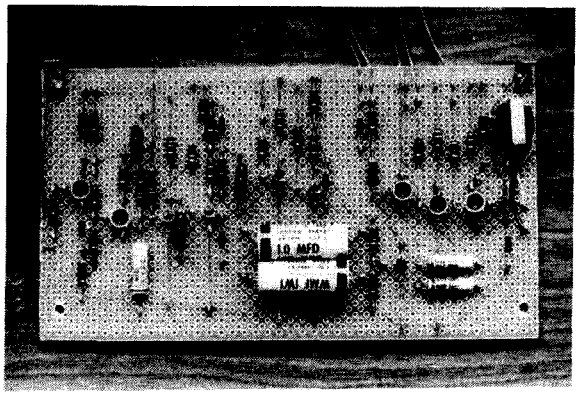

Fig. 3. Photograph of the vector circuit board layout used by the author for the SSTV test generator used in the FSS system.

able. Since the scanning unit should use a CRT that is identical with the one used in the monitor, all required voltages should be available. In my case, I used a six pin Cinch Jones socket for the vertical and horizontal deflection lines (2+2), the 400V required for the astigmatism string, and a ground line. Required high voltages, approximately −1500V and perhaps +1500V (depending on the type of CRT used) are best brought out via standard UHF coax connectors. Care should be taken that the monitor CRT display is completely linear, for the linearity of the finished picture will be governed by this factor since the two CRTs in the system are "slaved" during operation. Vertical non-linearity is the most common type and is usually caused by a faulty discharge capacitor. If necessary, a number of high-quality mylar units should be paralleled to achieve the desired capacity and discharge characteristics.

Test Generator. The heart of the entire system is a solid-state SSTV test generator developed from a circuit described by K7YZZ[1]. The changes incorporated in the circuit have been relatively minor. The transistors originally specified have been replaced by Motorola HEP and RCA SK series general replacement types. These types are usually obtained fairly easily. Some of the RC values have been changed and the "dot-bar" and "sync" test positions have been deleted, while the

FSS video position has been added. The unit was constructed in its own cabinet with an internal power supply so that it can be used independently as an SSTV signal source, if required. Figure 2 shows the schematic, while Figs. 3 and 4 show the circuit board and completed unit. The unit is certainly much larger than required and if miniaturization is your thing, it could certainly be reduced considerably in size. In addition to its function in the FSS system, the generator will also produce a black raster, white raster, a raster with a continuously variable grey level, and a stable bar pattern.

Scanning Module. This module consists of the CRT and its associated control circuits, the 931 photomultiplier, and the FET dc amplifier. A piece of cobalt glass, available in most high school chemistry labs, is positioned between the CRT and 931 to filter out the long-persistence yellow component of the P7 phosphor. Without this precaution, the amplified phototube output would continuously drive the sub-carrier oscillator to white (2300 Hz) due to the persistent yellow glow on the face of the CRT. My module is built on a 6x17x2 in. chassis. A shorter chassis could be used if mirrors were used

Fig. 4. Interior view of the completed SSTV test generator. Front panel controls (not shown) include power, function selector (S1), horizontal frequency, and the grey scale adjust (R1). The remaining pots are mounted on the chassis between the circuit board and the front panel. The rear portion of the chassis contains power supply components. The small circuit board includes bridge rectifier diodes and a zener and regulating transistor.

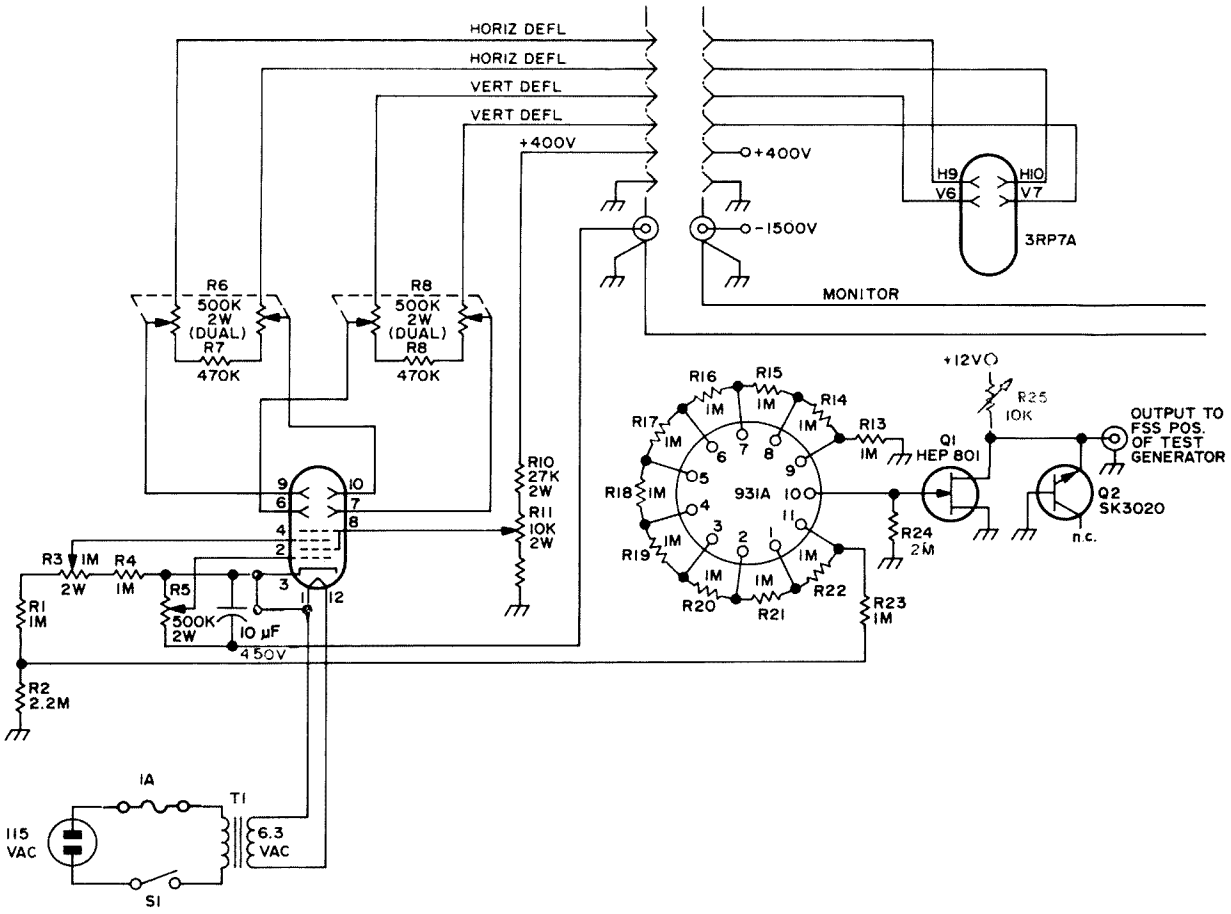

Fig. 5. Scanning module and interconnections with the monitor. The 3RP7A CRT is shown as an example only, for in actual practice the scanning CRT should be of the same type as that used in the monitor. Other CRTs will require different values in the astigmatism and brightness-focus networks and the monitor values should be duplicated. The −1500V is most easily carried via coaxial cable and suitable connectors. If a high positive accelerator voltage is required for the CRT used, it may be carried via a similar cable. Controls are: R6 – Horizontal Size; R8 – Vertical Size; R11–Astigmatism; R5 – Brightness; R3 – Focus; and R25–Dc Level Adjust. T1 is a 6.3V 1.2A filament transformer with secondary windings rated at 2 kV or better.

in the system, but the distance between the CRT face and the photomultiplier should be kept at least 4 or 5 in. if the picture definition is not to be degraded by parallax factors. The CRT should be firmly mounted and some means incorporated to keep the photographic slides pressed firmly against the tube face. Small metal clips may be used or a slide holder can be constructed and attached to the tube face. If elegance or convenience are no object, the slides can simply be taped to the CRT screen! If you plan to use the scanner in a lighted room, a black hood or box assembly can be constructed so that the CRT and the 931 form a light-tight system once the slide is in place. The top of the chassis and the inside of the hood should be painted flat black or faced with black construction paper to eliminate stray reflections.

The schematic of the scanning module and monitor interconnections, Fig. 5, show values in the brightness, focus, and astigmatism networks that are consistent with the 3RP7A used in my own monitor. If your monitor uses another tube, simply substitute equivalent networks from your own monitor circuit. In the event of such a change, be sure to modify the CRT socket connections as required. The 931 requires a negative voltage of some 600 or 700V for proper operation. Alter the relative values of the resistors following the focus pot in your own circuit so that this voltage is available.

High voltage wire should be used where appropriate and the brightness and

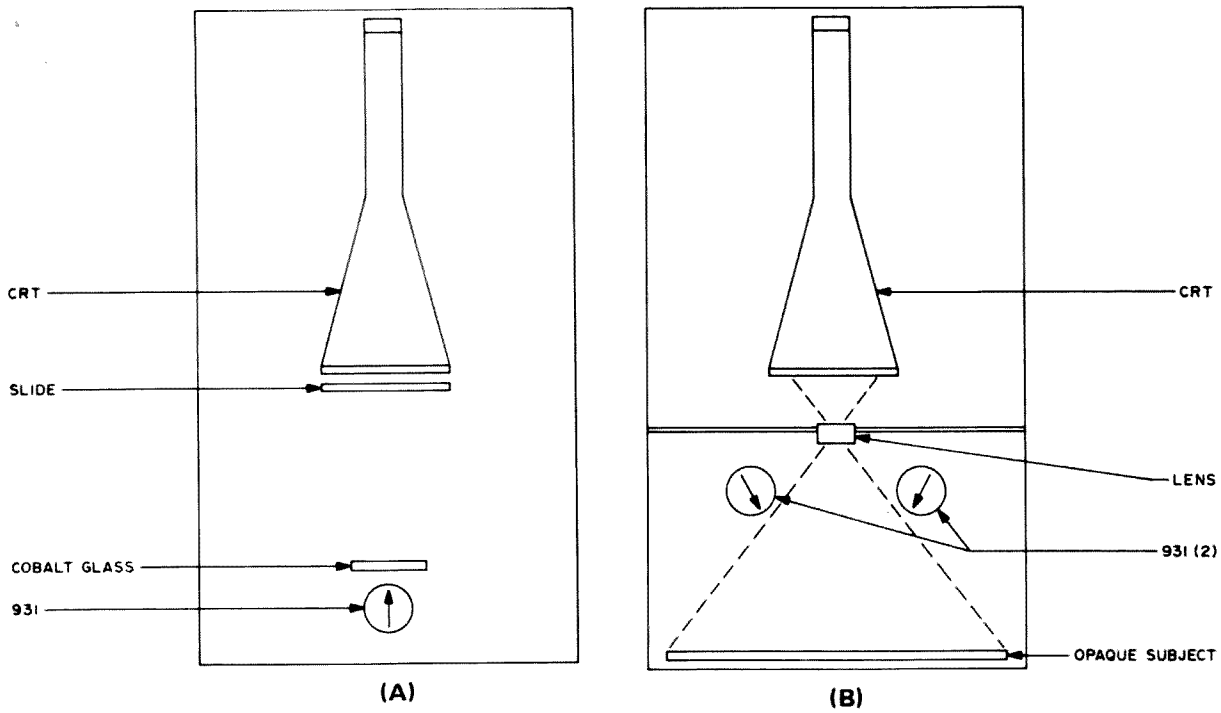

Fig. 6. Diagrams of the mechanical layout for two basic approaches to FSS design. (A) shows the transmitted light system, suitable for photographic slides and other transparencies, used by the author. (B) shows a more complex arrangement, suitable for televising photograph prints and drawings, as used by K7YZZ[2]. The arrows indicate the orientation of the key in the 931 sockets so that the light sensitive area of the tube faces in the proper direction.

focus pots should be *insulated from ground and equipped with insulated shaft extensions.* The focus, astigmatism, and dc output level can be placed anywhere that is convenient as they are rarely adjusted after initial setup. The brightness control is the system contrast control and should be placed for convenient adjustment when the scanner is in operation.

There are actually two options available in constructing the scanning unit. My own unit is built to handle photographic slides and transparencies and the general layout is diagrammed in Fig. 6a. It is also possible to set the scanner up to transmit pictures from photographic prints and drawings. The somewhat more complicated mechanical layout is diagrammed in Fig. 6b. Here a lens is used to focus an image of the scanning raster onto the photographic subject. The light *reflected* from the subject is picked up by two 931 photomultipliers. This approach was used by K7YZZ in his tube FSS circuit[2] and anyone contemplating this approach is urged to consult this article for details of mechanical layout.

Adjustment and Use

The test generator should be aligned first. The generator output should be connected to a frequency counter or some other setup for determining the frequency of the audio output. The base of Q8 should be grounded with a test lead and the sync frequency control adjusted for 1200 Hz output. Remove the

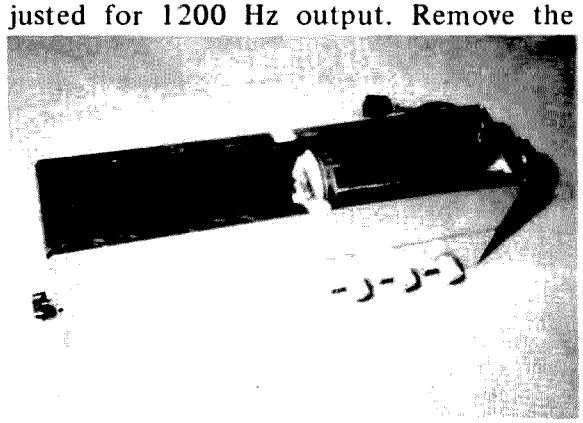

Fig. 7. A photograph of the author's scanning module. The CRT is enclosed in an alloy shield to eliminate the effect of external magnetic fields. The 931 on the far left has been painted black except for the photosensitive "window" while the chassis enclosure has been lined with dark felt. A felt lined cover is placed over the top of the unit after the slide is in place.

test lead and switch S1 to the "black" position, adjusting the black frequency control for 1500 Hz output. Switch S1 to the "white" position and adjust the white frequency control for 2300 Hz output. This series of adjustments should be repeated several times as there is some interaction between the various frequency controls. The generator should then be connected to the monitor and S1 switched to the bars position. The horizontal frequency should be adjusted for a stable display of four vertical white bars and the vertical frequency should be adjusted for an eight sec. frame time. At this point, without plugging the scanning module into the test generator, the following monitor displays should occur at each setting of S1:

BARS – four vertical white bars on a black background.

BLACK – a pure black raster.

WHITE – a pure white raster.

GREY – a raster whose intensity can be varied from black to white using R1.

FSS VIDEO – a black raster.

Turn out all of the room lights or cover the 931 photomultiplier. Plug the video line from the scanning module into the generator and apply power to the scanning unit. The dc level control should be adjusted to the point where the subcarrier output *just* begins to rise above 1500 Hz. Turning on the room lights or removing the cover on the 931 should immediately cause the raster on the monitor to go from black to white. Turn out the room lights and adjust the scanning module brightness, focus, and astigmatism controls for a moderately bright, well-focused raster. The respective size controls should be adjusted for a square raster of a size appropriate for the slides being used. Very small adjustments in centering can be made using the monitor centering controls. Put a slide in place and adjust the scanning module brightness control for the best picture contrast when viewed on the station monitor.

Photographic slides, either color or black and white, may be used directly in the system. Call signs and other printed material can be prepared on clear acetate using dry transfer lettering. "Instant" slides can be made on acetate using india ink, wax marking pencils, or many of the felt tip pens available on the market. Various portions of the slide may be cropped or enlarged, within the resolution limits of the CRT, by changing the size and position of the scanning raster. Figure 8 shows some typical output from the system. Building a system of this sort is certainly one of the easiest and least expensive ways to produce high quality SSTV pictures.

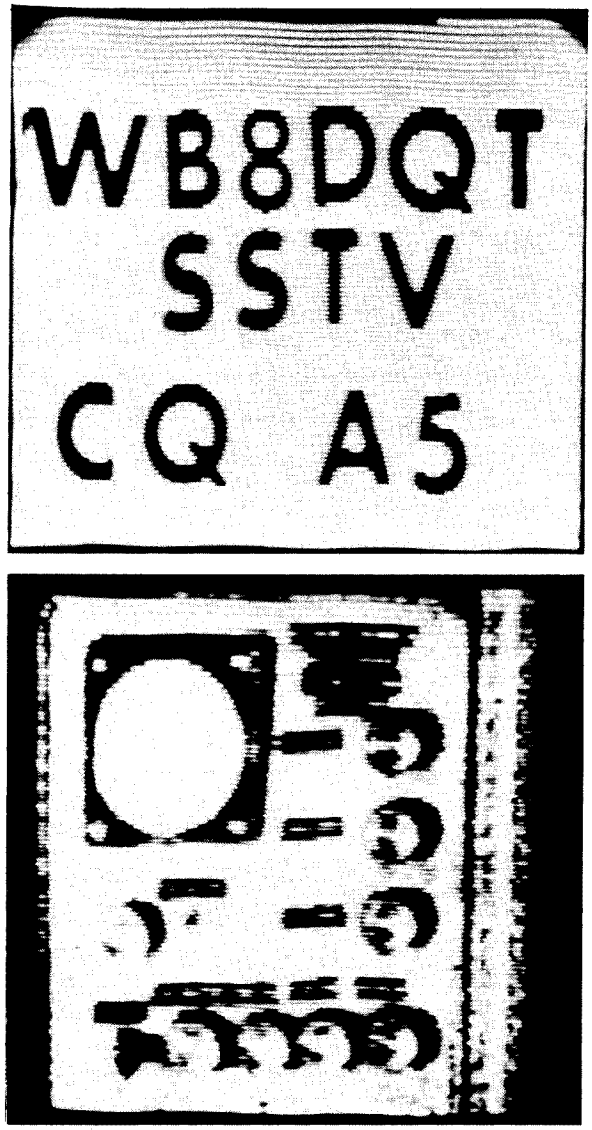

Fig. 8. Typical picture output as viewed on the author's SSTV monitor.

ACTIVE FILTER DESIGN AND USE PART II

Although information concerning active network theory in the form of inductorless filters was published by Linvill in 1954, it is only since the popularity of solid-state devices and miniaturization that renewed research has shown their real potential.

In seeking a starting point for active filter design, we must consider the desired function of the network and its passive LC or RC counterpart. A basic LC low-pass filter can be used as a design prototype for any of the other filter types. Similarly, basic RC networks will be used as design prototypes for active filters. In choosing a network which we hope will produce the desired response, it is important to remember that some designs are more applicable to specific functions than others. For instance, RC ladder networks lend themselves to low and high-pass designs. The RC twin-tee notch configuration functions well as a bandstop or adjacent frequency elimination network, while RC active peaking networks provide the Q for a bandpass response. Where it is necessary to improve the performance of the single network, active sections may be cascaded, much like multiple section LC filters.

Figure 1 shows a third-order active low-pass filter with the three poles being simulated by frequency-dependent capacitors C1, C2, and C3. The resistances R1, R2, and R3 serve to vary the frequency response by altering the gain, impedance, and waveshape. The cutoff frequency f_o for this filter is given by:

$$f_o = \frac{1}{2\pi R C}$$

The RC product in the above formula incorporates the sum of the individual values of resistances and capacitances in the network. The circuit of Fig. 1 is a unity gain amplifier when operated under optimum conditions. In addition, the gain will be primarily dependent upon the value of R, which is always in series with the signal flow. Moreover, the value of R is, to a great

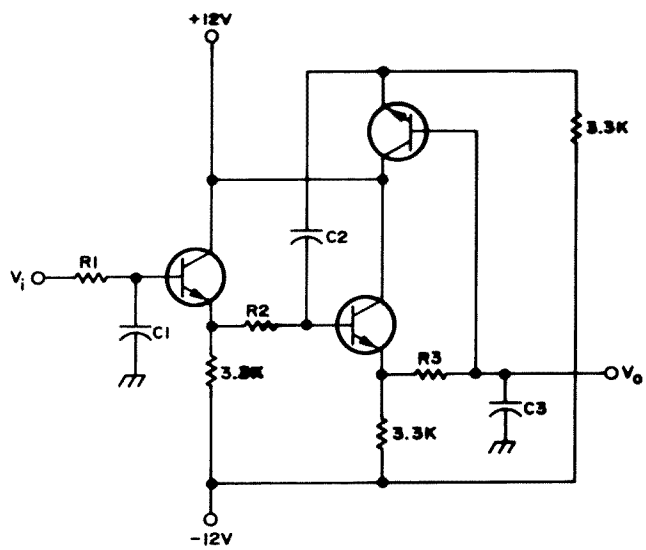

Fig. 1. Active low-pass filter.

Table I

	$C_{1,2,3}$	$R_{1,2,3,}$	Insertion Loss	f_o	-3 dB	-10 dB	-20 dB
A	.001	620	8 dB	28 kHz	100 kHz	175 kHz	220 kHz
B	.001	1 k	7 dB	17 kHz	75 kHz	140 kHz	300 kHz
C	560 pF	4.7 k	17 dB	7 kHz	50 kHz	90 kHz	160 kHz

extent, dependent on the corresponding value of C. In practical consideration, the cutoff frequency is limited by the required value of €. As the value of C is decreased, and R remains the same, the cutoff frequency is increased. The same is true for the resistor values. Consequently, there is a point where minimum capacitance requires the increase in the value of R to obtain a higher cutoff frequency. This is done at the expense of higher insertion loss or lower gain.

The value of the emitter resistors was chosen as optimum for maximum gain of the MPS 6520 transistors. Table I gives the results of trying different values of R and C in the low-pass filter circuit. Figure 2 shows the plotted frequency response for the values of Table I. From these results, it is obvious that two major areas require improvement. Of greatest importance is the lack of a sharp cutoff at the −3 dB point. We should also expect a minimum of 15 dB attenuation per octave. High insertion loss also affects the overall response, flattening the peaks and decreasing the gain. A reasonable improvement should be expected if we could design a similar filter with less insertion loss and steeper slope.

Figure 3A shows two cascaded RC networks. When this two-pole network is placed in the signal path, each section (R1C1 or R2C2) exhibits its individual frequency characteristics, which are algebraically added to produce the final filter shape response. In other words, if the network consisting of R1C1 had a rolloff around 1 kHz, and R2C2 extended this cutoff to 2 kHz, we could not expect to obtain a summed cutoff frequency of 3 kHz by cascading the two networks, but the resulting −3 dB point would be closer to 1.5 kHz. Although we may sharpen the response curve at the −3 dB point by cascading the two networks, we will have the problem of high insertion loss and minimum attenuation slope. By separating the two networks, consisting of R1C1 and

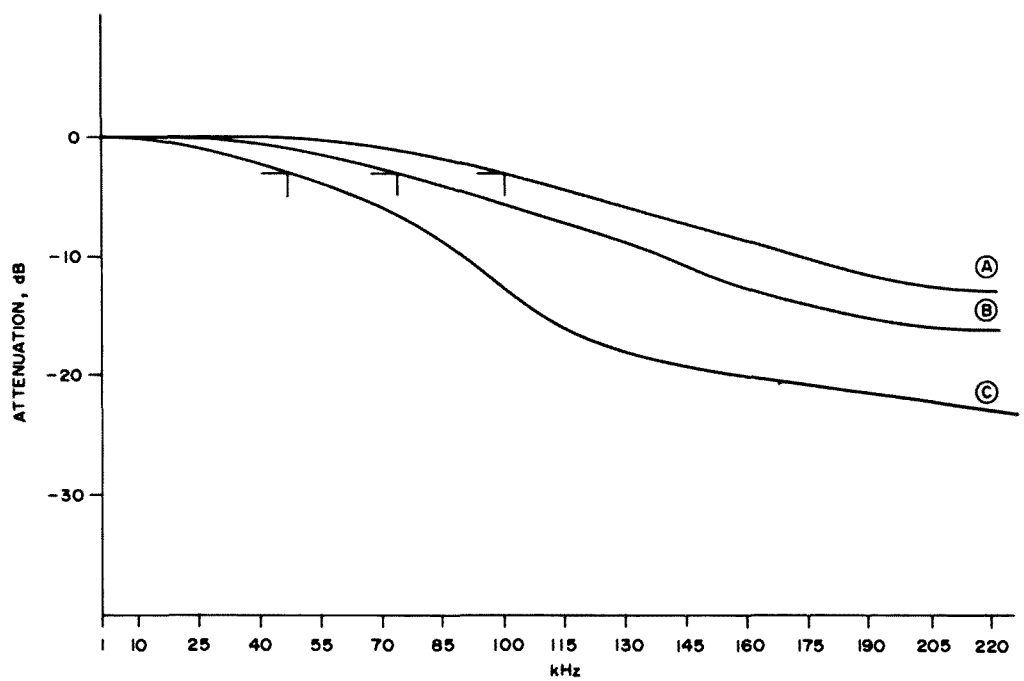

Fig. 2.

R2C2, and utilizing them as input and output circuits of an amplifier, we can lower the network insertion loss and alter the final filter response.

In Fig. 3B, the signal is fed to an amplifier (A) from which a feedback line (beta) is taken to be reinserted at the RC network. Figure 4 shows the results of variations of network component ratios and circuit design for a low-pass filter. The damping factor d is a measure of the two-pole response at the −3 dB point. Its value is dependent upon the network Q. The steeper the response curve, the greater the Q and the smaller d must be:

$$Q = \frac{1}{d}$$

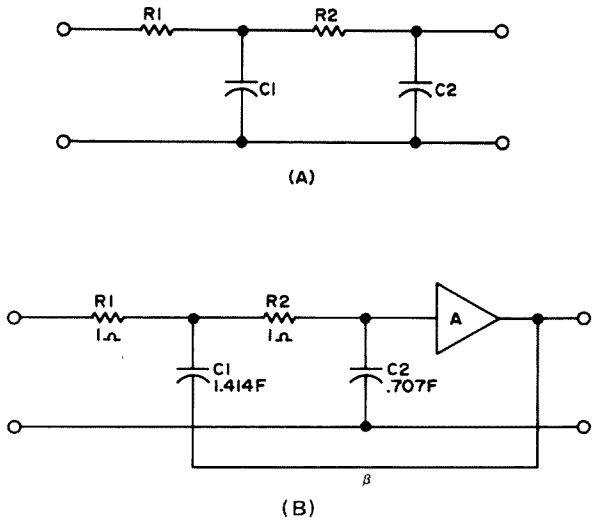

Fig. 3. Normalized lowpass filter.

Without feedback, Fig. 4 shows that the best response we can expect is where parameter d is equal to one. Such a curve would be the result of a passive RC network with a maximum gain of unity, as shown in Fig. 3A, or the active network of Fig. 1. By utilizing a feedback loop, the slope can be modified to the curves showing d equal to less than one. If an amplifier is incorporated before the feedback loop, d becomes a function of gain and feedback. In this case, the frequency characteristics take on the shape of the curve where d is equal to much less than one.

Figure 5 shows an active network which can be designed to provide any value of d for a given corner frequency ω_o. Transistor Q1 is an emitter follower stage biased for maximum gain (unity) and stable operation. The signal is direct-coupled to the emitter of Q2, and from the collector of the amplifier to the output through the emitter follower Q3. This arrangement allows transistor impedances to be matched and provides a gain (k) greater than unity, although naturally less than with a common emitter amplifier. Due to the required configuration of the filter section, the signal source appears as a constant-current generator. Therefore, the signal baselines, normally considered as zero, may be above the dc zero reference value. This possibility

makes biasing of Q1 different from normal capacitor-coupled configurations. The base must remain positive, with respect to the emitter, for the entire swing of the input signal, regardless of where the signal baseline may be. Failure to provide correct biasing will cause clipping of the negative portion of the waveform, or when bias is too low to allow the transistor to conduct, the scope display will appear as though there is a loose connection or a ground lead missing.

The input impedance of the active filter is high while the output impedance is low (approximately 600Ω), thus lending itself to incorporation into transistor circuitry. Power supply leads should be decoupled to prevent signal loops which might cause shape distortion or oscillation.

The shape of the frequency characteristic is mainly dependent on the ratio of R1C1 to R2C2 and the amount of feedback voltage determined by the ratio of R10 to R11. The gain k of the amplifier is set by the ratio of the resistors R8 and R9. To achieve good slope attenuation, the response of the active section of the filter must be combined with that of the passive section R1C1. This requires a βk factor of greater magnitude than would be necessary for the active filter without the passive section.

In designing the RC sections, R1 and R2 should be relatively low in value for good temperature stability. The ratio of C1 to C2 can be considered to be 10 for a good starting point. By the use of impedance and frequency scaling, we can obtain values for R1C1 and R2C2. These values will not be final filter values since changing R or C may be necessary to obtain the desired response shape in conjunction with feedback and gain. Therefore, a change in R requires a change in the value of the corresponding C. In Fig. 3B, values have been assigned to the components to produce a normalized active filter network for 1 radian per second. These prototype values are for two-pole Butterworth filters. To determine the value of C, we utilize the frequency scaling formula:

$$C' = \frac{C}{2\pi f_c}$$

In this equation, C′ indicates value after frequency scaling.

For a Butterworth response with a cutoff frequency of 2.5 kHz (−3 dB point), we obtain for C1:

$$C'1 = \frac{1.414}{6.28(2.5\times10^{3})}$$
$$= 0.09\times10^{-3}\,F = 90\,\mu F$$

For C2:

$$C'2 = \frac{.707}{6.28(2.5\times10^{3})}$$
$$= 0.045\times10^{-3}\,F = 45\,\mu F$$

To achieve convenient values of capacitance and impedance, we need only use a constant value applied to the components of each section. The constant need not be the same for each section. Using the chosen constant to divide the capacitance and

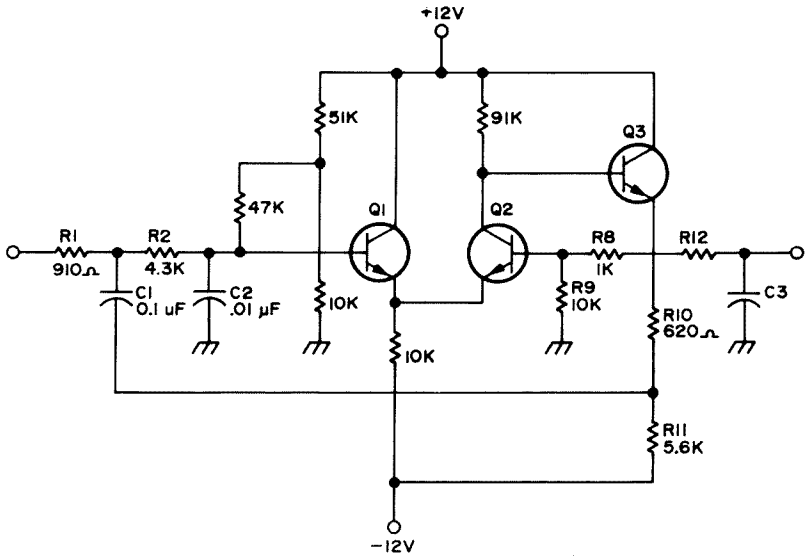

Fig. 5. Active low-pass filter.

multiply the resistance prototype values, a trial RC network is produced. Utilizing 900 as the constant for the R1C1 section, we obtain:

$$C1 = \frac{90}{900} = 0.1\ \mu F$$

$$R1 = 900(1) = 900\Omega$$

If we choose 1000 as the constant for the R2C2 section:

$$C2 = \frac{45}{1000} = 0.045\ \mu F$$

$$R2 = 1000(1) = 1\ k\Omega$$

Figure 6 shows response curves for the above computed RC values with gain varying resistors R8 and R9 having values of 1 kΩ and 10 kΩ respectively. The curves show the effect of decreasing or eliminating R10, thus increasing feedback β. From Fig. 6, the factor βk must be increased and the cutoff frequency/attenuation slope must be decreased while maintaining a passband within ±1 dB. Figure 5 shows the final design and Fig. 7 the response curve for the active low-pass filter. To obtain the 10:1 ratio of C1:C2, and decrease the cutoff frequency/attenuation slope, the values of C2 and R2 were changed to 0.01 μF and 4.3 kΩ. The passive section consisting of R12 and C3 in Fig. 5 may be utilized at very low frequencies to flatten the passband. Values for these components can be computed by the formula:

$$f_c = \frac{1}{2\pi R C}$$

At higher frequencies (above 1 kHz) the passband should be flat within ±1 dB

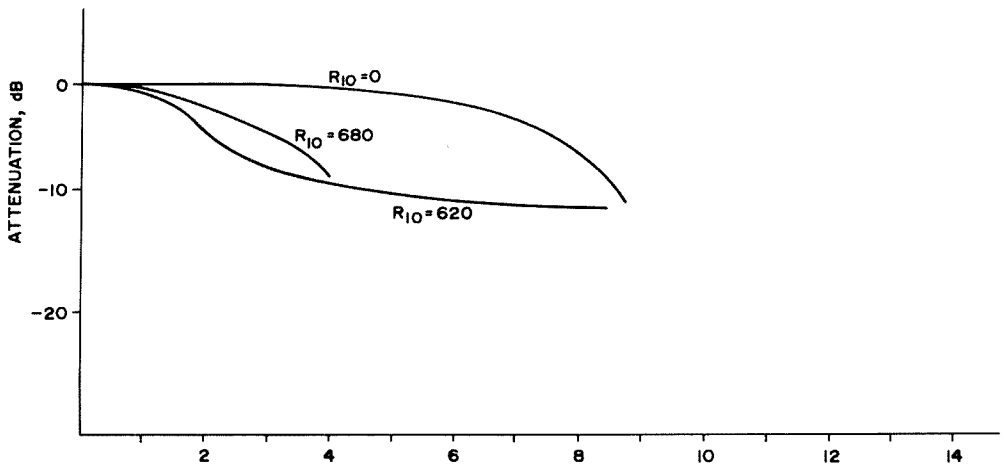

Fig. 6.

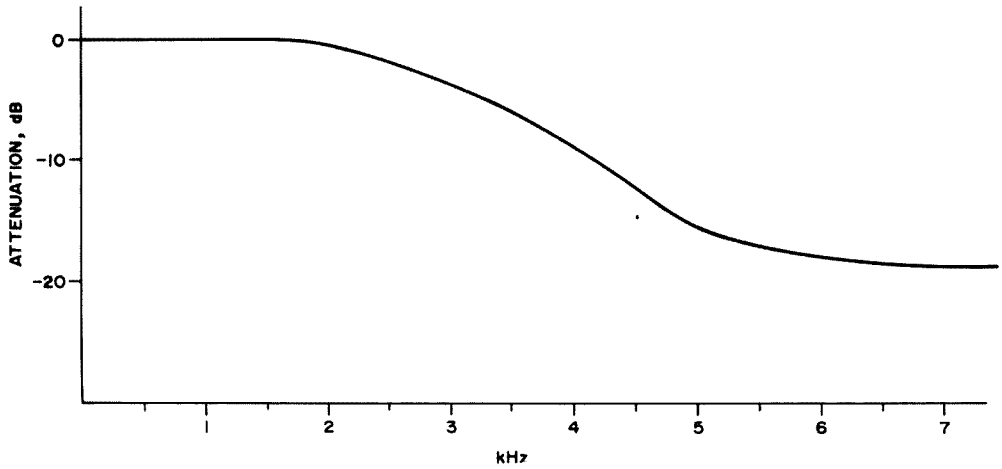

Fig. 7. Low-pass response.

without the added passive section. Consequently, the active network can exhibit gain without these components.

By changing the positions of the LC components, and finding the reciprocal values, a low-pass filter became a high-pass network. Similarly, as shown in Fig. 8, the same principle can be applied to RC active filters. The branches which originally contained capacitors are now made up of resistors with the normalized value of the reciprocal of the constant values of 1.414 and 0.707 originally assigned the capacitors in the low-pass network. In the new high-pass filter the original resistors are replaced by capacitors, also normalized for a cutoff frequency of 1 radian per second.

Frequency scaling to determine the values of CI and C2 at a 3 dB cutoff frequency gives:

$$C'1,2 = \frac{C}{2\pi f_c}$$

$$= \frac{1}{6.28(2.5\text{x}10^3)}$$

$$= 63.7\ \mu F$$

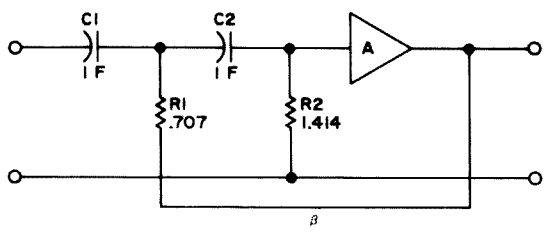

Fig. 8. Normalized high-pass filter.

Impedance scaling is similar to the low-pass procedure where the capacitor values are divided by a constant value and the resistors are multiplied by the same figure. The constant may be different for each section. If we attempt to begin with a 10:1 ratio for the parallel branches, and choose values of 100 for R1 and 10 for R2, impedance scaling provides:

$$R1 = 0.707(141.4) = 100\Omega \qquad R2 = 1.414(7.14) = 10\Omega$$

$$C1 = \frac{63.7}{141.4} = 0.45\ \mu F \qquad C2 = \frac{63.7}{7.14} = 8.92\ \mu F$$

The active high-pass network functions as a voltage amplifier, thus requiring different biasing than the low-pass filter. By utilizing R2 as a bias resistor in addition to

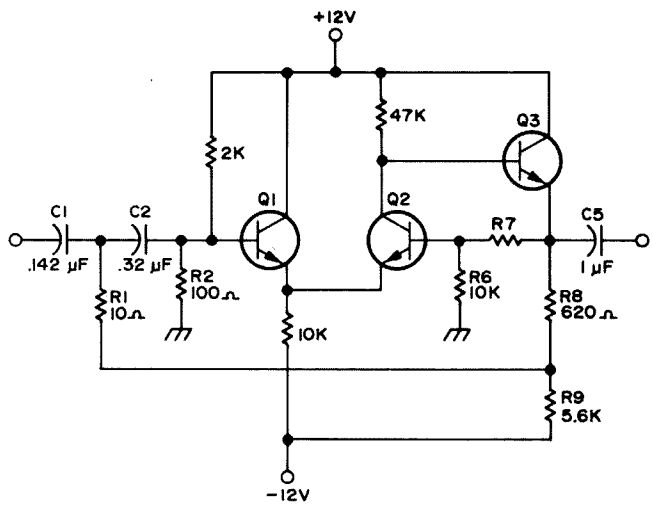

Fig. 9. Active high-pass filter.

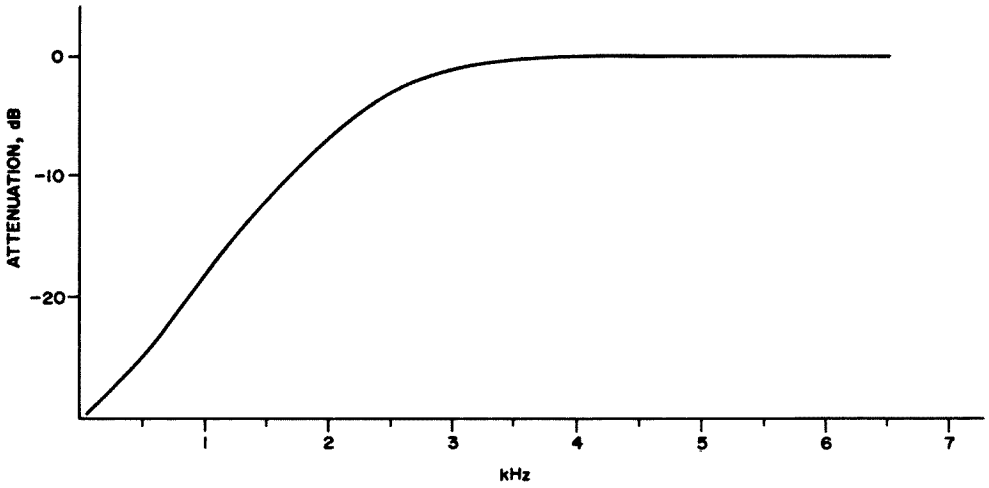

Fig. 10. High-pass response.

its function in the passive section, design is simplified. To increase the bias on Q1, R2 must be greater than 10Ω. Exchanging the positions of R1 and R2 provides the necessary base bias on Q1, maintains a 10:1 ratio in the parallel filter branches, but requires recomputation of C1 and C2:

$$R1 = 0.707(14.1) = 10\Omega \qquad R2 = 1.414(71.4) = 100\Omega$$

$$C1 = \frac{63.7}{14.1} = 4.5\ \mu F \qquad C2 = \frac{63.7}{71.4} = 0.89\ \mu F$$

As in the active low-pass filter, the ratio of R2C2 in conjunction with the feedback components R8 and R9 determine the response shape of the high-pass filter. The final values of these components, obtained by altering the ratios, is shown in Fig. 9. The response shape of the active RC high-pass filter is plotted in Fig. 10.

To obtain bandpass or bandstop responses we need only combine the characteristics of the low-pass and high-pass filters. In Fig. 11A, the combined re-

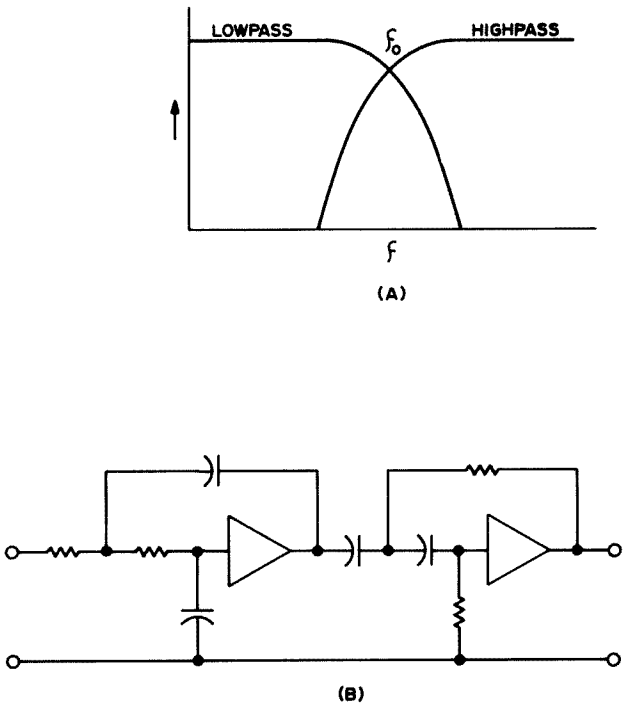

Fig. 11. Active bandpass scheme.

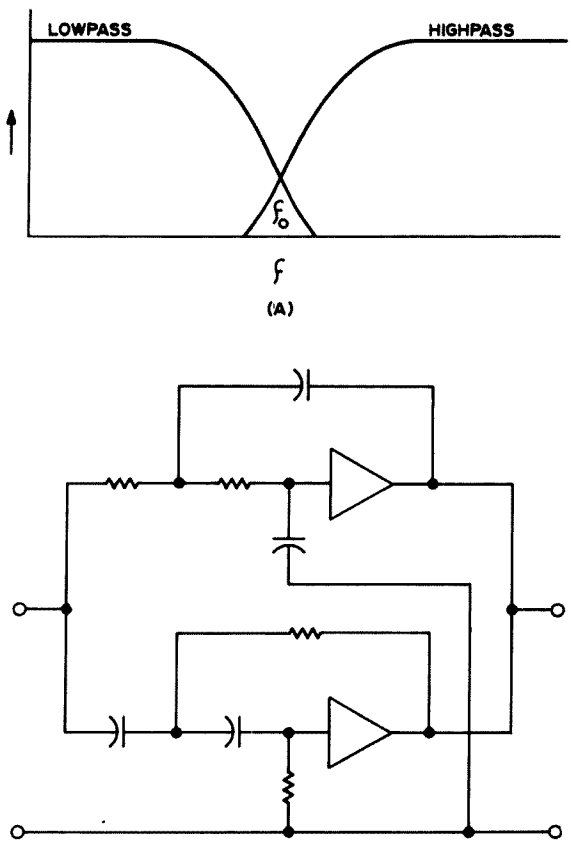

Fig. 12. Active bandstop scheme.

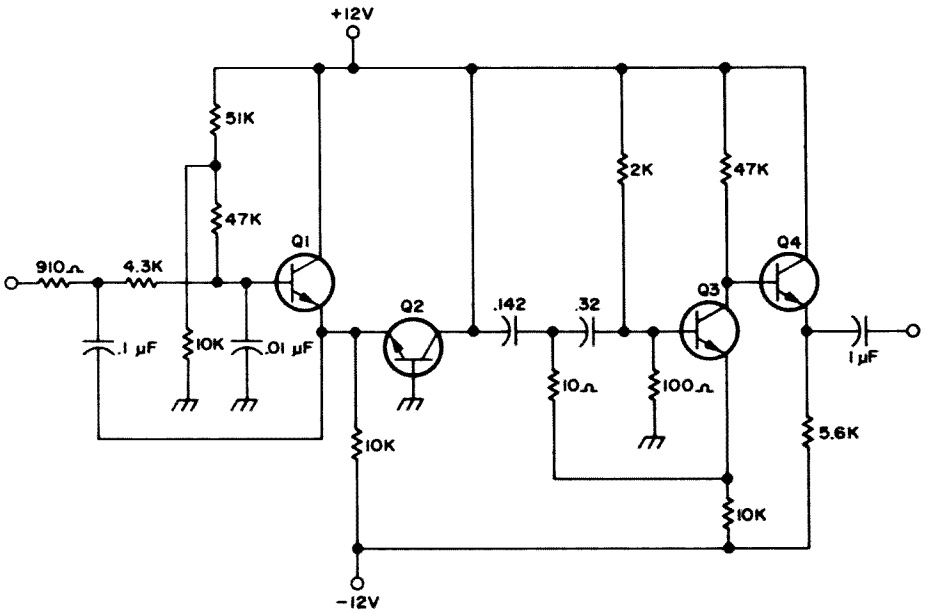

Fig. 13. Active bandpass filter.

sponses of a cascaded low-pass and high-pass filter, as shown in Fig. 11B, are displayed as simple curves superimposed one on the other to form a bandpass shape. To assure the desired response and maintain symmetry, some sort of peaking is required at f_0. This is normally a function of Q. Algebraically summing these two networks will produce a bandstop response as shown in Fig. 12. Normalized values for these prototypes are the same as given in the two previous designs.

In Fig. 13 we have cascaded a low-pass and high-pass filter to obtain a bandpass response. The passive filter component values are the same as used with the individual low-pass and high-pass filters described earlier. Transistor Q2 functions as a buffer between filter sections to preclude distortion of the response due to loading. Although the biasing values are the same as utilized on the earlier active filters, rebiasing will improve the insertion loss caused by dual series filters in a unity-gain network. Figure 14 displays the response of the network for the values given in Fig. 13. The initial response is reasonably flat for two octaves with good slopes to −15 dB.

Passive RC tee configurations have the poles of the transfer function on the negative real axis of the complex frequency plane, and they occur only once at any given point. However, zero locations are dependent upon the circuit configurations and can occur anywhere in the complex

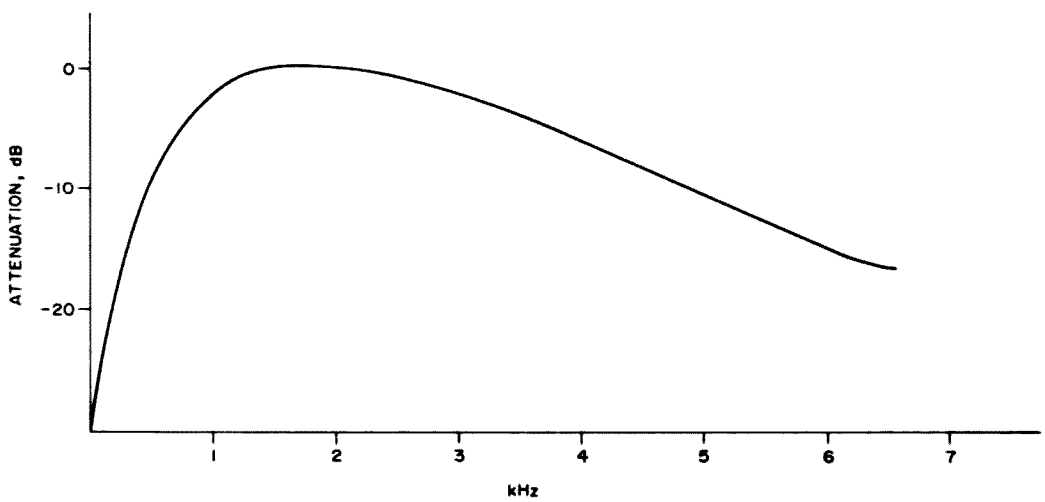

Fig. 14. Active bandpass response.

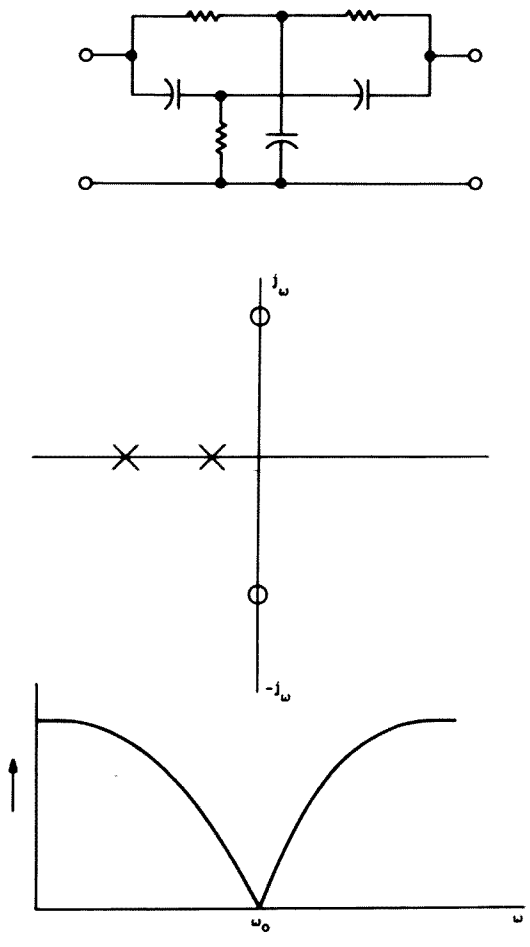

Fig. 15. Twin-tee scheme.

plane. A parallel arrangement of two tee networks and their pole-zero plot and response is shown in Fig. 15. By using the tee network with feedback, the figure of merit, or Q, can be improved by a factor of 80–100 over the value of less than 1 obtained with unity gain.

In Fig. 16, the twin-tee network has been inserted between the emitters of Q1 and Q2. This location precludes the effect of loading input or output which would produce distortion in the response. Rebiasing of the transistors may be necessary to set input signal limits and adjust gain. Operation is similar to the preceding designs in that feedback and gain are varied by R11, R12 and R9, R10, respectively. The values of the components making up the twin-tee network may vary from design to design. To retain a symmetrical response, the network must see a common input and output impedance. The ratios of R4, R5 to R6 and C2, C3 to C4 determine Q, center frequency, and in what area of the transistor curves the amplifier/filter will operate. It is therefore necessary to change the ratios to obtain the desired values of the above listed parameters, in addition to assuring operation of the network as a bandpass, bandstop, or other type of filter.

The following formula may be used to determine center frequency:

$$f_o = \frac{1}{2\pi R C}$$

In designing a bandstop network for 1200 Hz, we might choose a resistance of 1.5 kΩ giving a value of C:

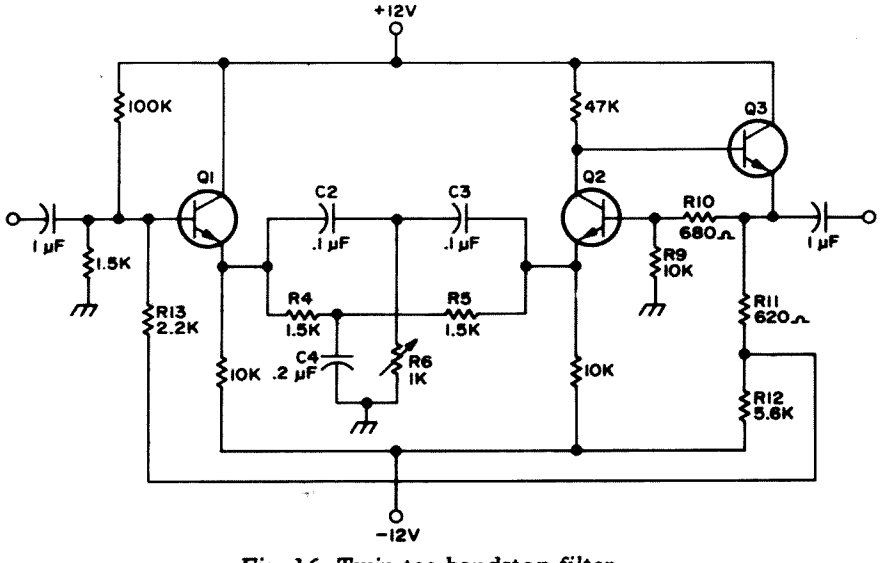

Fig. 16. Twin-tee bandstop filter.

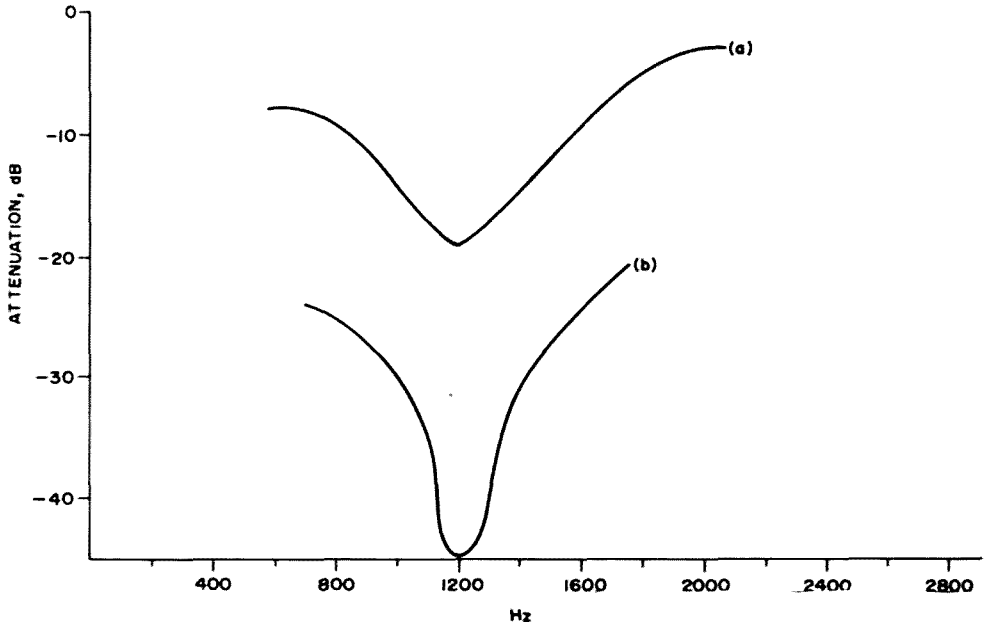

Fig. 17. Active bandstop response.

$$C = \frac{1}{12x10^2(6.28)(1.5x10^3)}$$

$$= 0.088\ \mu F$$

The vertical branches of the twin-tee network normally contain a resistance of half the value of the horizontal component and a capacitance of twice the value of the horizontal component. The tee network of Fig. 16 was breadboarded with C2 and C3 at 0.1 μF for convenience in choosing C4. R6 was made variable to allow final adjustment of the center frequency. The main feedback loop, consisting of R13, was chosen for best performance while monitoring the response on the oscilloscope. A lesser feedback loop also exists from the collector of Q3 to the base of Q1. This feedback is negative in nature and can be used to stabilize the network when required. Figure 17A shows the response for the active bandstop filter.

By changing the ratio of RC in the twin-tee network, a more desirable response can be obtained, as the expense of insertion loss. Figure 17B shows the filter response when the elements of the tee network were changed to the values given in Fig. 18. In addition, the use of less feedback (R13) tended to steepen the low frequency slope. Increased feedback flattened the slope producing the appearance of a high-pass response. Therefore, no feedback was used in the end design. Rebiasing the network would probably decrease the insertion loss.

NOISE BLANKER

Designed for the serious VHF operator requiring effective suppression of interference generated by auto ignition, power lines, appliances, radars, etc. Models available for both VHF transceiver and receiver-converter systems.

Model TNB-250, for Swan 250 transceivers. Features include modern solid state design techniques using dual-gate MOSFET transistors and a special gain controlled amplifier circuit yielding excellent cross-modulation characteristics in strong signal locations. Simplified installation requires twenty minutes without drilling holes **$32.95**
TNB-250C (for Swan 250C) **$32.95**

Model TNB Noise Blanker, designed to operate with VHF converters by connecting in the coax between converter and receiver. Noise suppression characteristics are similar to those of the TNB-250. Choice of 14-18, 100-140, or 125-160 VDC. RCA phono or BNC connectors. Specify for 10 or 20 meter converter output. **$29.95**

Prepaid orders shipped postpaid. For Air Mail add 80¢. COD orders require $3.00 deposit. All products are warranted for one year and offered on a satisfaction guaranteed or return basis. Technical brochure available.

WESTCOM
ENGINEERING COMPANY
BOX 1020 Escondido CA 92025

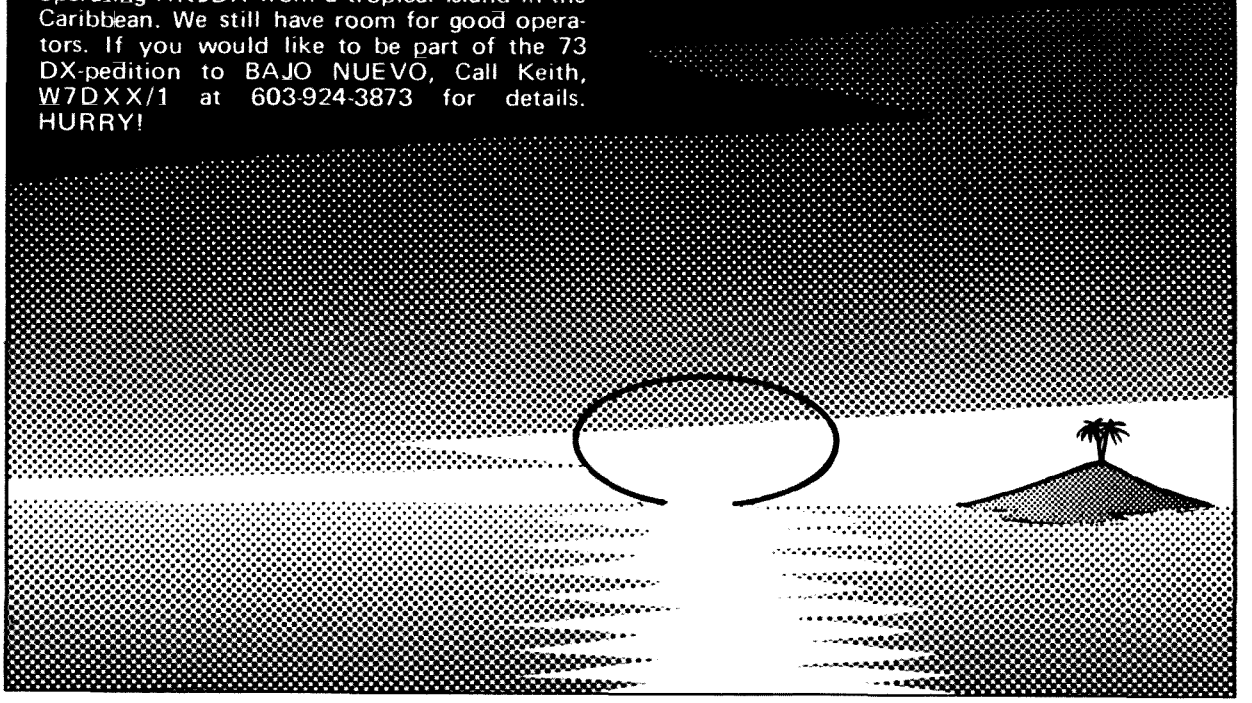
(continued from page 128)

the Knoxville situation will improve. I mention the HXD situation because I think many repeater owners have the same problem – the 80/20 syndrome.

Many of you had the chance to work the KC4DX DXpedition on Navassa Island a couple of weeks ago. How many of you had a chance to take advantage of another first? Wayne Green, W2NSD/1 took along his slow scan gear on the DXpedition and made several SSTV contacts from Navassa with excellent pictures. Wayne will be taking his SSTV gear along with him on his upcoming trip to Jordan and several other rare spots. In fact, he will be operating SSTV/mobile. Should provide a lot of fun and a lot of new countries on SSTV. Although I have not had a lot of time to use it, I am set up for slow scan with the Robot line. I have made a few contacts and find SSTV a lot of fun.

When I proposed DX repeaters a few months ago, I had no idea the response would be so great. Basically, I proposed we have several repeaters around the country interlinked via 10 meters FM. Such a system would allow users of a local 2 meter repeater to gain access to another 2 meter repeater located in another part of the country. Or, the world, for that matter.

Although it may seem complicated at first glance, the system I propose is so uncomplicated it hurts. All that is needed is a 10 meter base station, a tonal decoder, a COR, and a "Fail safe" timer. Here is how the system would work: assume we have a 34/94 machine in California and a 34/94 machine in Florida with the DX link. Under normal conditions both repeaters are simply 34/94; the DX link is inactive. Let's say a Florida user of his local machine wished to communicate with California. He simply transmits two tones. The first tone turns on his local repeater's DX link so that any 29.680 signals heard by his machine will be sent down to him on 94. After he determines the DX frequency is not in use he transmits a second tone that turns on the California 34/94 machine's DX link. He will then hear any activity on the California 34/94 machine. Plus, of course, his own Florida 34/94. After the DX contact has been completed, a reversal of the tones will shut down the DX link.



At this point it would be a good idea to mention the "Failsafe" timer. This is simply a drop-out timer to shut down the DX link after 60 seconds of no carrier on 29.680.

I've shown how two 34/94 machines can be interconnected via ten meters. All that is needed is separate control tones for each repeater and several machines can be tied together in this manner. Obviously, there are a couple of variables, namely conditions on 10 meters. Although 10 meters is generally open all over the country during the day, there are times when the band is closed to a particular part of the country (like at night?) and inter-tie with a certain area may be difficult. But remember, many of the variables of working DX are done away with in this system. Primarily, since we are using crystal controlled frequencies and FM there is no need to tune around a band and no need to call "CQ" for a certain area. If the band is open to the part of the country you wish to make contact with you will have no problems at all. You simply transmit the tone of the repeater in that area you wish to work.

If this system is to work we will have to have some coordination, such as assigning tones and secondary 10 meter frequencies for when activity is heavy. I think the 10 meter DX links for 2 meters can be a great thing for FM. At this time several repeaters are experimenting with 10 meter DX tie ins on 29.680. I envision the day when a 2 meter operator in California can talk to another 2 meter operator in another part of the country. They could both be using small walkie-talkies. Think about this system I propose. Look into all aspects of it. I'd like to have your pro and con reactions to the idea. ... W7DXX/1

ANNOUNCING THE 73 DX-PEDITION TO BAJO NUEVO HKØ

Join Wayne Green, W2NSD/1 and Keith Lamonica, W7DXX/1 as we operate from BAJO NUEVO. Picture yourself next November operating HKØDX from a tropical island in the Caribbean. We still have room for good operators. If you would like to be part of the 73 DX-pedition to BAJO NUEVO, Call Keith, W7DXX/1 at 603-924-3873 for details. HURRY!

LETTERS

Our station here is AB8USA, Command Control Station for MARS Army in Vietnam. We've got about 25 stations over here receiving your mag each month, and it is certainly appreciated by all of them, if you can judge by the comments on the in-country net after the new issue arrives. We also get *CQ* and *QST* both of which are greeted by loud yawns on frequency.

Thanks for the article a month or two back on MARS phone patches. We were beginning to think hams had never heard of MARS for the most part. Actually, although your article implied that most stateside stations are at Army forts, there are also quite a few civilian MARS members on the air with us. For instance, AD7FTN/WA7FTN, A6VVM/W6VVM, A6PXP/W6PXP, it's really unfair to start naming them cause there are so many. The only reason they don't turn in a huge patch count is that they don't have the manpower for24 hour operation. By and large, their operating skill is as good or better than the "pros" at the Army bases.

Anyhow, keep up the fine mag, and don't skimp on the FM articles (like there was any danger of that) since I plan to get up on 2 meter when I get out of the "green machine."

Gary P Novosielski
APO San Francisco CA

We have a few 220 MHz stations going here – WA6BRC, WA6BVC, WA6IRR, WB6OPQ, WB6SUP, WB6ZOQ, WA6HIP and my own, WA6FBY. We are using the CV431A/AR transverter surplus unit, reported in the 1964 June issue of *73* as the ARC 10A.

Perhaps you can borrow a copy from a friend (or put on your scuba gear and go down in the cellar where you keep back issues. I know you store them underwater because I bought a box full).

Anyway, I got on the air for a sum total of $17.50 – how about that! Most of our thanks go to Frank W6VMY over in Saratoga for obtaining these units for us.

Bill Hahn WA6FBY
Stockton CA

On March 26, 1972, and several times since, I worked an SS station giving the call PZ1DX. I sent him a card through the Surinam bureau and received a reply from the bureau today. They state that PZ1DX is not a licensed station and the operator is a "most daring pirate." They request that I pass this information on to all SSTVers so this type of operation can be slowed down.

Jack C. Petree WB4OVX
Roanoke VA

In my opinion CW is about the only unique thing in amateur radio which still remains (since so much amateur gear is commercially made same as the CBers). In other words, if it had not been for CW, I wouldn't have been attracted to ham radio at all. After all, anyone with a good credit rating can buy radios to talk on and can make a lot of long distance telephone calls for even less money, therefore, SSB holds no particular attraction for me. At least it is not why I entered ham radio.

The cartoon on the Feb. cover was really great. I suppose it shows how *73* really feels about CW but to me its just fine. I doubt if there would be any ham radio or *73* if it were not for old guys like him.

Bill Howard WNØEQT
Des Moines IA

Amateur satellites are unique also.

CAN ANYBODY HELP?

I need your help. Twice.

1. Schematic for a link receiver model 7000. I specifically need crystal multiplier factor.

2. Schematic and/or crystal factor for an old GE model 4ER 1A3 type ER-1-A 152-162MC. Both of these pieces of gear will be used on 2 meter FM if I can find out the needed information.

Thank you for whatever help you can give.

Dean BiglerWA7IBT

MICROWAVES

Glad to see microwave feature. Keep it up. Let's get the details on these TRAPATT and IMPATT Modes into *73*. I'm interested in surplus conversions of all kinds AM –,FM, etc. I read KICLL type articles. Interest = .1-10.5 GHz.

Herb Adams
Chula Vista CA

BONUS

I would like to point out that the Larsen Antenna works well as a ¼ wave whip on six meters. I tried it on my mobile at the suggestion of a couple of the locals. The SWR on 52.525 MHz, as measured at the transmitter, is 1.2:1.

A 12 volt antenna relay with auxiliary contacts, salvaged from an old transceiver, switches the antenna and mobile speaker from one rig to the other with the flick of switch on the dash.

Many 2 meter gain antennas will not load at all on six meters. The Larsen Antenna is not only an excellent 2 meter antenna, it is truly a "six and two" mobile antenna.

John Clough W9LPO
Madison WI

Get six for the price of two.

HAMS AS INNOVATORS

As a professional who has made his living since 1928 in marine radio and crystal servicing with ham radio to relieve boredom, a few reflections to spur amateur technology may be in order.

To this observer, the current revolution in marine and commercial radio towards VHF and maximum utilization of air space thru SSB represents a constant and growing pressure from commercial interests. This force can in time seriously threaten amateur frequencies.

It behooves inspired, adventurous hams to explore the unseen borders of technology for a new transmission medium to replace SSB. Twenty years ago a technician friend had detailed a method using vacuum tubes for voice transmission using a carrier and no sidebands. In the spectrum now occupied by one sideband it would be possible to accomodate five such carriers.

The system was too ponderous using tubes but with solid state and proliferating IC's it seems the instinctive way to do it. Lacking a proper name, it's been called True Amplitude Modulation or Carrier Power Modulation. Looking at a scope you see a carrier moving up and down transmitting intelligence, with no sidebands.

The Tiny Tim tonality of SSB begs for an innovative system to restore individuality to voice channels. Here is a tip: RF is being multiplied and divided, up and down. Why not the voice frequencies! Portions of sideband speech before entering the voice coil could, in segments, be multiplied up and divided down and reinstated into the voice channel to obtain a synthesized (and restored) quality of speech not unlike pre-SSB voices on AM.

Want to bet these projects will be solved by hams before they're uncovered in research laboratories?

F.W. Anderson W7AR
Seattle WA

Usually you are right on top pretty much on amateur affairs, but maybe not quite in regard to 160 meters. Re: "The Son of 160 M."

MORE LETTERS

The 160 band is very much alive with high power outlawed so no high power boys to contend with.

I have been back on, mostly early mornings lately, for about 8 years. I operated 160 some before WW 2. For a while I was the only really active Florida station, but that has changed in the last few years. I don't chase DX myself, but some do, with some up to around 100 countries. There is much CW and, quite a bit of the AM modes, DSB full carrier and SSB SC, also a few DSB SC. The popular SSB rig is the Drake R-4, T4X combination. (SSB is AM Right?)

I did feel as you that the manufacturers should put 160 on the rigs but maybe that would make our only medium frequency band have as much qrm as the HF bands.

The only statement that I 100% disagree with is your last sentence. 160 is *already* a "Hellova band" and *is* and *has been going*.

On another matter regarding an answer to a letter from a reader. You stated that FM wasn't available on a ham communications receiver. (This may hurt, but not too much I hope.) Read Henry Radio's advertisement for the Kenwood R-599 receiver. Not only does it have 160 but FM and 2 meter FM with the optional installed inside converter. See back cover of March 72 issue. Also in some earlier *73* magazines. (I own one.)

Harold J. Tucker K4HXW
Melbourne Beach, F L

PROJECTS

Re the "Crystal Checker," 73 November 1971 issue, page 55, I recently completed this construction project and it has worked out very well. Due to supply difficulties I had to substitute RCA SK3019 for 2N3607 transistors and 1N270 diodes for 1N914, but everything worked out okay. I also substituted a vise-like arrangement (with one metallic split jaw and one insulated jaw to replace several xtal sockets since I could not seem to get a variety of sockets). Please give us more useful construction projects like this one. (cc to author Mike Kaufman K6VCI)

Vernon Jones
Kennebunk Maine

I have been on the air since January of this year. During this time I have received your magazine and another which will remain QueSTionable. I prefer *73* over the other many times for a number of reasons, but mostly because you have some really good articles and don't waste your time with 40 pages of calls who entered contests. I also like your circuit section, but how about some more real QRP transmitters (like in microwatts).

Joseph Katz WN1PHJ
Glastonbury CT

I don't think I can bear to do without another issue of *73* Magazine. I think that the $11 for two years (check enclosed) is well worth it. The humor alone is worth that much. Anyway I heard that 1973 was going to be a big year for the magazine. Please start my subscription as soon as possible.

Jefferson W. Barstow
Hancock MI

Due to the move to UK of the Manager the BE/NL/CND/UK Forces QSL Bureau will close from 6 March 1972.

All operators and Bureaus are requested to forward all cards in the future to the *German Amateur Radio Society, Box 88 MUNICH, GERMANY*.

Thanking you for your assitance.

J.T. Worrall DL2AH/G3XBA

In regard to letter on page 6 of May issue of

In regard to letter on page 6 of May issue of *73*, I wholeheartedly agree with Ron WA1PMS and his recommendation that 146.52 be used as a simplex channel and hope others will join together in urging that this be done. It seems when anyone builds a new repeater (down in this part of the country) he wants to, and does, put it on 146.34/.94 or some other transmitting frequency with .94 as receiving.

Charlie Brown WB4OOT
Cataula GA

Thought you might be interested in comments from a Mexican ham regarding reciprocal license agreements. In a conversation in Mexico City he expressed the thought that Mexico and Mexican hams have nothing to gain and much to lose if they were to grant licenses to U.S. visitors. The loss – being mowed under by U.S. operators and with so few Mexican visitors requesting operating privileges in the U.S. it seemed rather pointless. I could think of no good argument. You have to hear it to believe how quiet the Hertz are in Mexico.

L. P. Scott WB6IKM
San Marco CA

Try working an FM repeater in NYC

Getting started on 2m FM meant that I had to buy a lot of crystals. As these are very expensive here in Sweden, I ordered them from Jan Crystals, Florida.

Unfortunately I made a big mistake! I forgot to specify the parallel capacitance. Shame on me! Of course I ended up on the wrong frequency.

As I was dying to get started I returned the crystals asking them to correct these and to return to me by Air Mail. Three weeks later I had the crystals back with correct frequencies and no extra cost.

Take my advice, ALWAYS specify the parallel capacitance. If you do not know how to figure it out, enclose the circuit diagram with your order or state the type of transceiver you are using.

Thanks JAN CRYSTALS for being so cooperative!

Eskil Persson SM5CJP
SWEDEN

After reading the article in the Oct. 1971 issue, "Back to Mother Nature the Easy Way," I was delighted.

Soon, three lengths of copper pipe were in readiness for installation. The water hose was attached, along with a valve to control the water. A step-ladder was moved into place, the equipment readied, the water pressure applied.

The first results were amazing. Since the water pressure on our tap was about 90 lbs. per sq. in., an immediate fountain of mixed mud, water, plus some grass roots, ascended to a height of the operator plus about three feet. The pipe had gone down about 8 in.

Moving the lower end of the pipe to a new position, or positions, resulted in a maximum depth of about 10 inches to be reached.

The operator, wearing a garland of water, mud, and a few strands of the grass, reconsidered. By no means could the method used by WA1FHB be used in Boulder, Colo., not where we live anyway.

The clay, rocks, and boulders, underlying the thin layer of grass, is more than anything less than a diamond bit, bulldozer, or dynamite, can move.

I have been using a crowbar, post hole digger, cuss words, blisters, and whatever help can be mustered, trying to dig two holes, just three feet deep, into which I intend to put bronze screening, along with sulfate of copper crystals, to get some sort of a ground. I have a tower that needs grounding to discourage lightning from paying us a visit – indoors.

A solution to the problem has been found. Go mobile!

Ray R. Rumfelt WØMYY
Boulder CO

I make reference to your 73 circuits page in the April '72 issue wherein a crystal calibrator is described. The 1K resistors R2, R4, and R5 are not sufficient to protect the inputs of the 7400 gates from excessive voltage. This IC has an absolute maximum input voltage rating of 5.5V, which is easily exceeded due to noise or poor regulation of Vcc. This is especially likely in amateur equipment. Instead, the output of the fourth gate (pin 3) in the IC should be used as the input to pins 4, 10, and 11. The inputs to the fourth gate (pins 1 and 2) should both be grounded.

E. Douglas Jensen
St. Paul MN

STILL MORE...

I have frequently run across U.S. nationals enjoying the privileges of ham radio in foreign countries, yet it is not possible for an alien resident to find similar privileges here. It is true that a foreign licensed "ham" whose stay is non-permanent, can obtain a portable license, and while this is a step in the right direction it does nothing for the rest of us "furriners."

The whole world is now undergoing a revolutionary upheaval in thought. The old shibboleths and customs are under examination. Beliefs, customs and even fears that guided our social behavior in the past are being examined with honesty for a change and we have been startled to find how empty some of them are. None can deny that if an injustice exists, at the very least this society has tried to do something about it.

Well, here is another opportunity, for it is my conviction that an injustice is involved and the strange part about it is that neither harm nor benefit for anyone serves to perpetuate the injustice. It is probable that this prejudice towards foreigners exists merely because it had merit at one time and like the laws on spittoons, no one has taken the trouble to update the rules.

In this day and age it is a little difficult to imagine ham radio as a "cloak and dagger" arena, and, even if it were, I doubt that an alien resident would be more so inclined than anyone else.

Perhaps not many people realize that an FCC license is required to operate a car or truck telephone; a model airplane, car or boat; citizens band walkie-talkie; etc. I often wonder whether the poor "furriner" is entitled to operate his garage door opener.

Understanding is a thing we all cherish and, in this case, it seems like such a simple thing. All we ask is permission to apply for a license. This will harm no one but will benefit a few.

J.B. Dellis
Menlo Park CA

I would like to compliment you on your super FB General Study Guide. Thanks to it I will be sporting a WB2 call in a few weeks. I plan to get your Advanced class one in a week or two. According to the FCC official who administered the test to me I did very good on the exam. He refused to disclose the exact mark but still I am very happy to have passed. This is my second try at the exam. The first time I used the ARRL license Manual and Understanding Amateur Radio to study.

Congrats for a job well done. See you on 14 MHz as WB2KFG or as WB2DCS (it better be, I ordered QSL cards for WB2DCS). I have been told that you have a very unique QSL. Is it true? Any chance of a sample of *73* and/or your QSL?

Harry Linzer ex-WN2DCS
Malverne NY

I am writing in regards to the article on MARS in the May issue of your magazine, by Mr. Harry C. Simpson, W4SCF/A4SCF.

The article was well written and to my knowledge, this is the first time the Military Affiliate Radio System (MARS) has received such recognition in a National Amateur Radio Magazine.

Being connected with the Third US Army MARS program as the Command MARS Director, I certainly appreciate the fine publicity and would like to see more articles of this nature.

Harold E. Mulkey
MARS Director
Fort McPherson GA

How could you have committed such a dastardly act? The article appearing on page 37 of the May 1972 issue entitled, "How To Get The Stuff Into The House," written by Bill Lowenberg W2OOJ has probably done more to set back the program of amateur radio than any other single act since radio propagation was first discovered. No doubt the intention of W2OOJ was to assist those in the fraternity in the general up-dating and improvement of their stations. However, the simple act of putting into print the various specific methods used by we hams in the acquisition of equipment has placed a high percentage of us in a most disastrous position. Many of us have been using one or more of the various schemes outlined by Bill in his article for years with an extremely high degree of success. The terrible part of this whole thing is that the methods which have been exposed are some of the best in the average married amateur's repertoire not just some second rate ploys.

Normally, *73* arrives right along with the Woman's Home Companion, the Ladies Home Journal, Better Homes and Gardens and such other female trivia and is just thrown on the desk by my XYL. This month, it arrived without escort with the exception of a couple of my wife's credit card bills. That one chance in a million happened! Being not particularly interested in the bills, the XYL casually thumbed through the *73* while waiting for me to come home for lunch and found the article It couldn't have happened at a more improper time. I was in the process of using scheme number two (page 38) to acquire a brand new SSB mobile rig with AC and DC using my old DX-40 and some junk box material on an "even trade." She was on to me in a second and ruined five weeks of careful preparation and offhand conversation, (which, incidentally, requires a better than average memory).

She now reads all of the ham ads and knows exactly what each piece of my equipment is worth on the used market, has made inquiry at the local parts house regarding my dealings and has directed the proprietor to mail any invoices for those "little minor maintenance items" necessary to the proper operation of my station directly to the house instead of to my office. She now realizes that a two meter slot beam is not necessary for the reception of Cable TV. A complete inventory of my spare parts has been effected and I have been directed to dispose of any surplus not vital to the operation of the station with any proceeds therefrom to be credited to the household operating account. Even worse, she is now using my code tapes and records and wants to keep the DX-40 for her novice rig. I have just forked over enough cash to cover a new spring outfit, complete with matching purse and shoes and we are having two perfectly good chairs recovered.

I have been through more thorough, detailed and humiliating interrogations in the past week regarding my actions over the past 19 years and 8 months than could have been devised by the most fiendish minds of the Gestapo when at their zenith. It's worse than the disclosure of the Pentagon Papers. In the future, this black mark on the record of amateur radio should be referred to as the Lowenberg Affair.

How a fine amateur and master trout fisherman like Bill Lowenberg could so conspire with *73*, to perpetuate such a dastardly act, is beyond my comprehension. I cannot cancel my subscription because I am paid in advance for two more years and the XYL thinks your publication a most excellent magazine. A pox on you all.

Garry Owen W5MDG
Roswell NM

Would you kindly remind your readers that the frequencies: 53.10, 53.20, 53.30, 53.40 , and 53.50 MHz have been recognized by the FCC to be *Radio Control Frequencies* for those licensed radio amateurs who engage in remote control of model boats or airplanes.

It seems that interference on these frequencies is on the increase and has, often, caused loss of control, something which can be quite a catastrophe especially in the case of model airplanes which have been caused to crash.

Besides the countless hours spent in building these models the cost involved ($300- $500) in these model planes make interference a very serious problem.

Considering all the frequencies available to hams who operate for communication purposes (CW, phone, RTTY, etc.) it seems reasonable to ask them to stay clear of the above mentioned frequencies.

Furthermore, since it is impossible to build fancy receivers in the very

...AND MORE!

small space available, it would be appreciated if a reasonable guard band (say 6 kHz) could be respected.

Pierre J. Catala
Needham MA

Del Wininger (January issue) is right when he says it is not likely any move to revise the symbols of the Morse code would succeed (though his reasoning is debatable–surely the real reason is that it would be expensive and inconvenient to change such a deeply entrenched language).

But the idea of everyone sending Morse as if it consists of letters rather than words is a bad one, except at the very beginning of the learning process–learning the alphabet. Once the letters have been grasped it is surely important that words should be read as words. This is the whole difference between an expert reader and a poor reader of *any* language. Once you have learned how to read, it is easier to read "been" than it is to read "b e e n" (which is the written equivalent of letters at 20 wpm and spaces equivalent to 7 wpm). Sent in Morse code at any speed above about 5 or 6 wpm, "been" has a beautiful rhythmic sound as an integrated group, and Del's method would destroy the sound of the *word* and substitute for it a jerky succession of isolated letters with little relevance to each other.

When you are reading this text, do you "search your memory after each letter appears" in each and every word? Of course you don't, or you would never get through an issue of *73* before the next one arrived.

Unfortunately too many bugs or keyers are already set to a dot speed faster than the dashes are sent, although fully auto electronic keys have made a vast improvement in the overall picture in recent years. There are not so many W6 calls sent as . – – – . . . . . etc. these days, because the sender cannot cope with the dashes if he has the dots set too fast, so he slows the dots down to a speed he can handle.

The ratio of dots to dashes and spaces is fine in the code just the way we have it–all we have to do is send it properly, and if Ted McElroy could read standard code at 75 or 80 wpm there is no reason why lesser mortals can't manage 20 and 25.

There is a technical reason why Del's idea is unwise too. There are many filters in use for CW which ring enough to obscure the dots when sent at 45 wpm (which we would have to do to get a message through at a basic 12 wpm or so).

Candler had the right idea in setting down groups of words of progressively greater length for the pupil to "get the tune of." Rather than vary the ratio of character to space, Candler preserved the ratio and upped the speed. You will agree that if you can read a C at 25 and a Q at 25, you can read CQ as a group at 25, also simple groups like ES and RST and DE, then CONDX etc.

I would compromise with Del and propose that maybe we should leave a longer space at the end of each *word* but I am afraid that would bring an irate letter from someone saying "that would make it hard to read sentences as an entity."

What we should do in the ham fraternity is keep the code the way it is, but USE IT PROPERLY.

For example, if we think the other guy isn't hearing us too well, or that we might be missing some dots ourselves, *slow down* instead of repeating several times. Only this evening I heard a station sending "RST 569" four times, three of them wrongly and the last one on the dash paddle as a side swiper manual key. That is ridiculous. I am sure that if he had slowed the bug down to 15 wpm he could have sent it perfectly just once, and it would be enough.

Then how about finding something shorter than CQ for a general call? Like AA (.–.–) for example, or if traffic people find that confusing, some other unused short coupling.

And how about dropping the T9 on the CW report? On the few occasions it isn't T9 we could explain what it *is* like. What we should have instead of the tone report is a click report maybe!

Let's not revise the code. Let's just use it more sensibly.

Bob Eldridge VE7BS
Burnaby B.C.

I am very much pleased with the QRP articles of the February issue. I have been using a home brew solid state QRP transmitter for quite some time with very good results on CW. The TX consists of a vackar FET VFO with a two transistor isolation stage, one amplifier stage, all on 7 MHz followed by a two diodes doubler to 14 MHz which drives the final transistor; output is 800 mW, antenna is my regular triband TH6DXX on 30 ft height. I also tried 50 mW, 100 mW, 200 mW and 500 mW, all with fair to good results on 15 and 20 meters. However, my 800 mW always works well for me on 20m. I have worked numerous W's and also European stations. It s great fun to work QRP. In this country it is very hard to find any parts for transmitter use, so my TX is built with all sorts of odds and ends.

Otto W. Morroy PZ1AC
Paramaribo, Surinam

I always enjoy your publication. Your approach is refreshing and even old staunch ARRL men like myself appreciate it.

I'm a free lance writer/photographer. I came across the paragraph in the Feb. 72 issue regarding a small "independent territory between Norway and Sweden called Morokulien . . . an international refugee area . . ."

This is a put-on, Wayne. I was hoping I'd run into something and I could do a piece on this "small independent territory." The Royal Swedish Embassy advises: "There was never any real place called Morojulien in Scandinavia, only an imaginary spot somewhere in between where the two brother nations could meet and have fun – in Norwegian, "moro," in Swedish, "kul." This mysterious location existed only in a popular TV program enjoyed by Swedes and Norwegians some ten years ago . . . "

I suspect old Eric 5N2ABG, is trying to drum up a little publicity. Actually, there is no such place as Scandinavia. I note that the post office box combines both Norwegian and Swedish and I'll bet you a nickle to a herring that our OM Eric is associated with public relations someplace. Maybe they're trying to get some Lend-Lease or something.

INDEX 1971

It was our intention to print a cumulative index of the past twelve years of 73 Magazine and this is why no 1971 index had appeared in print. We have received many letters requesting an index and have decided to print the 1971 portion of the index. The twelve-year list will be published separately as soon as it is complete.

ANTENNA

Parabolic beam for 10,15,20m—WA2SJZ 66 Jan
Inverted attic antenna—W2SF 81 Jan
Tuning all-band vert. antennas—W5QKO 85 Feb
Trap-type vertical antenna—W2EEY 18 Mar

W7DXX/1

The W7DXX/1 Column is dedicated to those of you who read 73 from the back to the front. It also gives me the chance at the last word on a particular issue.

I am trying to average an hour or two per evening on 20 SSB since I have to start my DXing anew from the new QTH in Peterborough, New Hampshire. I'm running the limit to a 3 element 20 meter beam up 75 feet and the QTH is 800 feet above average terrain. A beautiful location. It's much easier to work DX from this location than from Washington State. In fact, after just a couple of days I am halfway to the 100 countries mark.

I had a very nice 45 minute chat with Ole, OY9LV, the other night on 20 SSB. He runs low power to a dipole. However, with his mountain-top QTH on Faeros Is., he puts out a very nice signal. Ole is sending me some pictures of his shack and QTH. I'll be sure to include them in a future column. I had a small chance to appreciate what many DX stations have to go through with the stateside QRM. During our 45 minute QSO dozens of stateside stations kept breaking each time we would turn it back to each other. And then, when we finally did sign, he was mobbed by hundreds. God! I couldn't live like that. By the way, W3HNK is the QSL mananger for OY9LV.

On the subject of DX, Wayne Green and I will be operating from Bajo Nuevo (HKØ) for the November 11th week end. We have room for several more good operators. If you'd like to join us on a DXpedition to a rare tropical island, get in touch with me ASAP.

I put the *73* Magazine repeater back on the air a short time ago (WA1KGO 19-79). We have a couple of solid-state two meter repeaters on the way so we should have a couple in operation from our mountain – Pack Monadnock, Peterborough. One of them, the 19-79, will have a DX tie-in to 29.680.

You would not believe the two meter activity around the northeast. Virtually, every two meter FM frequency is occupied by at least one or two repeaters. Wayne and I took a trip to our repeater site the other evening in his mobile. He runs a 20 channel transceiver with a 100 watt amplifier. Needless to say, we had a blast. The only problem was that it would take quite a while for all the repeater tails to die out each time we transmitted.

I keep a 20 meter sked with WA4JGF, WA4QXC, W4EAL, W4LQC, and several others every Saturday morning. These fellows maintain my Knoxville Repeater (W4TEA 16-76). They tell me that they are progressing well with several new projects such as several autopatch lines to different exchanges, and the DX inter-tie to 29.680. Knoxville already has a very fine repeater (K4HXD 34-94). The repeater was put up by and is maintained by George, K4HXD (known to several of his "Group" as HIS EMINENCE). HXD is suffering the same problem most repeater owners experience. I call it the 80/20 syndrome. Namely, each repeater has 80% talkers and 20% doers. It is a sad fact but most repeater users highly praise the machine they are using until help is needed. As soon as the chips are down, or the repeater for that matter, very few people are available to help. Also, George must learn to passively monitor his repeater and not take every opportunity to "hop" on frequency and criticize repeater users. Also, he must learn to do his own thinking and not let a few do the thinking for him. I am sure when HIS EMINENCE realizes that he is in the same boat as most repeater owners,

CONTENTS

4 **Navassa** **W2NSD/1**
The intimate inside story of KC4DX!
16 **Slow Scan Television** **W9NTP**
Introduction and general principles.
28 **Premodulation Speech Processor** **W6AJZ**
Get a 1 to 2 S-unit increase in signal.
33 **Two Buck Signal Generator** **WB4MYL**
For 2m FM and stuff like that.
35 **Transmitters, Then and Now** **W2FEZ**
History.
41 **Practical Amateur FM Repeaters** **K9STH**
Next month impractical FM repeaters maybe?
58 **El Cheapo Test Probes** **WB4MYL**
Cheapskate use for old marking pens.
60 **Prog Line Power Supply** **K6VBT**
Actually this will power any surplus FM rig, getting you on FM for beans.
62 **Random Access Switching** **W9SEK**
Some push-button control circuit ideas
65 **Diode Receiver for 432 MHz** **K1CLL**
Also receives radio signals – like FM.
73 **The Taming of the HHRW** **K7TCU**
Why have the wife hate amateur radio when she can be induced to grudgingly coexist with it?
75 **S5 Preamp Compressor** **VE3GSP**
It really does make a difference.
77 **Push-To Talk For The Sixer** **WB2YWO**
Plus other modifications for this and the Twoer.
81 **Audio Distribution Panel** **K3PUR**
And phone patch, plus other goodies.
87 **Voltage Multipler Supply for Scopes** **K2BEH**
A 300-volt transformer can generate 1500 volts thisaway.
89 **VFO Operation for the Twoer** **WB6FVW**
Using the Heath HG-10. Should work with the Sixer too.
91 **/MM Maneuvers** **VK4SS**
Wherein our hero fixes a marine rig, answers a QRR and gets into deep trouble.
97 **The Sun and Radio** **W4ZBE**
Science feature.
105 **Poor Man's Transcanner** **WB9FOP**
Mating a scanning receiver to an FM transceiver, the Regency HR2 and TMR-8 in this case. Result: an inexpensive transcanner.
107 **SCR Regulator for KW Power Supplies** **W3HXO**
More flexible than one of those old great big expensive Variacs and voltage regulates to boot! Your HV supply will be obsolete without this.
115 **The Ideal Crystal Oscillator** **K1CLL**
For that 1296 MHz rig you are going to build.
117 **The HW-16 on Phone?** **WN2REW**
Simple modification.
119 **FM Adapter** **W1LE**
FM gadget for low band receiver so it will work with those VHF converters and let you listen to all the repeaters.
127 **Electric Timer** **W6LM**
Turns things (like rigs) on, off, or whatever you want.
129 **Circuits–Circuits–Circuits** **WA1KGO**
Enough data for experienced builders to make do and references for beginners to get more info.
139 **GDO Coil Extension** ..... **WAØABI**
For short GDO's.
141 **50 MHz DXing** **WA6CPP**
The band is open a lot more than you suspect. Here's how to get more DX out of it.
158 **Home and Auto Burglar Alarms** **K6ZFV**
Are you waiting to get ripped off before you put in an alarm?

73 Magazine is published monthly by 73, Inc., Peterborough, New Hampshire 03458. Subscription rates are $6 for one year in North America and U.S. Zip Code areas overseas. $7 per year elsewhere. Two years $11 in U.S. and $12 overseas. Three years $15, and $16 overseas. Second class postage paid at Peterborough NH and at additional mailing offices. Printed at Menasha, Wisconsin 54952 U.S.A.* *Entire contents copyright 1972 by 73 Inc., Peterborough NH 03458.* *Phone: 603-924-3873.* *It's too darned late to sign up for the 73 tour in September and include Moscow, what with the incredibly slow system they have going, but it is possible to go along and hit all other stops if you send in your $200 deposit immediately. Send for poop sheets on the tour from Lin Green, 73, Peterborough NH 03458. Don't miss the trip of a lifetime. While it looks as if the Bajo Nuevo trip is filled, there may be room for some standbys . . . see page 112 last month. Positions are open in the advertising and editorial departments for experienced amateurs, OM or YL . . . they don't pay a lot but they are fun . . . and what is more important? 73 is growing rapidly. Now stop reading this trivia and get to the articles . . . and most important, send in that readers service list. The agonies of deep personal torment will plague you if you don't send it in.*

EDITORIAL BY WAYNE GREEN

Caveat Emptor

That means buyer beware. Rather than go through long lists of problems that fellows have had with various firms, getting into a hassle over nits, perhaps a short list of who to contact for details about what firm is in order.

If you would like consumer info re: HT Specialists, also possibly known as Curtis Communications, in Willowdale, Ontario, write to Bob Coburn W1JJO, RFD 2 Tinkham Lane, Londonderry, NH 03053.

Consumer info on Herbert Gordon Company, also known as Bolton Labs, and possibly other names, Harvard, Mass., check with Charles Terry W4FZX 1300 Shady Lane, Orlando FL 32804; James Sandberg K6HE, 1138 E. Rustic Road, Escondido CA 92025; William Watts WA0SQL, 1020 Main, Durango CO 81301; Stanley Allan, R1 Box 99, Durango CO 81301; James Thurber W4ICF Box 373, Boynton Beach FL; Thea Vance, 212 Ellendale, Crown Point IN 46307; Max Fraser VE4MF, Binscarth, Manitoba; Carl Pohlner K3PZE, 1780 Joan, Balto MD 21234; Harvey Wills K6KYC, Box 462, Independence CA 93526.

There is quite a bunch of ham gear made up in Japan that is simply awful. This should not be confused with the fine gear that is being imported by reputable companies such as Standard, Drake, etc., which meet all U.S. specifications. Some of the rigs couldn't meet specs without a major rebuilding job. For instance the Standard 145, available only from Japan, and equal only in looks to the U.S. imported Standard 146, failed miserably in the *73* labs and seems like a real loser. Please watch out for anyone importing or even selling these – and watch out for anything else they are selling for if they will try and foist a 145 on you they may have no scruples about selling other useless gear.

FCC At It Again

Several of the operators using the WA6ZDI repeater in Los Angeles have received citations for signing their calls as "mobile" instead of "mobile six." Yes, this really happened. It seems so outrageous that it must be a put on, but I've seen the citations myself and an FCC engineer did really spend his time and our money enforcing this obscure and insignificant flyspeck in the amateur regulations.

Step two of the citation process has been more jolting to those using the ZDI repeater. This machine has an input of 146.61 (honestly!) and output on 147.33 (yep!) with the result that the Tech users, though they are personally transmitting within the Tech band, are being repeated out of band. This brought on more citations from our friendly citation center. The Techs involved answered the citation by pointing out that they were at all times keeping their transmissions within the Tech band. Clearly the persons cited were not in violation of 97.7(c) – yet they have received no further communications from the FCC. The result of this is that those cited are afraid to transmit on 146.61 unless they hear further. Many of those not yet cited are afraid to transmit on 146.61. It is only fair that these chaps get an answer.

When you consider how hard the crew in Washington are working to provide leadership and guidance for amateur radio, it is a shame that problems such as this are souring things at the field engineering level.

The Case for 34–94 Repeaters

Probably one of the most hysterically emotional things that I could write about would be a call for more repeaters on 34–94. I know of no way to get more FMers up tight and furious. I shall write about it.

There is no question in my mind that there is probably more unanimity of mind among FMers on the subject of there not being any more 34–94 repeaters than just about any other aspect of the field. Not only do they not want more, they passionately want the repeaters presently on 34–94 to get the hell off – and now! I'm for more 34–94 repeaters.

Before you put my swimming against the stream down to my well known perversity, would you be at all interested in some of the factors which went into my decision? Well, if you don't even *want* to know what factors are that are involved, then you do indeed have a closed mind. Okay, now you at least will give an eye to what I have to say, even though your mind may be made up, no matter what it is – right?

Consider, if you will, that there are more 34–94 repeaters around the country than any other pair. Note that I asked you to consider this, not draw conclusions from it. Consider also that virtually every transceiver on the market today comes with a 34–94 pair of crystals. There is *no* other channel pair that is generally provided with new transceivers. Does it make sense to have at least one 34–94 repeater in each area of the country?

The fly in the ointment is, of course, the inclusion of a 94 transmit crystal in most of the transceivers, making it so the 94 channel is often used for simplex operation. And, in most cases, where there is a 94 repeater, simplex gets wiped out when the repeater comes on. QRM = anger.

Okay, next step. Obviously both simplex and repeater operation on the same channel are incompatible. Which should give? Should we try to move all of those 34–94 repeaters to other channels, thus giving the buyers of transceivers no repeater to use when they first get their set? It isn't all that difficult for them to get a pair of crystals for the local repeater, so perhaps that is not an important factor. But is it any more difficult for them to get a pair of simplex crystals such as 52?

No other repeater pair comes near being as popular as 34–94. This means that the amateur who travels a bit must have several sets of crystals with him if he is going to use repeaters in the towns he visits. Be honest for a moment please – can you really say that there are *any* amateurs who do not travel? Just about all of us find ourselves in another area of the country at one time or another – and just about all of us want to be able to use a repeater when we get there.

Let's say you live in New York and you have the 13–73 channel set up for using WA2SUR. You go to Boston and you are out of business. Even if you are set up for the other New York channels such as popular WA2KEC on 40–995, you are still cold in Boston – and in Philly – and in Washington – and Chicago and so forth.

Would it really be all that painful to have a 34–94 repeater set up in each major city so visitors would have one common channel to use to get acquainted? Would it really be a big bad deal if travelling amateurs with a TR-22 and its 34–94 channel could know that they would have a channel to use wherever they were? Would it be that bad if HT-220 owners, most of whom have one and one only receive channel, could work a 34–94 repeat-

(continued on page 70)

The KC4DXpedition

Wayne Green W2NSD/1

One of the fellows on the DXpedition to Navassa was musing over what it was that made Navassa so interesting a place for a trip. Why not go to Antiqua or some other place? Navassa has the advantage over most of the other spots in the Caribbean – it is seldom hammed – it is awfully hard to get to – no one lives there – the seas are often against you – the weather is hot and the cliffs are awe inspiring. It is a lot different from going ashore on an island with a dock, moving into a nice hotel room with ice water and a restaurant, and setting up a DXpedition.

The intrepid ten, gathered around for a round of beers before going aboard for twelve hours of nausea, sickness and distress.

Ten of us met in Jamaica for the 1972 Navassa Island DXpedition. Eight of the group were from the Atlanta area, one from Philadelphia and Wayne from New Hampshire. Chaz Cone W4GKF made most of the arrangements for the trip, in between his work for IBM. The Philly man was Rick Feld K3FPY, the only dedicated CW man on the trip. Rick runs those 800 watt sound systems used by the top rock groups and swears that his hearing has not been permanently damaged.

Our captain of the Tycoon, Busha, said he had been by Navassa the day before and that the seas were very high at the time and that unless they had subsided we would not possibly be able to land. Great news. All of us managed to get aboard the 41' boat along with about fifty boxes of equipment and supplies and we putted out of Kingston harbor just before midnight. Chaz turned white moments later and assumed his permanent leader position with his head over the rail, a spot which he kept for the next twelve hours. Judging from the convulsions he ran quickly through dinner, lunch, breakfast, and midnight snack the night before before we reached the open sea. He then worked his way back through several days and was about two months back, doing everything possible to dredge up more by the time Navassa hove into view.

Chaz was not by any means alone. The seas were mighty and our little boat went up and down like a roller coaster, smashing suddenly to right o left, nosing into a giant swell, spra shooting into the air. It was a ver rough trip and the only winners wer the school of fish trailing our boat t pick up the free lunches being le behind.

Chaz Cone W4GKF of Atlanta and IBM who organized the effort and got the license, the Coast Guard permission, etc.

The gear filled all of the bunks i the cabin, leaving only a few chai

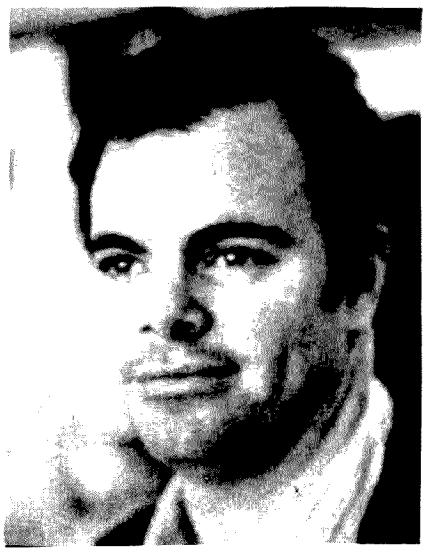
ceiver and making contacts. He'd lo ed up one of the fishing outriggers 75m and the mismatch was so b that he had to run about 0.5 watts keep from blowing the final tubes. I did manage to work 6Y5CB up to couple of miles DX. For some obsc reason he had not thought to bring antenna tuner.

Skip Staub K4TMA

Three of us headed for the flying bridge. It was flying around a lot too. We huddled on the seat around the helm and held on for dear life. There was just room to lie down scrunched up, but no way to stay put without grabbing for something every minute or so when the boat would take a particularly steep dive or list. We all spent the night too tired to sit up and too battered to sleep. You might call it aggravated rest. It got us in shape for the strenuous ordeal of moving the ton of gear ashore the next day.

As day broke Busha passed around some saltines for breakfast. Saltines re supposed to be the best thing for a seasick stomach. They were great – soon there were showers of saltine flakes billowing back from the boat looking for all the world like snow as



eve Smith WA4VWV, another Atlanta pilot and a rned good ham operator.

even that Spartan breakfast was rejected. The heartier stomachs settled for crackers and cheese. Even the best of constitutions were not any too stable after that shaking up.

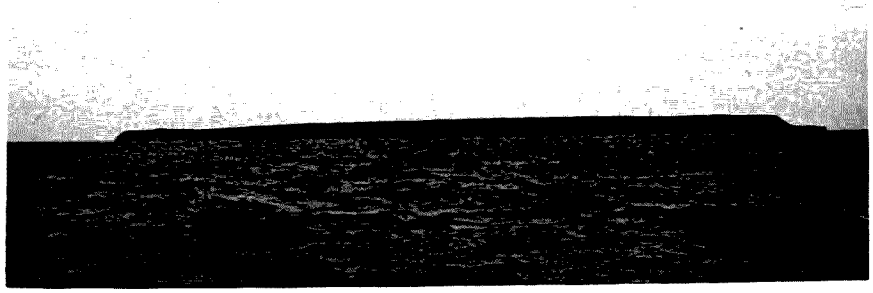
Busha, asked every one or two minutes by the whiter members of our group, kept answering that we should see Navassa along about 9:20 AM. It is a credit to his helmsmanship and navigation that Navassa appeared dead ahead on the horizon at about 9:17. The Tycoon was making about 10 knots. It could do about double that in calm seas, but any more speed would have pounded the boat too hard.

Navassa got larger, looking like an upside down pie plate floating on the water. The plateau is about 400 feet out of the water. It is ringed by a narrow flat area which is about 75 feet up from the ocean. There are no beaches. The entire island is rocky cliffs and quite impossible to climb. The only spot where the island can be reached is a tiny indentation on the south coast called Lulu Bay where the U.S. Coast Guard has built a landing platform about 35' above the water.

Don Kasten WB4SST, a pilot, of all things. Goes right with his call letters. Don is starting a little ham business on the side to make tone encoders for FM.

There is a wire ladder hanging down from this platform. Since the cliffs are undercut from ten to thirty feet at sea level, utmost care has to be taken in approaching the ladder. One mistake and a swell can shove your dinghy under the cliff and the inrushing sea will smash it and you, spitting out the whole in a shower of spray that goes out about 30 feet.

As we approached Lulu Bay we noted with dismay that the tie down buoy which used to be there had been removed. The bottom is deep and smooth, making anchoring very difficult. The cliffs go straight down about 80 feet under the water and the bottom falls off rapidly to 300 feet or so. The seas were much too heavy for the big boat to get near the ladder and the cliffs. We would have to use the tiny dinghy to go ashore.



Chaz, anxious beyond all description to get his feet on solid ground, went in with the first dinghy trip. Even the spectre of the ladder, which is not at all easy to climb, didn't slow him down in his rush to get on shore.

As self-appointed official photographer for the trip I managed to get into the second trip to the ladder. After being up all night and shaken through and through for twelve hours, I was groggy but game. Somehow I got into the dinghy, meeting it coming up as the big boat went down a swell, grabbed my camera bag, and off we went to the ladder about 100 yards away.

The ladder is a bitch to climb. You have to put one leg around on one side and the other in front or else it will swing out from under you and you then have to chin yourself up the length of it; if you do it right you do get a good workout and some bruises on the legs, but at least you can make it in a minute or so instead of having to rest two or three times on the way up. Just grabbing the ladder takes coordination. If you grab it and hold on while a swell is down the next wave will come up and soak you. If

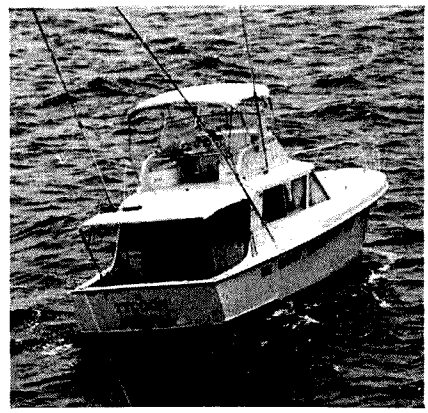
Bill Donovan WB4WMG of Atlanta.

Navassa comes up over the horizon dead ahead, proof of good navigation by the skipper.

Lulu Bay, the only landing on Navassa, a pork-chop shaped island about three miles long with no beach whatever.

you grab at the peak of a swell and don't hold tight the boat is suddenly six feet below you.

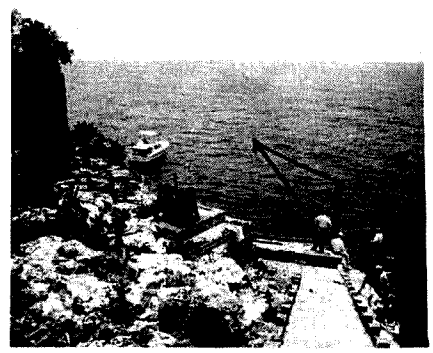
The island wasn't as steady as I wished. I made it to the top of the ladder, my cameras followed me up on a line, and I stood there gathering my wits – or at least half of them. The island was not pitching and rolling as much as the boat and that was nice. Chaz was there, a bit of color beginning to appear around the edges.



Cameras slung over my shoulder, I headed along the cliffs to get into a good spot to take pictures of the landing operation. The cactus had grown a whole lot since my last visit and I soon found myself stopped to pull off big bunches of it. Balls of cactus clung to my pants, my shoes, everything. Luckily I had worn gloves to climb the ladder and they made it easier to pry the damned stuff off. Only a few thorns went through into my fingers – and broke off.

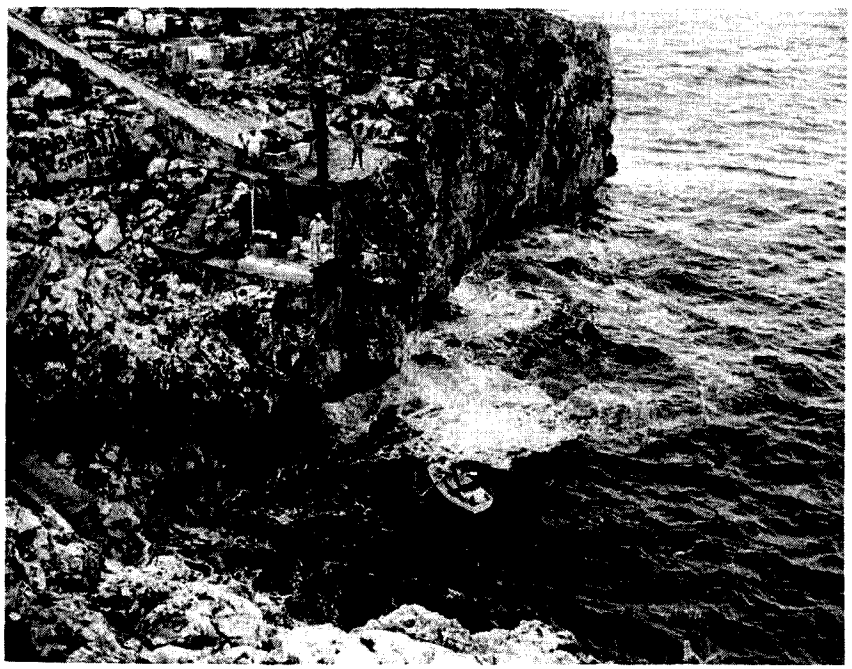
Since I knew that the fellows would thank me in the long run if I spent most of my time taking pictures of them working rather than stopping the pictures to lend a hand pulling all that gear up the cliff, I tried to ignore the growing chorus of requests for me to come and lend a hand. You know, they reacted the same way the last time I came to Navassa! As the suggestions became a little more pointed I did some token work, huffing and puffing a lot, talking a good deal about how old I am, how often things like this lead to serious heart attacks for those unused to heavy work in the hot sun, and musing over the reaction of the 2000 or so life subscribers to *73* and their reaction if sheer laziness on the part of a couple of expedition members should cause me to expire.

I sure did get an awful lot of pictures.



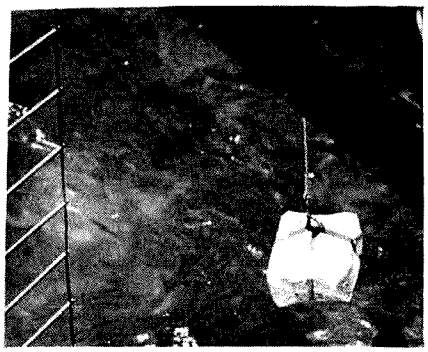
Along about 3 PM most everything was ashore that we would need and Don WB4SST was hard at work trying to decipher the instructions that came with the all band vertical antenna. The hot sun, lack of sleep, and continuous seasickness did help to make most of us a bit crabby. Neil helped with this a whole lot by issuing conflicting orders, and generally rubbing everyone the wrong way with a skilled hand.

Ray Cobb K4PGM, our gourmet cook, got his job off to a flying start by unpacking the grape jelly a little quickly. It dropped and there was Ray in grape shoes. Fortunately he had thought to bring a spare jar of jam, so all was not lost. The strawberry jam did the ten of us fine.



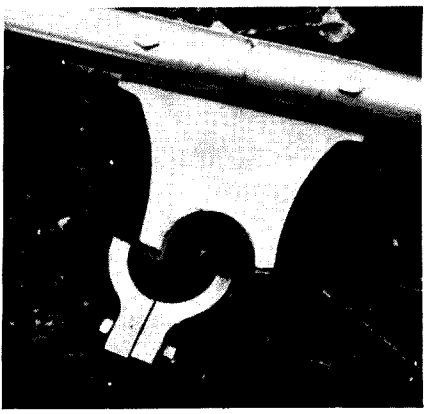
The Tycoon.

Two of the rigs were set up in short order – Heathkit sets. The triband beam was the next order of the day. It was taken out of the box and three fellows set about trying to get it together. Steve Smith WA4VWV tried to make heads and tails out of the instructions. One casting was cracked when the package was opened. The



The Tycoon at anchor a couple hundred yards off from the cliffs. The loading boom and winch were rusted solidly into place and not usable, so everything had to be hauled from the dinghy to the platform by hand line.

castings which were supposed to hold the reflector and director to the boom were a little small and couldn't be fit to the boom. The cracked casting promptly broke when forced. Some tape saved the day with this. The element was taped to the boom.

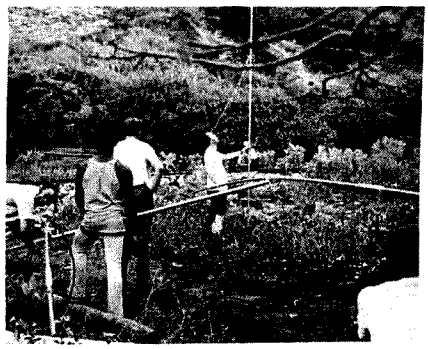


Hauling the gear and food up the cliff from the dinghy. Note graffiti all over the place such as the K4IA/KC4 on the side of the walk way and the old brick cistern building above the cliff. That gang sure must have brought a lot of paint.

One of the transceivers comes up the handline from the dinghy. Everyone held their breath hoping that nothing would go wrong at this critical stage of the game.

The worst blow of all was when Steve discovered that we had two director elements and no reflector. You can shorten a reflector and make a director out of it, but how to stretch a director? You don't. The result was a beam which we never had to turn at all. Oh, we tried turning it, but never could find out if there was any way to point it that was better than others so we just gave it up.

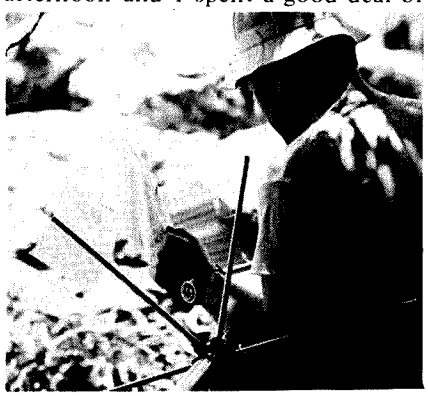
The casting which was supposed to hold the reflector on the tri-bander boom looked like this when we tried to fit it to the boom.



The next kick in the head was when the tribander had been assembled as best we could with the parts furnished and we put it on the end of the 18' mast. Four of us walked the mast up to about 45° when it folded at the top f the bottom section. So we ended p with a 12'' mast. This could not ave helped the beam a lot either.

So we used tape to hold the darned element to the boom. There were two directors and no reflector hipped with the antenna, so the beam didn't work.

Under Neil's direction the 75m antenna was swung a couple of feet below the beam. This had the benefit of wiping out the 75m operator whenever the tribander was being used. The 75m dipole wire was stretched out without being unwound, with the result that it took an hour or so to get the hundred or so kinks out of it. And so it went.



The rig that was to work with the tribander turned out not to work, so the Swan rig, which was brought as a spare, was set up in its place. Despite

Richard, one of the boat crewmen, looks on in wonder as Steve hooks coax to driven element. Others are setting up the guys for the mast – which promptly folded in half.

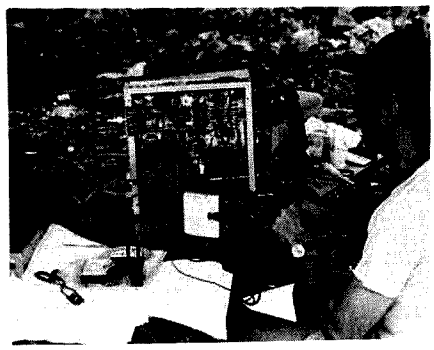
the antenna, it worked and the DX-pedition was on. The pileups built up immediately. All of us did a lot of operating during the weekend and most of us had a ball. It was reported that Neil had taken on the 20m CW station and had managed to work his way through 26 contacts in two hours. I found that I was running about three to five a minute on phone.

We got started operating late Friday afternoon and I spent a good deal of

Don trying to decipher the instructions for assembling the vertical.

the night operating and logging for others, mostly on 20m. I finally managed to get onto a cot set up under a big baobob tree about 5AM as it was beginning to get light. I had to coat myself with a half inch of bug repellant to keep off the swarms of mosquitos. About an hour later the first drops of rain hit me in the face. I yawned and headed to the operating area to help cover the rigs. On my last Navassa visit it had rained about ten minutes during the four days we were

Steve and Phil Latta W4GTS at work figuring out the tri-bander assembly instructions. They sure wish they'd made a practice run on this in Atlanta before getting to Navassa.



there. This time it rained a good half hour and it rained hard. So much for that night's sleep.

Neil set up a folding table as a work bench and opened up his 80 pound box of tools to see about fixing the ailing transceiver. Neil went at it fresh, having had a nice night's sleep in a tent, sleeping right on through the deluge. He needed his fresh for as he started to trouble shoot he found that

Call letters of some of previous ops were painted all over the place. It's no wonder the Coast Guard doesn't like to have hams visit Navassa. Our expedition did not paint anything whatever. Note that the KC4AF expedition in 1958 did not paint anything either.

his vtvm had gone west. He spent a good deal of the day fixing his vtvm. Fortunately he had brought along a back up vom which he used to service the vtvm. He managed to completely disassemble the unit while fixing it. We didn't hear what was actually wrong with the rig, so I suspect it was nothing serious. It was working by evening, thus missing only half of the expedition. Unfortunately, once the rig was fixed, Neil was again available to operate and the screams of anguish

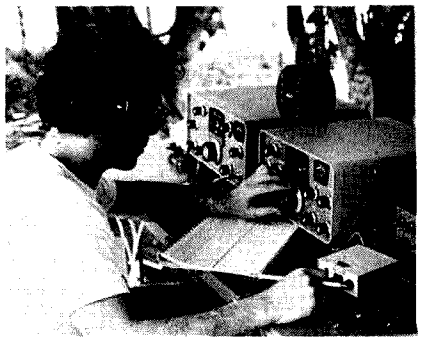
About half a day was spent servicing a vtvm.

from furious operators around the world could be heard echoing forth. There was serious talk of breaking the rig again just to get him off the air.

Neil was pretty crabby most of the time. He had been frustrated over and over. He had wanted to bring along a two meter repeater and set it up so we could all keep in touch via two meters when we walked around the island. This had been vetoed when it was found that the gear would cost 58¢ a pound to ship to Jamaica. He was put out when they made him leave his spectrum analyzer and Tektronix

Chaz operating while Rick, Skip and Don look enviously on.

scope at home. He wanted to bring along one spare for everything on the trip, plus a third for backup. And so it went.

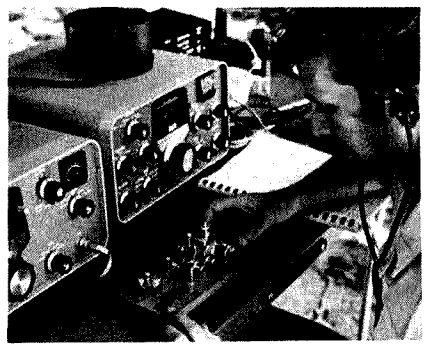


None of the fellows had been on a DXpedition before so they were not really prepared for the realities of the pileups. It is bad enough trying to handle the masses of stations that

The two generators were set up on a concrete patch that connects the landing area at Lulu Bay and the old Coast Guard acetylene building about 100 yards away. Station number two was set up right near the landing area beyond the generators.

want to work you when you have a good strong signal – when you are weak it is murder. One lousy lid with fifty watts and no brains in the States can drown you out. And once you cannot be heard there are enough idiots around to hold down your frequency for hours on end, each trying to be the very, very last in a tail-end race.

The Swan without a remote vfo made it difficult to try and work split frequency. And the weak signal made



Rick took care of most of the CW activity.

it miserable to work transceive. And so it went. Most of the time I worked by call areas, starting with the WB's, then the WA's the K's and the W's. This worked pretty well. Late in the game it came to me that I could do a bit better than this if I worked say three WB's, three WA's, three K's, and three W's in each call area, working my way around the areas a lot faster than when I picked up every single WB, no matter how weak or how bumbling. Next trip I'll try that.

Chaz operating while Bill Donovan logs for him.

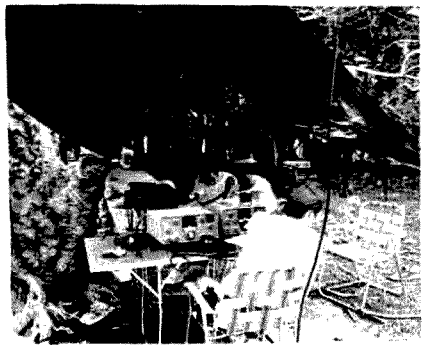
I managed to separate the DX stations pretty well by working them according to the number in their call. I had worked out this system in Jordan and it did well. Of course there is no real good answer to the s.o.b. who refuses to go along with this and calls without stop no matter what you say – like EA7IF. There was an HK4 and a PZ1 that drove hundreds of us up the wall too. I sure hope that Chaz does not QSL these stinkers. The next time I run an expedition there will be a place in the log to note that no QSL is to be sent for these inconsiderate

Ray took time out from cooking gourmet meals to paddle some CW.

crumbs. Yes, I know that we had a weak signal and that there are language problems – but is that an excuse for calling for an hour in spite of requests in their own language from neighboring stations to shut up and wait their turn?

One of the systems that worked very well for me and which I also developed while in Jordan was to have a couple other fellows with good signals move up or down the band and make up lists for me. This can flake

The Coleman stove had to work on regular gas instead of white gas due to a gas strike at Kingston. It managed, but had to be coddled. Here is Ray coddling the stove and coaxing it to turn out spaghetti and meat sauce.

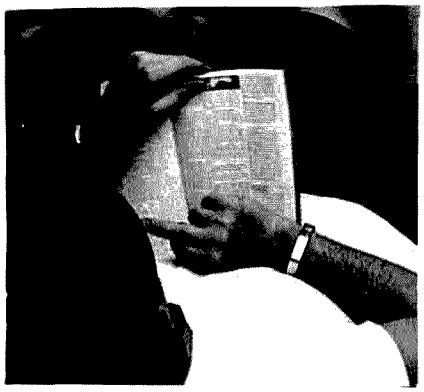


out if the band folds, but most of the time it works very well. The big problem for a DXpedition is getting the call letters through the QRM. A list fixes that.

At one time I had too many chaps making lists and I got about a hundred calls behind. This meant that some of the fellows on the list had to wait quite a long time for me to make it to them. I tried to speed everyone up as

Bill Smith has just learned that he is scheduled to log for Neil.

much as I could, but many insisted o spelling out their calls, even though already obviously had them – others gave their names and locations – etc. noticed that almost without exception that the German ops would be there even after an hour of waiting. The Japanese ops hardly ever gave up



Chaz operating while Steve logs 'em in.

They were right there, no matter how long it took and I worked dozens upon dozens of them, all in the S-2 to S-5 signal range. Without the list I would have only worked a fraction of them.

The band folded to Europe on Sunday morning as I was working my way through a long list – sorry about that.

Now and then someone would get mad and put a carrier on the channel to try and spoil things for everyone. I would stop everything when this would happen and explain to the chap

73 was the favorite reading material around the camp. It was the ONLY reading material around the camp.

that all he was doing was making life miserable for the many fellows that we were contacting and that I would simply change bands to move away if he persisted. This worked every time.

During off moments on Saturday I tried to take a nap on the cot, but the flies paid no heed to the bug repellant and were perversely persistent. There was no sleep. Along about one in the morning I sacked out and fell asleep. The Sunday morning rain started in about 3 AM and I was up again, getting my daily bath. By the time we left Navassa on Monday morning I calculated that I had managed about six hours sleep total from the time I got up Thursday morning. Excitement and nervous energy kept me going. I did manage to grab an hour or so of sleep on the boat trip back.

Nothing very rare was worked during the trip. The best I managed was 7Q7AA. Very little from Africa came through. A couple of 5Z4's made it. Not much else. It was a pity that we talking about KC4DX and wondering when we would come on. Every time they turned it from one to the other I broke in yelling "break!" After a half hour of this I was close to tears. I tried moving up the band and calling CQ. Nothing. Pretty soon I heard my old friend CO2DL talking to the W4JM roundtable aha, now I'll make it. I tried again to break the group; no luck. Not once did they ever shut up and listen for a weak KC4DX on channel trying to get through to them not one time! Two

did not have a couple of good beams along as we had had in 1958 when I last visited the island. That time we brought two beams, rotators and towers. We worked a JT1 last trip.

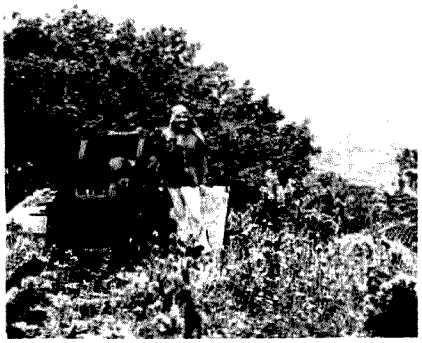
A short 75m stint was more than frustrating. I enjoy working DX on 75 and I had been looking forward to knocking off a good bunch of contacts on that band. The 75m station was set up next to the tribander and every time the other rig came on the 75m receiver dropped dead com-

Typical terrain on the island. It did not encourage casual strolling around. Some of those holes went down over thirty feet!

pletely. Okay, I would have to work through the difficulty and make contacts as I could. The 75m dipole was about eight feet off the ground, so I didn't expect a lot out of it. And the rig wasn't running a lot of power. But I didn't expect what happened.

A low end of 75m was fairly clear. I heard W4JM and some others on there of our group pulled me away from the rig, calmed me a bit, and got me to go to bed to cool off. I didn't make any 75m contacts.

Slow Scan DXpedition



Though no one on the expedition seemed overly enthusiastic about my bringing along a little cassette recorder so we could make some slow scan television contacts, one member, Neil, resisted to the last ditch. Even though I had brought along patch cords and different types of connectors so we could connect the tape recorder into

Part of being cook is doing the dishes. Ugh!

Ostentatious show of reading 73 to sooth a crabby publisher who has had damned little sleep.

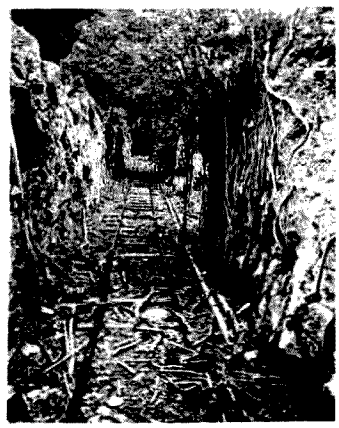
the mike and speaker jacks, they didn't match the ones on Neil's control consoles and there was absolutely no way that we could mate them. I found this interesting in view of his virtual radio store supply of spare tubes and parts which had enabled him to just about rebuild his VTVM the day before.

Well, no matter. Slow scan is simple to use and we don't even have to connect the recorder to the rig to make do. Before leaving home I set up a menu board with a KC4DX QSL on



Old tracks for mining cars.

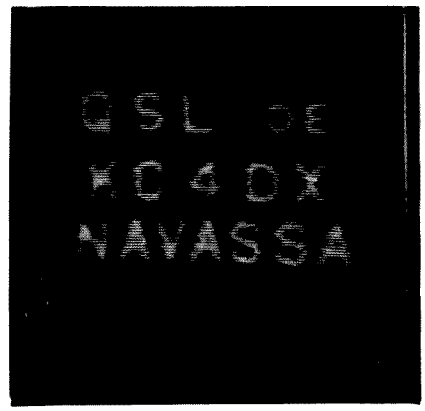
it and recorded the slow scan signal on a tape cassette. I brought along a second cassette for recording the incoming slow scan signals. Lacking the patch cords I decided just to put the transmitter mike up to the recorder speaker and do an audio patch. Ditto the recorder mike to the receiver speaker. I hadn't tried it before, but I figured it would work well enough. We weren't after perfection, only success.

I tired up one of the rigs – the one using the vertical antenna. I realized that I had a lousy signal for 10 AM Sunday morning, but that was what was available and I figured that enough fellows would want Navassa on slow scan to clear a channel. I figured wrong.

14,230 was busy with some W6TEZ and others trying to get a JA3 on slow scan. When I came on channel I was asked, not too politely, to get the hell off the channel so they could get their JA. My short fuse was lit. With bad grace I moved down a bit and worked W4MS – no strain – my pictures came through just fine. That was a relief. Eddy had no sooner made his contact for his country number 43 on slow scan than W8YEK called in. I was number 46 for Gene. I'm reasonably sure that Gene is leading in slow scan DXing.

The tape recorder system of working slow scan is not novel. Many slow scanners have only a monitor and use a tape recorded camera signal until they build or buy a scanner. Robot makes up tapes for their monitor customers – and any active slow scan-

Tracks go along cut about ten feet deep all the way across the top of the island. This facilitated their dumping guano and stuff into the cars from the surface.

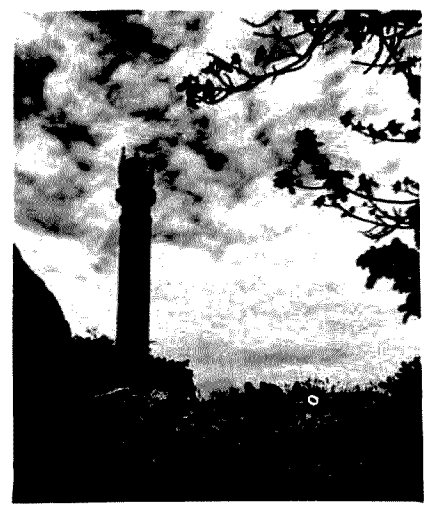


ner with a camera will help out and make tapes for newcomers. Buster W9WED uses a cassette recorder to make mobile SSTV contacts.

A few more slow scan contacts were made and I found myself out of customers. I moved back to the international slow scan channel and tried to break the group still struggling with the JA3, but to no avail. I moved back down the band and started working the thousands of sidebanders who wanted Navassa.

Late that night Glen W6KZL called on sideband and asked for a slow scan

The first glimpse of the lighthouse from the tracks.



Slow scan television QSL sent from Navassa via a $17 cassette tape recorder and received by W8YEK and photographed from his monitor. The el cheapo battery operated recorder does result in slightly quivery letters.

QSO. I whipped out the recorder and inside of about a minute we had that one buttoned up. In all ten SSTV two way contacts were made from Navassa – a new first, I'm sure.

In June I'll have the recorder with me and try for some slow scan contacts from YK1AA, JY1, OD5 and possibly even SU1IM.

The incoming slow scan signals were recorded and played back when I returned home. They came out just fine! I've since replayed them on the air several times to let fellows see how they came in on Navassa.

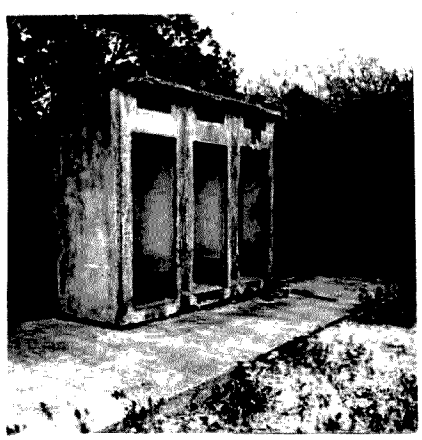
When you consider how terribly simple it is to take along a complete

The lighthouse.

slow scan setup on a trip or a DX-pedition, it is difficult to see why this should not be part and parcel of all future unusual operations. You need no camera – you need no monitor all you need is a tape recorder. My unit was one which I bought for $17, so you don't even have to have an expensive recorder.

On Sunday afternoon Skip K4TMA, an Air Force man, and I headed up the hill toward the lighthouse. We picked a poor trail for it and soon found ourselves struggling up a 30° slope covered with what

Wayne, Bill, Chaz, Skip and Steve rest at the bottom of the lighthouse.



looked like meteorites and cactus. The whole island is made out of swiss-cheese type rock, like a giant solid sponge. You have to watch every step carefully for there are holes all over the place. Some are only a foot or so deep, others go down thirty or more feet and could hold a horse. One unwary step and you are in deep trouble.

We finally got to the top of the plateau which covers most of the island and were met by Chaz Steve and Bill Donovan WB4WMG who had found an easier way up following an acytelene pipeline which had been built in 1962 to power the lighthouse. The lighthouse is now run on batteries which apparently are brought in by helicopter and the pipe line was no longer used. Pity, for they sure did a lot of work putting it in. I feel sorry for the Coast Guard men that had to work at that project.

The lighthouse was firmly chained so we couldn't get into it. We did explore the old lighthouse keeper's building next to it. The roof had burned off this building in the 30's but the cistern was full right to the ground level with water. In '58 it had had water, but we had to reach down about ten feet to get it. That was the time when we ran out of our own water and had to go to the lighthouse to keep from drying up and blowing away. The water looked a little stagnant so we boiled the first batch. This was a lot of trouble so we tried a glass of it on the least popular member of the group and waited to see if he died. He didn't so we all drank it right out of the cistern from then on without bothering to boil it.

This trip we had plenty of water so we didn't have to haul it back the mile from the cistern. Our boat stayed nearby so we were able to get in a lump of ice every day and have iced drinks – luxury. On the last trip the boat dumped us and then left us alone, going to Haiti for a few days to see about a leak, so we had no further supplies possible.

Though I have no complaint about the food on this trip, some of the selections seemed strange. For instance, we had along a rather good supply of powdered eggs rather than fresh ones. I forgot to ask why. It certainly wouldn't have been much trouole to keep fresh eggs on the boat and send in a dozen with the ice every day – or two dozen, for that matter. The powdered eggs came out excellently, spiced with some of those bacon bits – you know, the synthetic bacon. I would think we could have had fresh meat the same way, but instead we had packaged beef stroganoff. Again, it was fine – no complaint. But the whole works was a curious mixture of camping out away from civilization, all the while keeping civilization (ice) with us.

World's deepest privy? With a 400 foot hole under you, it is difficult to bring the necessary concentration for proper use of this fine Navassa facility.

While at the lighthouse I made contact via two meter FM (146.94, to be precise) with the base station and from there via 20m I contacted K6CKY/4 in Virginia for, I think, the first two meter relay DXpedition QSO. Always something, eh? We didn't need the repeater for the island is small enough so there was no problem in keeping in touch via the little Drake one watt TR-22 units.

Early Monday morning we turned off the generators and packed up to leave. The number of contacts had definitely fallen off, though I am sure that we could have gone for several more days on the bands working the thousands of European and Asian stations that missed us. Perhaps some day we'll be back again – probably with a much better antenna setup and a linear amplifier to make working out easier. I don't think there was more than one chap on the trip that wasn't thinking seriously in terms of going on another DXpedition as we moved the gear back aboard the boat. It was fabulous.

With serious work in sight, I headed for the safety of the adjacent cliff and started snapping pictures of those who were working. The seas were a good deal calmer than when we arrived so the operation went quickly. Even a calm sea at Navassa is something to contend with, so it wasn't all peaches and cream. The little dinghy bounced up and down about four to six feet as it came alongside the big boat, making the transfer of people and the heavier gear chancy. No accidents.

If anyone else is thinking of going to Navassa they may be encouraged to know that we left a nice triband beam there for them. We recommend that they bring along a reflector for it and a taller mast – and perhaps a couple of castings since the sun and weather may rot out the tape in a short while. There didn't seem to be any good

After three days of much operating and little sleep Don is a little groggy. He wore the cap to fake us all out. Don is now a jet pilot with the call WB4SST.

Phil Latta W4GTS of Atlanta, as seen on Navassa.

Phil W4GTS as seen by Atlanteans.

reason for bringing the remains of that antenna back.

The ride back was a good deal easier than the trip to Navassa and many of us were able to stretch out and get some sleep, at least for a couple of hours. No sickness this time. We did burn out one engine and had to limp back at half speed for the last few hours on the other engine. We just about ran out of fuel oil too, with only a spoonfull left when we docked. The engine quit as we maneuvered into place. Luckily we had "borrowed" some fuel from a passing boat at Navassa in exchange for replacing a fuse in their radio, or we might have had to go into port out by the end of Jamaica instead of heading directly to Kingston.

We all had a quick dinner at a local department store, the only restaurant open at 10 PM, and went off to a very deep sleep. Chris 6Y5CB and his attractive wife were there to meet us and guide us around. Most of us flew back to the U.S. the next morning, though a couple stayed on with their wives for a few more days vacation. By Tuesday night I was back at *73* six days away and another memory for a lifetime for me.

The trip to Navassa was so much fun that it put me back to the map of the Caribbean to see where else a small group might go that would be fun, reasonably rare, and not too expensive. I think I've got it. Would any of you readers like to try your hand at a DXpedition this fall? How about one to Baha Nuevo (HKØ) in late October to coincide with the DX contest? I figure that the whole thing can be done for about $500 per person with ten going. We would leave from Kingston on October 25th and set up on the 26th. The big push would be on the 27-28th, and back on the 29th to Kingston – to the U.S. the 30th. One week of great fun.

This time we would have a place to sleep on the boat going over for it would take about 24 hours to sail that distance from Kingston. We would have two transceivers with beams, one with a good linear, and one spare transceiver with more modest antennas. The beams would be complete with rotators and short towers. I think I can plan the trip and arrange for the equipment. It will be hard work at times, so strength and stamina are required. Any takers?

SLOW SCAN TV: INTRODUCTION AND BASIC PRINCIPLES

You are about to enter the wonderful world of amateur slow scan television. Imagine yourself sitting in front of a radio receiver with a slow scan television monitor plugged into the headphone jack. The screen shows SMØBUO in Stockholm operating his rig from his lakeside cabin. You turn your dial to another frequency on the 20 meter band and observe WØLMD exchanging circuit diagrams with W4TB in North Carolina. These things are now possible with slow scan televsion. It has not always been this way, so let us turn the slow scan history pages back a few years to see how it all began.

In 1958, Copthorne Macdonald, a young engineering student at the University of Kentucky, began an investigation into the possibility of reducing the bandwidth of a wideband television signal to such a narrow spectrum width that it could be sent over a voice communication system. This meant that a 3 MHz television signal had to be reduced to 3 kHz signal – a 1000 to 1 reduction in bandwidth! Macdonald eventually designed a television system that met these requirements. This system used an AM subcarrier, with picture information transmitted as amplitude variations of a continuous tone of constant frequency. The old 11 meter band was used to transmit test pictures since that was the only HF band authorized for picture transmission. The AM subcarrier system proved successful, and circuit details were published in August, September *QST* (1958). Unfortunately, before the slow scan pioneers of that period could build equipment, the 11 meter band was allocated to the Citizen Band Service.

Slow scan television was now limited to frequencies of 50 MHz and above. However, under special authorization from the FCC, it was possible for Cop to perform tests on 10 meters for short periods of time. It was during one of these test periods that Cop WA2BCW, by transmitting "blind" over a period of 30 days, was successful in sending pictures across the Atlantic Ocean to John Plowman G3AST. These tests, and the pictures received in England, were described in March *QST* (1960).

Their imaginations sparked by the transatlantic tests, other amateurs soon began to explore SSTV. Soon, a small group of SSTV enthusiasts were exchanging SSTV audio tapes, and investigating a variety of circuits and standards. An FM subcarrier system was developed (January, February

Fig. I-1. Picture of W9CNW, sent from W9NTP to VK3AHR, 10,000 miles, on 20m. 2.5kHz bandwidth.

QST 1961), and it proved superior to the AM subcarrier system due to its greater immunity to interference from QRM and fading. Since none of the early experimenters were close enough geographically to exchange pictures on the 6 meter band, tests were confined to closed circuit systems, tape exchanges or transmission over phone lines.

During this time the slow scan enthusiasts were attempting to get slow scan (SSTV) permitted on the HF bands. Petition after petition was written, but no FCC action resulted. Macdonald, now WAØNLQ, enlisted the help of several hams in Washington and succeeded in getting a special test period set up at the Rocky Mountain ARRL Convention in Colorado to test the possibility of interference to other hams. W3LJV, W7FEN, WAØNLQ, W9NTP, and WØITB participated in these tests, and for three days visitors at the convention saw themselves on slow scan television either going out over the air or their image being returned over the air from far-off places via retransmitted tape-recorded pictures. It was hoped that other amateurs would hear the signals, form an opinion about their nature and interference potential and let their feelings be known through proper channels. It was during this test that the well-known picture of W9CNW, Figure 1-1, was recorded in Australia by VK3AHR with the scheduling help of W9TCT. This test was described in September 1966 *QST*.

As a result of the Rocky Mountain Convention tests, Macdonald convinced both the Navy and the FCC to authorize special SSTV tests on the HF bands. The primary goals of these tests were twofold: to improve the techniques and equipment developed for STTV, and to provide visual communications for personnel wintering over at McMurdo Sound, Antarctica. Fifteen stateside amateurs were authorized to participate in these special tests and Macdonald provided a camera and monitor to KC4USA/NØICE for use in Antarctica. Despite erratic propagation conditions, excellent pictures were often exchanged between Antarctica and the States, some of which were shown in *QST* Feb. 1967, page 77. It is interesting to note that the Navy to this day continues to support the development and use of slow scan, and has recently authorized W4ABY/NØAAJ and W4UMF/NØXTV to exchange SSTV pictures with the *S.S. Hope*.

An FCC proposal of rulemaking permitting SSTV operation on the HF bands was published in November, 1967 *QST* with one month allowed for reply. After this reply period, several amateurs – W2PMV, W9VZL/3, WAØNLQ and W9NTP – went to Washington to review the 30 letters of opposition. Very few of these letters were strong in their criticism, but some letters expressed fears that needed to be studied and resolved. After eight hours of study and discussion these amateurs spent that evening at the home of W9VZL/3 where they wrote answers to the criticisms. This small group felt sure that a slow scan television allocation was just around the corner.

At this time incentive licensing was getting quite a bit of attention by the ham world, ARRL, and the FCC. After about a year with no FCC slow scan television action, fears began to grow again. By making inquiry through the proper channels, we were told that SSTV would be a part of the incentive licensing proposal. The rest is history.

During the summer of 1968, while on a mobile DXpedition to Central America, one of your authors heard the famous words from W7FEN: "Slow scan is authorized on HF." That is how it all came about. Those of you who now enjoy the luxury of operating your slow scan gear have these early pioneers

to thank. Copthorne Macdonald is the inventor, and by his persistent interest finally perfected the system and obtained FCC action to use it.

Slow scan television can be transmitted in all of the advanced and extra portions of the amateur bands. Its bandwidth is confined to that of a voice station which is interpreted to be 3 kHz for single sideband transmission. The 160 meter band is excluded but all the phone portion of 10 meters and VHF and UHF can be used by General and higher classes of amateur licensees. It is of interest that SSTV received more band allocation from the FCC than any of the petitions ever requested.

This is the history of slow scan television. Today hundreds of amateurs throughout the world – in Russia, England, Sweden, Italy, Greece, South Africa, Colombia, Venezuela, Guadeloupe, Puerto Rico, Nicaragua, Canada, Alaska, Hawaii, New Zealand, Australia, Japan, Brazil, Southwest Africa, Belgium, Germany, the continental United States, a total of 28 countries – routinely exchange pictorial information via slow scan television on the 80 through 10 meter bands. And what started as a senior project for a young undergraduate student at the University of Kentucky is now one of the most exciting communications modes within the amateur service.

Basic Principles of Slow Scan TV

Let us explore this new amateur television that was specifically designed by hams for picture transmission on the high frequency bands. Instead of 3 MHz being available for ATV, as in UHF, we are restricted to a 3 kHz voice bandwidth in the HF amateur bands. The bandwidth of a conventional television signal must be reduced by a factor of over 1000 for slow scan. It becomes obvious that both the horizontal and vertical frame rate must be reduced to as low a frequency as possible in order to reduce the bandwidth from 3 MHz to 3 kHz. Resolution of the picture is a prime consideration in choosing the standards Home television viewers may feel that all 525 lines of commercial TV are needed for good TV pictures, but with narrow i-f's, poorly adjusted interlace and other deteriorating factors the actual resolution of a home television receiver is reduced to about 250 lines. As an example, 80 lines per MHz is the computation formula used for estimating the resolution of a 3 MHz i-f system. This is a resolution of only 240 lines. If we now consider that viewing will be done on a small cathode ray tube (available radar tubes), the tube screen size becomes a limiting factor due to beam focus. Everything being taken into consideration, 120 lines were chosen as the maximum number of lines for slow scan TV. It will be shown later that if 240 resolution lines are desired, they can be transmitted in an interlaced format for increased resolution, but such a picture cannot be viewed directly and must be photographed for the increased resolution to be realized in practice.

The vertical frame rate should be as slow as possible consistent with the storage time of the viewing tube. As far as the average ham is concerned, this means the use of a surplus P7 phosphor radar tube since available storage tubes are prohibitively expensive. Tests run over several years showed that 10 seconds was the maximum time of a frame that would permit viewing the frame on a P7 tube with a viewing hood in a normally lighted room.

It is a real advantage to use a horizontal line frequency that is related to the power line frequency. After sampling many viewer opinions and running laboratory tests it appeared that 15 Hz (i.e., 60 Hz divided by 4) was a good choice. 120 lines at 15 lines per second gives an eight-second vertical frame rate. Since these standards have been used by slow scanners in all 60 Hz power countries, it is hoped that they will be maintained indefinitely.

One thing that remains to be demonstrated is the video bandwidth of the slow scan system. Since an aspect ratio of 1:1 seems the most desirable to fit a round radar cathode ray tube, the horizontal resolution should equal the vertical resolution. There are 120 lines division in the vertical direction; therefore, there should be 120 division in the horizontal direction. This is shown in Fig. 1-1. For simplicity assume that every other spot is black alternated with white spots If these spots

Fig. 1-1. One line of slow scan TV.

are scanned, the output will be a square wave which is formed out of one black and one white spot. This waveform generates 60 complete square waves or cycles in 1/15 second or 60 x 15 = 900 Hz. This means that the maximum video bandwidth is approximately 900 Hz. This analysis is approximate, but is adequate for easy comprehension.

All that remains to be shown is the requirements of the sync pulse standards. We now have a 120 line picture being generated every eight seconds which generates a bandwidth of 900 Hz. Each line must be locked or synced, and each eight-second frame must be locked or synced. In order to choose the proper length sync pulse consideration must be given to the composite spectrum (sync, pulse and video) and how it is combined to be transmitted with good fidelity.

It has been shown that a video bandwidth of 900 Hz, is adequate to reproduce the slow scan 120 line picture. Since the line rate and frame rate is extremely low frequency, a great amount of the video energy is near zero frequency. This means that amplifiers and modulation devices must operate near the dc level. This, of course is impossible since phase shift and drift would cause much deterioration in the picture. The problem can be avoided if the 900 Hz video is modulated on to a subcarrier placed within the 3 kHz FCC allocation for slow scan televison.

This subcarrier is placed at 1500 Hz. In the early days of slow scan, the subcarrier was amplitude-modulated, but extensive testing proved that AM noise created many problems. At that time, it was decided to go

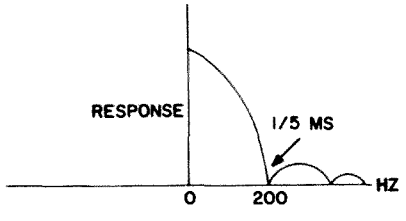

Fig. 1-2. Spectrum of video sync pulse.

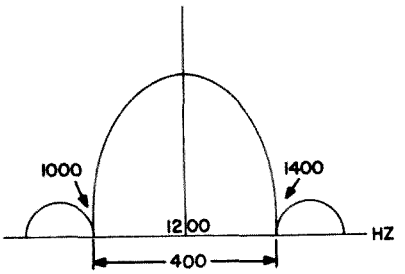

Fig. 1-3. Subcarrier spectrum of video sync pulse.

to an FM subcarrier. Today, the subcarrier operates at 1500 Hz for black video and increases in frequency to 2300 Hz for white video. These frequencies were chosen due to extensive experience with FM subcarrier facsimile transmission.

The sync frequency of 1200 Hz was chosen and represents blacker than black so that the raster is blanked during retrace. In order to separate the spectrum of the sync pulse as much as possible, the length of the pulse is made five milliseconds. Analysis showed that a five-millisecond pulse has a base video bandwidth of 200 Hz as shown in Fig. 1-2. When the sync pulse is modulated or gated on to a 1200 Hz sinewave, the bandwidth is 400 Hz, centered around 1200 Hz as shown in Fig. 1-3. Note that the major part of the sync spectrum does not fall into the major part of the video spectrum which swings upward from 1500 Hz. Finally, the vertical sync pulse is made much wider than the horizontal sync pulse in order to integrate or separate the two pulses. The vertical pulse was made 30 milliseconds long or about ½ a horizontal line. There are some who feel that this pulse should be made a bit longer. This would provide a better vertical sync pulse separation and noise immunity. Most monitors will tolerate longer vertical pulses so there is some room for experimentation on this point.

Let us review the standards for slow scan television:

	60 Hz Areas	50 Hz Areas
Horizontal line rate	15 Hz (60/4)	16 2/3 Hz (50/3)
Vertical frame rate	1/8 Hz	1/7.2 Hz
Horizontal pulse width	5 milliseconds	5 milliseconds
Vertical pulse width	30 milliseconds	30 milliseconds
Sync subcarrier frequency	1200 Hz	1200 Hz
Black frequency	1500 Hz	1500 Hz
White frequency	2300 Hz	2300 Hz
Overall transmission BW (SSB)	3000 Hz	3000 Hz

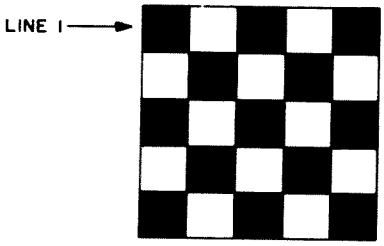

Fig. 1-4. Checkerboard pattern for slow scan transmission. The video signal and sync signals are shown in Fig. 1-5.

As a visual example of pattern generation, consider the following black and white SSTV transmission (shown in Fig. 1-4).

The video and sync signals are shown in Fig. 1-5.

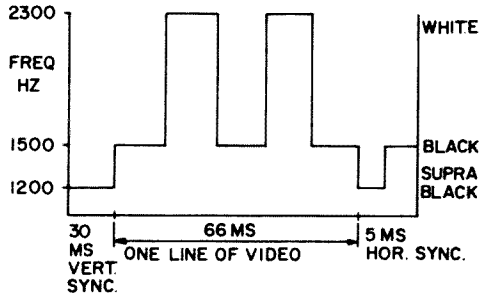

Fig. 1-5. One line of composite sync and base video.

The composite FM subcarrier signal is shown in Fig. 1-6. The composite video signal consists of a midrange audio tone ranging from 1200 to 2300 Hz and is processed in the transmitter and receiver just like a voice signal. If you doubt that a quality picture can have such a restricted bandwidth, visit a slow canner and watch pictures produced from an inexpensive cassette recorder operation at 1 7/8 r.p.s.

Most important in a slow scan television station is the monitor. The photograph of the original slow scan electrostatic monitor is shown in Fig. 1-7. This Macdonald monitor was described in March 1964 *QST*

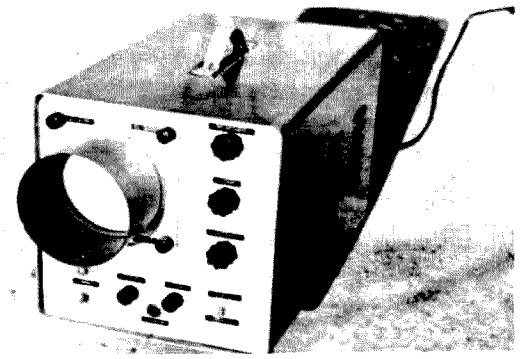

Fig. 1-7. Photograph of original Macdonald monitor (see March 1964 QST).

and this design has become the most reproduced piece of slow scan gear design ever published. This monitor has become the workhorse of slow scan TV, and it is still a favorite by slow scanners who prefer working with tubes.

The principle of all slow scan monitors is the same. Since the audio signal coming from the headphone jack of a radio receiver is audio FM, some means of FM detection must be used. A limiter is required to help eliminate much of the AM noise and QRM that is present on the HF bands. This limiter passes the clipped signal to an audio discriminator. This discriminator can be designed in several ways. The original Macdonald monitor uses a single-sided discriminator, but later in this book several other types of discriminators are described.

The discriminator changes the FM audio signal to an AM signal. It is important to note that the waveform is still made up of the subcarrier centered at about 1500 Hz. In order to recover the 1200 Hz sync signal a tuned circuit sync discriminator can be used to accentuate its amplitude so that the vertical and horizontal sync pulses can be recovered by threshold detectors.

These AM subcarrier signals will require rectification in order to produce the base

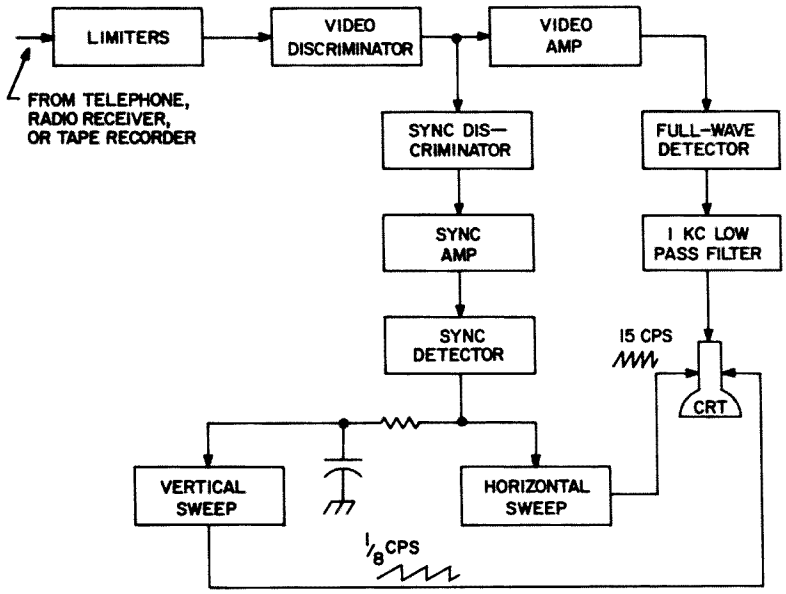

Fig. 1-8. Block diagram of a slow scan TV monitor.

video and sync signals that were generated by the slow scan camera or flying spot scanner. Usually full wave rectification is to be preferred since the low pass filter following the sync and video detector can more easily filter the subcarrier components if they have been doubled in frequency by full wave rectification.

Finally the deflection circuit (whether it is electrostatic or magnetic) is controlled by the recovered sync pulses to produce a raster on the cathode ray tube. The recovered and filtered video is now applied to the Z axis of the cathode ray tube to produce a slow scan picture. A block diagram of the slow scan monitor is shown in Fig. 1-8.

The generation of a slow scan television picture can be done in several ways. The simplest method for the transmission of slides, photographs, and circuit diagrams is the flying spot scanner. There are two designs of the flying spot scanner shown in later chapters of this book.

To utilize the flying spot camera to produce TV signals from film negatives or positives, it is necessary to generate a raster. A raster results when a sawtooth electrical signal is connected to the horizontal and vertical plates of a cathode ray tube. The two sawtooth voltages applied to the horizontal and vertical plates differ in frequency; so for one cycle of vertical deflection, several hundred deflections occur in the horizontal direction. The grid of the cathode ray tube is adjusted to produce a constant brightness spot on the face of the tube. The overall result is a white illuminated square or rectangle on the face of the tube made up of several hundred very nearly horizontal lines.

A flying spot raster on a home TV set can be produced by turning the contrast control fully counterclockwise until no trace of picture results. The brightness control is then adjusted clockwise until a white constant brightness rectangle results. This image is called a flying spot raster. A similar white rectangle is produced for slow scan television, but from different frequency sawtooth voltages. How do we produce a TV signal from this raster? It is important to remember that the raster has been synchronized in both horizontal and vertical directions by a timing circuit that starts the beginning of each sweep. The flying spot or beam is therefore in a precise location on the face of the cathode ray tube at any instant of time.

If a transparent negative or opaque positive picture is placed directly on or near the face of the tube, the light that passes through the transparency or that is reflected from the opaque photograph will be modulated by the density of the

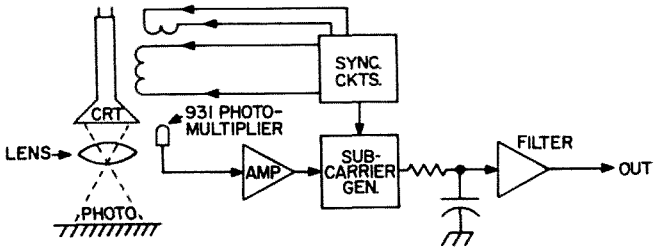

Fig. 1-9. Simple magnetic flying spot scanner.

photograph. It is now possible to place a light sensitive device (photo-multiplier) in the front of the tube, and the resulting electrical signal called video is synchronized automatically with the flying spot raster. The pulse sync signal is combined or added to the video to produce a signal that can be used to paint a picture on the screen of a distant TV set. It is important to remember that the sync signal always occurs when the beam flys back to its start during retrace; therefore, the video is not affected. A block diagram is shown in Fig. 1-9.

The principle of the flying spot scanner is useful for both fast and slow scan. Commercial TV stations have used FSS for advertising breaks. In the case of slow scan, the TV signal must be further processed before transmission. The video frequencies are so low that a subcarrier is needed to help the transmitter pass the slow scan video.

The slow scan enthusiast has several very good live cameras to choose from. Originally when Macdonald designed the shuttered 7290 slow scan camera, vidicons were given out by Westinghouse for experimental uses. Slow scan has grown greatly since it has become FCC-authorized in the Advanced and Extra class amateur phone segments.

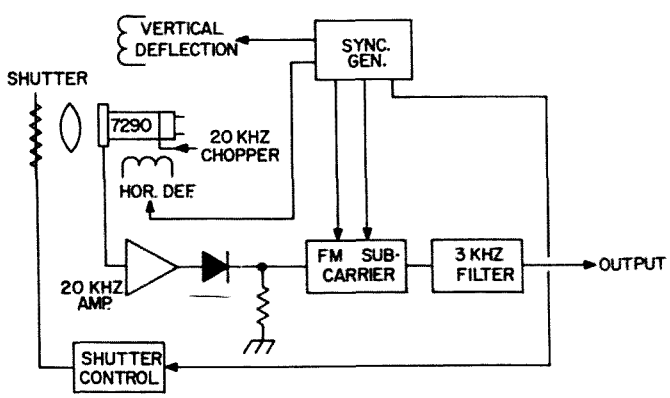

Fig. 1-10. 7290 shuttered camera.

Free vidicons are no longer available but can be purchased from the same source for $100. This price is far below the selling price of this vidicon for commercial use. The slow scan 7290 vidicon target can hold an electrical image for several seconds once it has been exposed to an image. In the 7290 SS camera shown in Fig. 1-10, an electrically-operated shutter exposes the target for about 1/30 second and then the image is electrically scanned for the next eight seconds. Similar to flying spot scanners, the vidicon beam must be swept in horizontal and vertical directions by the 15 Hz and 1/8 Hz sawtooth voltages to produce video.

The signal from the 7290 vidicon target is a very low frequency audio signal and requires much amplification. Audio frequencies near dc are very difficult to amplify because of limitations of coupling and by-pass capacitors, so a technique of chopping is used to electrically change the signal into an ac wave. A 20 kHz sine wave applied to the vidicon grid will turn the scanning beam off and on at this rate so that the small target signal can be amplified as a 20 kHz signal. Once the amplification is completed, the 20 kHz signal is rectified and the resulting signal is the amplified low frequency video or audio signal desired.

The vidicon is provided with the dc operating potentials usually needed and provision is made to blank the vertical and horizontal beam during retrace.

Due to the lack of 7290 vidicons, early slow scan pioneers tried to substitute ordinary fast scan vidicons such as the 7735A and 7038. Contrary to the opinion of those acquainted with the chemical and electrical make-up of these tubes, some slow scan hams were able to get reasonable pictures with *open shutter* operation. K7YZZ and WB8DQT have investigated this type of picture generation thoroughly, and have provided many good pictures on the slow scan net.

About this same time slow scan hams in Europe (such as SMØBUO) were successful in using plumbicons in the Macdonald circuit in the open shutter mode. This proved to be very successful and hams such as W4YHC,

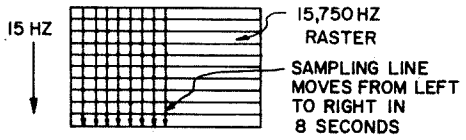

Fig. 1-11. Sampling method of producing a slow scan picture.

W7ABW WØLMD, and others have produced some excellent pictures using the Phillips plumbicon. These tubes are available as pull-outs from color cameras here in American and are available at TV stations in some parts of the country. Plumbicons, with their relatively high target resistivity are quite effective at slow scanning rates and represent an excellent alternative to the 7290 in the open shutter mode. Last but not least comes what the authors consider to be the best type of slow scan camera – the sampling camera. All of the above cameras (with the exception of the 7290 camera) require open shutter and therefore the subject being televised must remain nearly immobile for the eight seconds. In practice this is not very difficult and contributes to some of the fascination of slow scan TV in which special effects can be staged.

In principle a sampling camera operates like sampling oscilloscopes. The operating principle is based on the fact that the picture being sampled does not change over the length of time that it takes to sample moving fast scan frames. In this case, the time is eight seconds. Assume that a fast scan camera is operating with the following standards: vertical frame rate – 15 Hz, and horizontal line rate – 15,750 Hz. Note that a normal fast scan camera operates with a 60 Hz field or frame rate!

It is assumed that the video will be sampled at every line crossing as shown in Fig. 1-11.

By slowly moving the sampling point to the right at a 1/8 Hz rate, 120 vertical lines are formed. A slow scan sampled picture is generated in this way. This picture is on its side and the electrical signal needs to be filtered, but it is identical to slow scan pictures produced in other ways.

From a circuit designer's viewpoint, the functions that need to be generated in a sampling camera are as follows:

1. a 15 Hz sawtooth sweep voltage locked to 60 Hz mains.

2. A 1/8 Hz sawtooth, preferably locked to 60 Hz mains or to the 15 kHz horizontal sweep voltage.

3. A 15 kHz sawtooth to sweep the fast scan raster. This sweep does not necessarily need to be locked to other time bases and is available from the fast scan camera.

4. A circuit that provides the timing necessary to do the sampling that moves in time across the raster.

A block diagram is shown in Fig. 1-11.

Part II, next month, will cover popular SSTV circuits.

A Versatile Premodulation Speech Processor

Peter Lovelock W6AJZ
235 Montana Avenue
Santa Monica, CA 90403

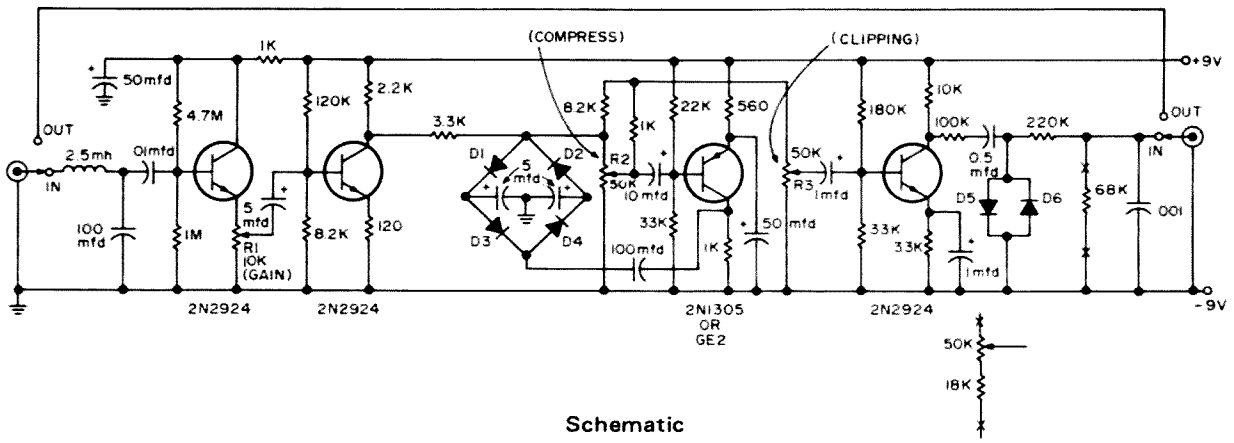
Since the early 1940's, when audio clipping first appeared as a method of overmodulation prevention, premodulation speech processing has been the subject of ingenuity and controversy. As a means of increasing the "talk power" of AM transmitters, it gained considerable popularity. More recently the audio compressor has almost displaced the clipper due to its inherent low distortion. For sideband applications it has been demonstrated that heavy premodulation speech clipping is unsuitable[1],due to the transients produced by heavily clipped peaks.

While a number of systems for clipping the sideband envelope have emerged, these require either breaking into existing transmitter circuitry (unacceptable to many owners of commercial units), or the use of a complex and expensive external unit.

The simple solution for SSB operation is still the speech compressor. In the past several years the author has breadboarded just about all of the transistorized compressor circuits published in the ham press, and tried them out on the air with varying degrees of success.

The two major limitations in compression applications were found to be (a) difficulty in maintaining close to 100% average peaks without initial syllables overshooting, and causing bad flat-topping; (b) excessive mike sensitivity when using maximum compression.

Since all compressor circuits utilize some form of feedback control of gain, it follows that there is a finite time constant involved in controlling initial input peaks. Even if this "attack time" is very short, the first syllable following a pause can result in a substantially higher peak than those immediately following. If compressor output is reduced to maintain initial peaks below the 100% level, then compressed peaks will be well below the transmitter maximum output capability.



In addition, the gain of the compressor is not proportional to the input, but varies in a non-linear manner, ideally logarithmically. Thus weak sounds receive considerably more amplification and when 20 db of compression is applied, mike sensitivity will increase as much as 10 times that of normal. Unless the operator enjoys the advantage of a soundproofed studio, the resultant background noise and room echo can be very undesirable. In actual practice with the normal ham-shack environment, the amount of compression must be held well below the maximum attainable, and the benefit obtained is something less than spectacular.

Together, both the above limitations tend to reduce the effectiveness of compression. Results of trying different circuits had been disappointing in comparison to the added punch achieved with good clipping to an AM transmitter.

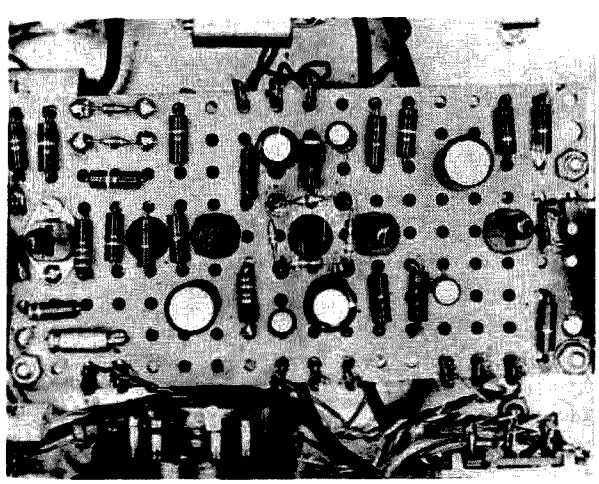
In reviewing both types of circuits, it was decided to try and combine the advantages of each. Actually this is not a new approach, since broadcast stations have long applied a combination of compression to maintain constant program level, followed by moderate clipping to positively limit overmodulation peaks.2 a number of published circuits were tried in different combinations, with the following performance requirements as a target:

Compression: 0 to 20 db, adjustable.
Clipping: 0 to 10 db, adjustable.
Hi-Z input and output.

The final circuit shown is based upon a

Schematic

compressor design by W. Henry[3], and a clipper circuit appearing in an issue of 73 [4]. The combination allows the optimum mix of compression plus clipping to be applied. Either compression or clipping may be used alone if desired for other than SSB applications.



A brief review of the circuitry shows that Q1 is a conventional emitter follower, providing a theoretical input impedance of 250K. This figure will be somewhat lower, dependant upon the exact Beta of the transistor used. At any rate, it will be in excess of 100K, providing the desired load for most Hi-Z dynamic or reluctance microphones.

Q2 and Q3 comprise the compressor section, which has excellent control characteristics, while being able to handle an unusually large range of input signal without overloading. Utilizing the characteristics of diodes D1 and D2 as a variable attenuator, controlled by a DC bias current provided by D3 and D4, the wide range of attentuation available results in almost complete cut-off of output in the presence of excessively strong inputs. Q2 functions as a conventional amplifier, while Q3 provides variable control signal which is rectified by D3 and D4. A unique resistive network acting in conjunction with the compression control R2, maintains virtually constant max peak output, regardless of the setting of the compression control. Time constants in the original circuit, resulted in a release time of approximately one second, consistent with tape recording applications. Time constants were modified to produce a release time of about 100 miliseconds, in order to closely follow the syllabilic rate.

Compressed audio is fed to the inp ut of Q4 via the clipping control R3. Q4 functions as a straight amplifier raising the level to that required for clipping by diodes D5 and D6. The 100K resistor in series with the clipping diodes prevents them from loading down the output of Q4. With the clipping control set to maximu, peak output from the compressor section will be clipped about 10 db. The RC network following the diodes provides a roll-off above 2,500 hz, and filters harmonic components created by the clipping.

Construction

Most everyone has a favorite approach to the construction of a device like this, and the processor has no critical requirements as to layout, providing that normal good practices are followed. The prototype was assembled on a 5" x 2½" piece of perforated board, utilizing good mica filled transistor sockets to permit trying various transistor types. For more permanent construction, perforated board with .062" holes is recommended, using flea clips for mounting com-

ponents, including transistors. Transistors of the economy type were chosen, but other types with similar characteristics may be substituted if they are available. Diodes D1, D2, D3 and D4 should be the types shown to obtain the right attenuation characteristics. These are now inexpensive types and readily available from leading distributors. Diodes D5 and D6 are particularly recommended for their clipping capabilities, though other silicon types will work. The 2.5 mh input choke is considered a must. Some early reports of distortion prior to incorporating this choke, proved to be due to rf feedback. The additional gain of this unit makes it particularly susceptible to rf pickup on higher frequencies.

The output of the processor is about 150 mv peak, which is quite a bit higher than the average mike level. In most cases, however, this can be compensated for by the transmitter mike gain control. In those rare instances that it cannot, or if the operator desires to retain the same mike gain setting with the processor in and out of circuit, the optional output attenuator may be substituted for the 68K output resistor.

If the processor is to be used only with a microphone in the -45 db to -60 db range, input control R1, is not absolutely necessary and may be replaced with a fixed 10K ½ watt resistor. However, if high level inputs, such as phone patch or tape recorder are contemplated, the input control will be useful to prevent overdriving the base of Q2, and should be set so that no distortion occurs. For mike use the input control may be left at maximum.

The clipping control R3, and the output attenuator (if used) need only to be set up once for a given mike and transmitter. These controls may therefore be incorporated as screwdriver adjustment types, leaving only the compression control for panel adjustment, so that compression may be changed to suit individual operator voices and conditions.

Using the Processor

Much of the comment that has been heard over the air relative to the detriments and distortion resulting from use of this type of device stems, I believe, from incorrect adjustment. The chief mistake is trying to get too much by cranking in all the available compression or clipping, resulting in bassiness and degradation of speech quality. So better to start off by using too little rather than too much.

The following procedure is suggested when first setting up the processor with your mike and transmitter.

Set the processor controls as follows:

Input Gain—Max. clockwise.

Compression—Min. (fully counterclockwise)

Clipping—Max. clockwise.

Speaking into the mike with normal voice level, adjust the transmitter mike gain for normal modulation peaks. If the optional output attenuator is incorporated, then the transmitter mike gain should be left at its normal setting and the output attenuator adjusted for normal modulation. Having established the transmitter input by one of these methods, slowly rotate the clipping control counterclockwise while continuing to talk into the mike, and observe the output peaks. For a part of this rotation no change in peak swings will be noted, but a point will be reached where peaks begin to drop. This is the clipping threshold. Reset the clipping control slightly above the threshold point. Finally, advance the compression control noting that, while maximum peak swings do not increase, modulation troughs become shallower until the needle of the output indicator will "hang" within 80% of maximum. Optimum setting of the compression control will have to be determined with some experimentation, and may be varied for different conditions. As used by the author, the control is set between 12 and 3 o'clock dependent upon conditions. For local contacts the compression control may be set at minimum, leaving only the light clipping to prevent overmodulation.

Always remember that the processor is supposed to boost the weaker voice sounds and adjust for variations in speaking level, or distance from the mike. If you get reports of boominess or room noise you're overcompressing.

After you get it satisfactorily set up, you might want to increase the clipping control a bit more, but not so that obvious raspiness occurs.

Results

And now to the prime question, "What will it do for me?" No, it won't substitute for a linear or a beam, but properly adjusted it will give added punch and intelligibility that can make the difference between being poor copy or Q5 when the going gets rough. Needless to say, it adds nothing when your signal is 20 over S9.

In support of this claim I can say that the processor has been used on the air for several months, and has been subjected to many tests with other stations.

Used in conjunction with a Galaxy V Mark 2 transceiver and a Shure 444 microphone, each test has consisted of several transmissions with the processor in and out of circuit, with identical peak output being maintained on a monitorscope.

While it is obvious that no form of premodulation processing is going to increase peak output, many stations have reported an *apparent* increase of 1 to 2 S points when the processor is cut in. This is obviously caused by the AGC time constants in the receivers responding to the higher *average* signal, and has been most noticeable with receivers using audio derived AGC.

In all cases, stations worked have reported a significantly louder signal with processor in circuit. Under S2 signal conditions, 50% copy was reported without the processor, and 100% copy with it.

A Two Buck Signal Generator

Modulated FM yet.

The circuit in Fig. 1 is as simple a modulated transmitter as can be built. It has been useful in testing two meter FM receivers, alignment, (rf/i-f peaking) and as a short range transmitter. When used as an FM transmitter or wireless mike the range without an antenna is 100 yards plus and the audio is excellent. The components may be wired on a terminal strip or soldered to a small (2 x 2 in.) piece of copper clad board and then installed in a small minibox with the end cut out. The box will eliminate frequency shift due to hand capacitance and the open end will allow the signal to radiate directly from the tank circuit. If you must go first class, a one turn link coupled to the tank coil, one end to ground through a 5–20 pF capacitor and the other end to a pin jack will allow you to have a completely enclosed box with a plug-in whip antenna.

Construction

All leads should be kept to a minimum, and with short leads be sure to heat-sink the transistor and varactor leads when soldering. The varactor is from Poly Paks, 25¢ available in packs of four. The transistor is a Motorola MPS6512. The mike is an 89¢ lapel mike (crystal). If only an rf signal is needed for alignment purposes the mike, varactor, and 2 pF coupling capacitor may be eliminated. The coil for 147 MHz is two turns No. 16 wire ½ in. diameter and ½ in. long. A ½ x ½ in. hairpin loop will put you in the 432 MHz range. If modulation is used do not exceed the 2 pF value for coupling to the varactor.

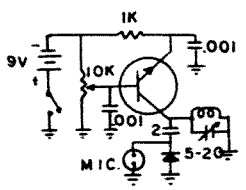

Fig. 1.

Three or four turns of hook-up wire as a gimmick capacitor works nicely. In the interest of slower tuning you may wish to parallel the tank capacitor with a small piston trimmer and use the 5–20 pF as a band set. An alternate method would be to mount the coil on a brass, slug-tuned coil form and tune with the coil slug.

Based on letters from past articles, parts appear to be a problem in some areas. I have a quantity of MPS6512 available for 90 days after this issue at 25¢ each plus an SASE.

transmitters THEN and *NOW*

I can remember, way back in the dim dark past, when I was a Novice, seeing an article by W1DBM in which he showed how an old carbon filament light bulb could generate sufficient rf to cause a troublesome level of TVI. Thinking back on that today, I can't but imagine the stir it might have caused back in the time this type of bulb was in style. Amateur transmitters in that time were weird and exciting, as well as noisy. A kilowatt rig made so much noise it had to be muffled in a special box.

Most of us like to believe that Marconi "invented" radio waves. Frankly, he didn't. He didn't even discover them. As one old-timer put it, nobody really invented these things. They were there all the time waiting to be discovered. That was the case with radio waves. Long before Marconi's parents even so much as held hands and Hertz was still toddling around in short pants, another man was hitting awfully close to the right idea.

His name was James Clark Maxwell. Born in Scotland, he was as a boy so fanatically interested in science that his schoolmates nicknamed him "Dafty." When he was barely in his teens, though, he was turning out scientific writings that made the experts sit up and take notice. As a man of forty, he had the distinction of being appointed to a professorship at Cambridge, England.

In 1873 "Dafty" came up with the startling theory that electricity and light were similar in nature, and that they were waves. Now, a wave is defined as a vibration of a substance. Sound, for instance, is the vibration of air. Maxwell had to define the substance through which light traveled.

He called the medium ether. The word ether had long been used to describe the substance of which space is composed. Maxwell accepted this theory, and offered

the theory that light waves were merely ripples in the ether. Now all he had to do was produce these ripples artificially. Only death could stop him, and it did.

Heinrich Hertz had grown to manhood by then, and was lecturing in the University of Kiel. He was intensely interested in Maxwell's theory, and there were many entries in his diary; "Thought about electromagnetic rays. . .Hard at Maxwellian electromagnetics. . .Nothing but electromagnetics." In the Kiel high school library, there were two coils of wire, each with a spark gap across it. One day, as he discharged a Leyden jar through one coil, he had a spark jump the gap in the other coil. Hertz experimented with this phenomenon for eight years. Using homemade equipment and working in the school lab after classes were over, he managed to transmit impulses over a distance of about forty feet. Small as this distance may seem, it was enough to enable Hertz to verify many of Maxwell's theories. Building huge curved mirrors and prisms, he demonstrated that the electric waves could be reflected and refracted the same as light waves. By the time he died in January, 1894, the world had a sound knowledge with which to start the development of wireless. Hertz himself had no idea of what he had started. When asked whether or not his waves would ever be used for telegraphy or telephony, he said he didn't think it would ever be practical.

Hertz's transmitter was very simple —merely a spark gap in a large loop. When another loop of the same size was nearby, a corresponding spark would jump in the receiver loop. Before it could become practical, a more sensitive receiver and a better means of producing the waves had to be developed. When Branley's coherer was developed the world was ready for Marconi.

Marconi began experimenting with Hertzian waves around 1895. He used a very similar transmitting apparatus, except that he added an antenna and ground. Much of Marconi's success, however, should be credited to Branley's coherer. It was the start of the age-old problem, "You can't work 'em if you can't hear 'em." By the spring of 1897, he had filed a patent for "signaling through space without wires." In July, 1897, the Marconi Wireless Telegraph and Signal Co. was formed, and the radio industry was on its way. Lloyds of London asked Marconi to install equipment in two lighthouses on the North Irish coast and instruct the keepers in its operation; thus the first practical use of wireless was launched.

One of Marconi's big problems was separating signals one from the other – that is, the problem of tuning. That meant that the receiver should be able to accept signals from one transmitter and reject all others—a simple enough accomplishment today, but in that day, resonance was unknown. Marconi called the condition "Syntony." With the help of Sir Oliver Lodge, who, by the way, had helped Marconi before in the development of the coherer, syntony was achieved and patented by 1900.

One of Marconi's helpers, Ambrose Fleming, had developed a receiver using a "valve." This first vacuum tube relied on a phenomenon which Edison had noticed some years before, but not patented. Fleming scooped Edison on the patent of this device, but Edison had his revenge. He had a prior patent on the aerial and Marconi had to pay for rights.

For the first couple of decades, most of the development in radio techniques was confined to receivers. Transmitters remained basically quite simple—a spark gap connected to an antenna. In Marconi's first rig, he used a transformer similar to the ignition coil of an old Model T Ford. The primary power was supplied by batteries through an interruptor similar in principle to an electric buzzer. Zinc was preferred for the electrodes, although brass or copper could also be used. One electrode was grounded, and the other connected to an antenna through a series inductance. The inductance was slide-tuned. That's all there was to it. This circuit was still around in 1920, although an old book says, "The government authorities are not inclined to grant a license to operate the transmitter in Fig. 12, unless it be of a low power and located in a region where it is not apt to interfere with the working of government or commercial stations." This was in 1920.

An improved version used an ac generator

and coupled the antenna inductively to the transmitter. The coils were still slide-tuned, although a capacitor was sometimes inserted in series to correct the aerial "if its natural wavelength exceeds 200 meters."

Most of the spark transmitters utilized an ac spark. The resulting rf was therefore modulated at the ac frequency. This made it possible to hear the signals with a crystal receiver, when they would otherwise have been inaudible. The hissing crash of the spark could be heard far from the operator's shack. The spark itself occurred between the ends of two metal bars about 1/16 to 1/8 inch apart. The bars were equipped with fins to facilitate cooling. The hot ends were generally flat, although pointed ends would spark more easily. Flat ends would quench better between cycles of the generator, giving better modulation. The generator frequency was preferred to be around 200 to 400 Hz, since operators preferred a nice musical note. As the art developed, ways were found to better govern the frequency of the spark.

One way was the rotary gap. In a rotary gap, a conductor was spun between a number of points, making and breaking the gap at a pleasant-to-hear frequency. There were two types of rotary gap, namely synchronous and nonsynchronous.

The difference was simply that the rotating member was, in one instance, mounted directly on the generator shaft, so that its spark always occurred at the peak of the generator's cycle. Of course, this required the generator to have an output frequency the same as the modulation frequency. In the cheaper nonsynchronous spark, the tone heard at the receiving end would be a composite of the gap frequency superimposed on the generator frequency. This gave a rougher note to the receiver.

Quite surprisingly, the principle of an LC resonant circuit was applied first to the step-up transformer between the generator and the gap, rather than in the rf portion. In fact, the early books seldom even show an LC resonant circuit in a transmitter until vacuum tubes entered the picture. They were, of course, used in receivers almost from the beginning.

One other form of the spark gap was the multiplace, or "quenched" gap. This consisted of a number of copper disks, separated by insulating washers, mounted between the electrodes. While this was a more efficient rf generator, it lacked the musical sound of the rotary gaps. However, if the power supply was at a high enough frequency, it was quite satisfactory.

Finally, it is worth mentioning that every radio shack had a "test buzzer." This was a common electric buzzer, sometimes equipped with a tuned circuit, which could be connected to an antenna. Its function was the same as signal generators in today's radio-TV repair shop. The buzzers were quite efficient. One account states that, when connected to an antenna, they could be picked up several miles away.

Most of the tuning of these early transmitters was done inductively. In the earliest models, the main frequency-determining element was the antenna, together with an inductance at the transmitter end. One interesting sidelight is the use of the centimeter as a unit of inductance. One centimeter equaled 0.001 μH. Eventually, as the state of the art improved, and the nature of radio signals was better understood, capacitors began to be used. They were first used in receivers, though, and for good reason. The voltage required to produce a good reliable spark ran well up into five figures, and even today you can seldom find a capacitor that will withstand that kind of voltage.

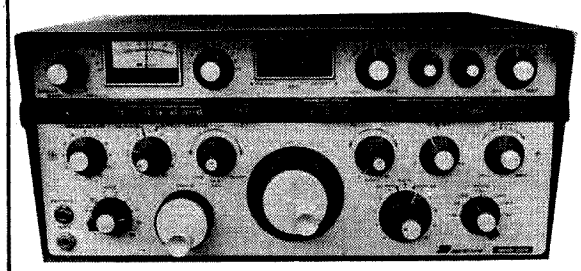
Around 1903, a Danish engineer by the name of Valdemar Poulsen tackled one of the hairiest problems in this fast-growing art. Spark transmitters, you will remember, were powered either by an interrupted direct current or by alternating current. With each pulse of the direct current, or with each half cycle of the alternating current the rf would appear as a series of damped waves. While this served to make the signal audible, it nonetheless wasted a lot of power and rapidly lost its readability as the distance increased.

Poulsen's approach to the problem was to devise a gas-enclosed dc arc. Now, here one should realize that there is a difference

between an arc and a spark. A spark is a sudden, discontinuous discharge, while an arc is a sustained discharge. An arc needs a high dc voltage to start it, and can then be sustained by a comparatively lower voltage, while a spark is constantly making and breaking at the supply frequency. The Poulsen arc, then, used direct current, and operated at a slightly lower voltage than the spark transmitters. Being a dc arc, it could not be keyed on and off, because it could not be broken and restruck fast enough. Poulsen answered this by having the key short a portion of the tuning coil, introducing frequency-shift keying. The Poulsen arc produced a nearly continuous wave. With no modulation on the signal, it couldn't be heard with the conventional receivers of that time. This bug was, strangely enough, tackled at the receiver end. A device called a "ticker" opened and closed the circuit to the earphone several times a second so that the dc level resulting from rectification of an unmodulated signal was broken to produce a buzzing sound. Then a man by the name of Reginald Fessenden came onto the scene.

Fessenden began with what was intended to be an improvement to receivers, and ended up revolutionizing the entire field of radio communication. His first idea was to make an undamped radio signal, as a pure continuous wave was called, audible by injecting another signal into the receiver at a frequency a few hundred cycles removed from the incoming signal, thereby producing an audible sound. He called it the "heterodyne." Utilizing the same principle, he then tried injecting the audio signal at the transmitter end. From here the next step was obvious—to inject the human voice in the same way.

In 1900, just five years after Marconi had sent his first CW message, Fessenden succeeded in transmitting the human voice between two fifty foot antennas a mile apart. Ever try to modulate a spark? Probably not, but if you imagine the problems that could you can get some idea of what Fessenden was up against. True, he did transmit a voice, but the buzz on the signal nearly overwhelmed it. Even with a Poulsen arc there was just too much noise on the signal. If Fessenden was to succeed, he needed a device that would produce radio signals which were perfectly clean, so far as noise is concerned, and at a high enough frequency. He had set his sights on 100 kHz.



Fessenden had to wait until 1906 before he could progress any further. Until then, there just wasn't any such thing as a generator of pure rf signals. But in 1906 Dr. Ernst Alexanderson, working for General Electric, developed an alternating current generator with a very high speed rotor and a great many pole pieces. It put out a frequency of 50 kHz. Fessenden had wanted twice that number, but he had been disappointed so many times he was ready to try anything. By December of 1906 he felt it was ready for a demonstration.

The demonstration itself took place on Christmas Eve. Fessenden had passed the word around beforehand through scientific circles, and a few curious but skeptical witnesses gathered in his shack. He began in a fairly innocent manner by sending out a CQ in code. Listeners on land and at sea waited for the code signals they expected to follow. They received an unprecendented jolt. Fessenden picked up the mike and identified himself. Then a gramophone record of Handel's Largo was started up, with the horn pointing into the microphone (The world's first D.J.) After the record was over, Fessenden played a violin solo, and sang, "O Holy Night."

Fessenden himself said he wasn't much of a singer, but no singer before him ever created such a stir. Our generation was deeply inspired on Christmas Eve 1968 by hearing an astronaut read the Bible from the moon, but it was nothing compared to the thrill experienced by the many amateurs and ship's radio operators as they heard this hymn coming out of the ether, which heretofore had carried the harsh raucous buzz of morse code, at this very nostalgic and sacred time of the year. Formality and protocol went down the drain as many a ship's sparks shouted to the captain to come and hear this miraculous voice. One operator, probably a little lonesome for home, entered into the log that he had heard

the Incomparable

by CX7A signal/one

Features:

- RELIABILITY IS NOW standard equipment. Every CX7A "burnt-in" and cycled more than 96 hours.
- QUALITY-PLUS. Every component is instrument grade. American-made, and individually tested.
- ALL MODES 10 thru 160 meters in full 1 MHZ bands with overlaps.
- BROAD-BAND TUNING. Instant band changes without tuning.
- TRUE BREAK-IN CW with T/R switching.
- IF SHIFT – deluxe QRM slicer.
- PRE-IF NOISE-BLANKER that really works.
- RF ENVELOPE CLIPPING – sounds like a Kw.
- TWO VFO'S Transceiver Plus receiver.
- BUILT-IN: Spotter, FSK shift, transmit offset, wattmeter, SWR meter, electronic CW Keyer.

Specifications:

- SENSITIVITY: Better than 10db signal-plus-noise-to-ratio for .25 microvolts at 28 MHZ.
- SELECTIVITY: 2.4 KHZ @–6db, 1.8:1 (6:60db) shape factor. (16 pole crystal lattice Filters) optional:
- CW-300 and 400 HZ. FSK-1200 HZ.
- CARRIER and unwanted sideband suppression. Minimum 60db.
- IMAGE and IF REJECTION: more than 60db.
- POWER LEVEL: 300 to 500 watts p.e.p. plus, continuous duty cycle.
- POWER AMPLIFIER: 8072 final completely broad-banded driver and final. 150 watts continuous dissipation rating.

It's Perfection for $2195

If you want to move up to the BEST, give Don Payne, K4ID, a call for personalized service, a brochure, and a KING-SIZE trade-in on any gear you have - one piece - or the whole station.

Six days (615) 384-5573

Nites Sundays (615) 384-5643

an angel singing in the ether on Christmas Eve.

The broadcast was a howling success. Letters started pouring in from listeners hundreds of miles away. The learned scientist repeated his broadcast again on New Year's day. So the ice at last had been broken. But there were still many obstacles to overcome. For one thing, there was only so much available frequency spectrum. Fessenden's Alexanderson alternator couldn't go over 50 or so kHz. Before voice transmission could become practical, higher frequencies had to be achieved with a pure continuous wave, and there just wasn't any generator capable of doing it. The world was ready for Lee DeForest.

When Edison stumbled upon thermionic emission in 1893, he simply jotted it down in his notebook and forgot it. His young assistant, Ambrose Fleming, didn't, however and upon discovering its effectiveness in detecting radio signals, patented it in his own name. Fleming was, at the time, working for Marconi, and would not license his valve in this country. American ingenuity was faced with a real challenge. At first the challenge was met by several types of crystal detectors, but then DeForest invented the vacuum tube.

All DeForest knew was that he had produced a better detector. But in 1910, Edwin H. Armstrong, while experimenting with DeForest's "audion," inadvertently completed a feedback loop in the proper phase, and noticed a whistling sound in the earphones as he tuned over a station. Could it be possible that the audion was generating radio signals? It was. Armstrong had discovered it, but somehow DeForest got the patent.

In this sort of thing, however, patents don't mean that much. It is better to say that new circuits were discovered rather than invented. As fast as an experimenter could come up with a new configuration, he would take out a patent. Hartly, Colpitts, it goes on and on. The only really new thing was crystal control of frequency, discovered by Pierce around 1917. Except for that, progress has just been a refinement of what we already had.

PRACTICAL AMATEUR FM REPEATERS

Amateur FM repeater activity in the United States is growing with leaps and bounds. Most major metropolitan centers now have repeaters operating on 6, 2, and 3/4 meter bands. The most popular frequencies are 146.34 MHz input and 146.94 MHz output or 146.16 MHz input and 146.76 MHz output. Other repeaters operate on the six and 432 MHz bands. Most of these repeaters are maintained by a small, dedicated group of amateurs who act in behalf of a larger group who use the repeater. In other areas there are groups who are interested in establishing a repeater but do not have sufficient information upon which to base their efforts. This is an attempt to fill this void.

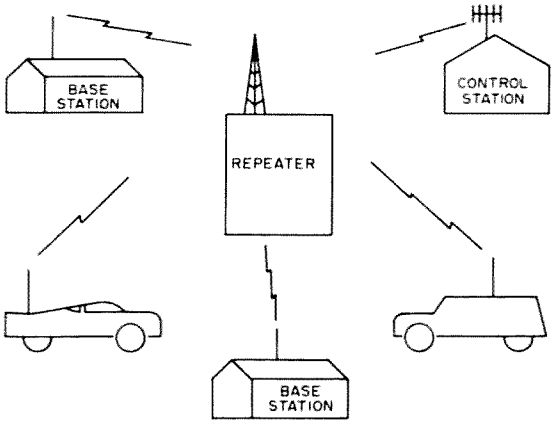

Fig. 1. Repeater operation.

Since each locale will have its own preference as to bands, locations, and available equipment I will deal in broad terms where possible. Specific mentions of equipment will refer only to equipment manufactured by Motorola Communications and Electronics, Inc. This specialization as to references is for two reasons: I am more familiar with Motorola equipment than any other brand; and, because Motorola is now releasing large quantities of equipment to the amateur market in certain areas.[1]

Types of Repeaters

The types of repeaters may be divided and subdivided into several areas: The first division is whether the repeater is an open or closed system. In an open system any carrier on the proper input frequency will key the repeater. This allows access by any amateur to the repeater. In a closed system some type of actuating signal is required to

1. Motorola is releasing to amateurs from the Atlanta, Georgia, Dallas, Texas, offices directly, and in Chicago, Illinois through a subcontractor. Conditions of sale require a photographic copy of the amateur license, a signed statement that the equipment will be used exclusively for amateur operation and not resold for commercial use. Also, only two units of a particular model will be sold to any one individual. Serial numbers are recorded so that if any equipment is returned to commercial service the offending amateur will be known.

operate the repeater when a signal is transmitted on the proper input frequency. This signal usually consists of either a single tone[2] sent at the beginning of each transmission or a low frequency continuous tone transmitted with the input signal (e.g. Motorola's "Private Line" or General Electric's "Channel Guard" systems). In the single tone system a tone decoder actuates a relay which then allows the repeater receiver to operate normally until the signal stops. At this time the system resets and a short single tone is again needed to actuate the system. In the continuous time system a low frequency tone (usually below 200 Hz) is continuously transmitted with the input signal. This tone is decoded by a reed resonant system and the repeater receiver then operates. The former system (single tone) does not require resonant reeds (L-C or R-C networks will suffice) whereas the latter system requires reeds both in the transmitter and receiver which have tolerances of less than 0.5% or better. Since these reeds are comparatively expensive, most amateur closed repeater systems use the single tone system.

Once the decision has been made to operate either a open or closed repeater, the second subdivision of types comes into play. Is the repeater to be of the on-site or of the split-site variety? The on-site system requires that the input receiver and the output transmitter be at the same location. In the split-site system the input receiver is located at some distant point and connected to the output transmitter by either a radio link or a wire line. Each system has its good points.

The split-site system is best when the input and output frequencies are to be close spaced (e.g. 100 Hz low band-6 Meter systems) or when a high power transmitter such as a 250 watt output unit is to be used. The major drawback to this system is that some type of control link must be maintained between the transmitter and receiver sites. This may be either a wire line leased from the telephone company or a radio link on 220 MHz or 440 MHz. The wire lines are expensive, and the radio links must each have a seperate radio control system to comply with FCC regulations. Also, because the transmitter and receiver sites will not have the same geography the radiation patterns will be different. This sometimes results in transmitter "dead spots" where the receiver is hearing and receiver "dead spots" in locations where the repeater transmitter is strong.

The on-site repeater systems place the equipment at one central spot for easier servicing. This is of great help when the system needs repair. When all equipment is at one spot only one team is required to service, maintain, or repair the equipment. Since the location is the same, the antenna radiation patterns will be similar when the same type of antenna is used for both transmitting and receiving. In fact, in sophisticated systems a hybrid-ring type of antenna coupler may be used to allow simultaneous receiving and transmitting on the same transmitting antenna. The drawbacks are that extensive shielding must be used on both the transmitter and receiver (details on this will be covered later) and that tuned cavities must be used in the receiver and transmitter antenna leads (more on cavities later). Also, the noise induced into the receiver will have a degrading effect [2]. This noise is partially overcome by the cavities, but some still remains.

No matter which type of system is chosen, the transmitting power and receiver sensitivity should be balanced so that a properly operating mobile station will be able to talk into the system about as far as it can be heard. This can usually be accomplished by varying the transmitter power level. The perfect system would allow talk-back and hear ranges to be exactly equal. Since this is impossible to achieve, it is then desirable to set the transmitter power a little higher than needed to cover "dead spots" within the normal range of the system.

Choosing the Equipment

The equipment chosen to be used at the repeater site(s) depends upon several things:

2. Wolf, S.M., *FM Schematic Digest*, Two-Way Radio Engineers, Inc., Boston, Mass., pp 91–92.

3. Murphy, J.A., "Receiving System Degradation in FM Repeaters," *Ham Radio*, May 1969, pp. 36–39.

The band to be used, power level required, physical characteristics of the site, type of control link, etc. Of course in different areas different types of equipment will be available. Whenever possible, choose the newest model which will do the job. This is a matter of common sense, for the older a piece of equipment the more chance for failure. It is often desirable to choose a transmitter with power handling capabilities greater than the system requires. For example, if the system design calls for a 30 watt output transmitter, chose a 50 or 60 watt output unit. This allows the unit to be operated far below the maximum ratings, thus allowing greater tube life and increasing the reliability of the system. If the site is enclosed (building, etc.) a weatherproof enclosure is not needed. A standard rack cabinet, mobile housing, etc. may be satisfactory. If the site is exposed, a weatherproof cabinet or rack must be employed. Most of the major manufacturers of FM equipment use such housings and they are available at reasonable cost on the used market. If possible, choose a site with an existing structure to support the antenna. The site may be a tall building, radio or TV transmitting tower, amateur tower, etc. Only if absolutely necessary should a tower be installed for the repeater. Satisfactory towers are expensive, hard to install, and must be adequately maintained.

FCC regulations require some type of control on each transmitting site. This includes link transmitters in the case of split site repeaters. This control may be maintained by either wire or radio above 220 MHz. Because of this, it is necessary to include equipment for maintining complete control capabilities.

A list of equipment absolutely needed at the repeater site(s) follows:

1. Receiver for input frequency
2. Transmitter for output frequency
3. Antennas for above
4. Receiving cavity (especially at on-site locations)
5. Transmitting cavity
6. AC Power Supplies for all equipment
7. Suitable housing for all equipment
8. Control equipment including:
   A. Tone actuated relays
   B. Wire line coupling equipment or
   C. Radio receiver for control link
9. Squelch relays for each receiver (COR)
10. Timer which may be adjusted for 3 minutes or less
11. ID system either voice or MCW
12. Link transmitter for split-site systems
13. AC power line to handle the load
14. Miscellaneous cables power and rf

Desirable maintainence equipment is as follows:

1. Signal generator with attenuator calibrated in microvolts
2. Wattmeter with known accuracy at the desired frequency
3. Frequency standards[4]
4. Deviation measuring equipment[5]
5. Test set or metering panel if Motorola equipment[6]
6. Complete set of spare transmitter and receiver strips
7. Extra set of crystals
8. VOM or VTVM
9. Small tools
10. Dummy load (usually 50Ω)

Setting Up the Repeater

Once the equipment has been chosen, the next step is to set up the repeater in a convenient location (garage?) for assembly and initial checkout. Each piece of equipment should be individually checked out, retuned for the repeater frequency, and then given an extended "shakedown" run. If the repeater is to be of the on-site type it will be necessary to completely shield the transmitter and receiver strips. Again the major manufacturers can provide a shielding kit for this purpose. However, the same can usually be made at a lower cost by the amateur group. Such a shielding kit normally consists of a "cane" metal enclosure which completely surrounds each unit. All power leads must be bypassed by the use of series chokes and disc capacitors. In cases where the power is brought into the unit through a single power plug an adaptor may be made that goes from the shielding to the chassis

4. Such as TS323, Gertsh FM3, Lampkin 105, etc.
5. Zook, G.E., 'Now You Too Can Have A Deviation Meter," 73, August 1969, pp 96–97.
6. Zook, G.E., 'Add-On FM Test Set," 73, December 1968, pp 18–19.

plug and which includes the needed bypass circuitry.[7]

If the repeater is to be of the on-site variety, cavities will probably be needed for both the receiver and transmitter. These cavities may be bought, scrounged, or constructed.[8] The purpose of these cavities is to isolate the receiver from the transmitter and thus reduce the degrading of receiver sensitivity. In split-site systems cavities may be desirable to reduce interference from other services located at or near the site.

AC power supplies are an obvious necessity. Many supplies built by Motorola, RCA, GE, and others will operate one or more receivers as well as the transmitter. These supplies are highly reliable. However, many older units use tube type rectifiers for the transmitter high voltage. These may be substituted by silicon diode arrays which give better reliability and cooler operation. If commercial supplies are not available, then construct the supplies using the best transformers, capacitors, and solid state circuitry available. The Motorola P8434 (30 watt output transmitters) and P8464 (60 watt transmitters) power supplies are good examples of the commercial units available.

Suitable housings depend, as mentioned before, on the physical characteristics of the site. If the unit is to be housed inside of a building, such as the elevator room of an apartment building, a cabinet rack will provide sufficient room for the transmitter, receiver, control links, etc. If the repeater must be exposed, such as on a tower or building roof, a weatherproof housing must be used. Such housings are commonly used by the major manufacturers. Special housings for pole or tower mounting are also common and may be obtained if the application requires. If a housing must be built, use the best materials available. Remember that ventilation is required, but that ventilation holes must also be weatherproof.

Since FCC regulations require 24 hour control of any remote station it is necessary to provide a control system. This control system may be either by leased wire line or radio control above 220 MHz utilizing directional antennas. In the case of wire line, units are available from the manufacturers for such applications. However, wire lines are expensive. Thus, most amateur repeaters utilize a radio control link. With the "splitting" of the UHF business band (450-470 MHz) many units are becoming available. Of these the Motorola T44AAV (mobile) and L44AAB (base) units are the most common. Since the transmitter and receiver strips are identical in each unit, either may be used as the basis for control links. A scheme for using these units is outlined later in this article.

When radio links are used it is necessary to use some type of information to operate or disable the repeater. Although some repeater groups are now using digital techniques, the easiest method is tone control. Simple tone oscillators such as used in AFSK systems may be used with RTTY type tone decoders at the repeater site. These decoders may be used to operate a stepping relay to shut the repeater down, then back on, etc.

The squelch relay is needed to operate the transmitter when a signal is received by the input receiver. Such a circuit reproduced as Fig. 2. A detailed description of the operation of this circuit may be found on page 92 of the *FM Schematic Digest* published by Two Way Radio Engineers Inc., a *73* advertiser.

A timer is also required by the FCC. This insures that the repeater transmitter will not transmit for a period exceeding three minutes. This prevents tying up the frequency if someone inadvertantly keeps a transmitter operating continuously on the input frequency or if there is failure in any portion

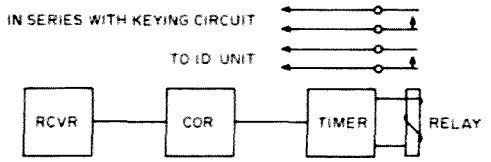

Fig. 3. Timer logic.

of the repeater system. Such a timer may be of either the electronic or electro-mechanical type. The electro-mechanical type is cheaper in most cases. The timer is actuated by the squelch relay whenever a signal is received. If the received signal stops before the time limit is up, the timer resets and begins operation anew when another signal is received. When the signal is in excess of the allotted time, the timer shuts down the repeater transmitter. When the signal stops, the timer resets, and the repeater transmitter may again operate. A working hookup for the timer appears as Fig. 3.

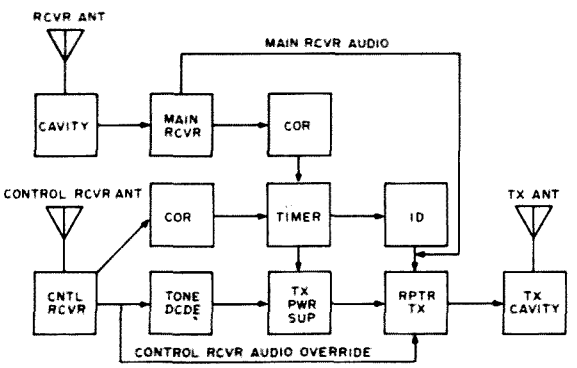

Fig. 4. On-site repeater operation.

Each repeater licensed by the FCC also must have its own call sign. This call sign must be transmitted in accordance with FCC regulations. Two methods are suitable for repeater ID: Voice ID and MCW ID. The voice ID may be accomplished by using a closed loop on a tape recorder playback head. The actual words used can vary, but many repeaters have the call sign and location. The MCW method can use either an electromechanical arrangemen such as a code wheel or an electronic method[9]. In either case the ID is usually as follows: "QRA DE WA5XXX."

9. Connors, John, "A Programmable Repeater Identifier," *Ham Radio*, April 1969, pp 18–23.

The repeater System

The repeater system components and their relationship to each other are described in Figs. 4 and 5. Fig. 4 is the on-site repeater diagram and Fig. 5 is the split-site repeater diagram.

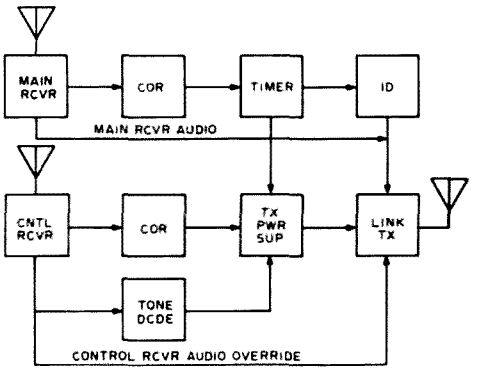

Fig. 5A. Split-site receiver.

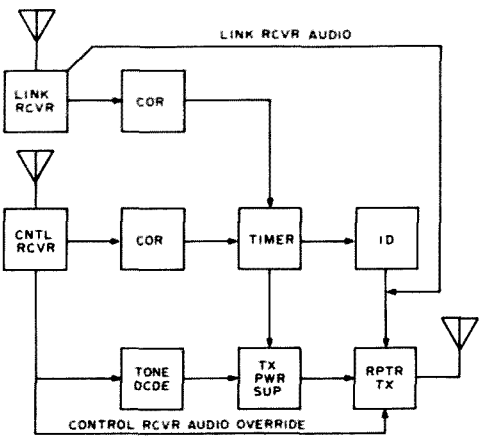

Fig. 5B. Split-site transmitter.

Control Stations

The block diagram of a control station appears as Fig. 6. This station (or a number of these stations) must be manned 24 hours per day if the repeater is in constant readiness. If the control station is not manned for any length of time, FCC rules

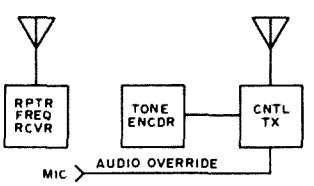

Fig. 6. Control station.

require that the repeater be made inoperative until the control station is remanned. Such a control station should consist of a transmitter capable of operating on the control link frequency, a tone encoder for operation of the control circuitry, a directional antenna[10] (also required by law), and a receiver capable of receiving the repeater transmitter. The logic at the repeater site should be wired to allow the control transmitter to override any incoming signal (see Fig. 7).

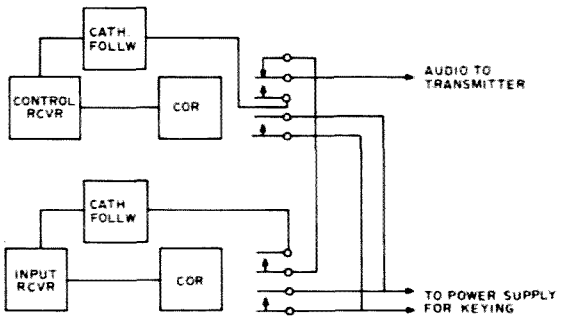

Fig. 7. Relay logic for audio override.

Logging Station

The FCC also requires that accurate logs of the repeater operation be kept. A simple method of achieving this is to use a receiver on the repeater transmitter output frequency with a COR operating a tape recorder. If a dual channel recorder and a second receiver tuned to WWV or CHU are used, a time hack will appear along with the information transmitted through the repeater. The tape can be changed and retained for one year and then reused. A block diagram of this appears as Fig. 8.

Antennas

The antennas used in the repeater system should be omnidirectional. Everyone has his own ideas as to what type is best, so I will not try to recommend any one particular type. If the on-site system is used, keep the receiving antenna as far away from the transmitting antenna as possible. This will reduce the receiver desensing by the transmitter. The radio link and control link antenna(s) should be directional. Small beams[11] or modified UHF TV corner reflector make excellent link antennas (especially when fed with low-loss foam twin lead).

Audio Coupling

Commercial FM repeater systmes often use a wire line termination chassis for coupling the audio from the input receiver to the output transmitter. This system is fine if the chassis is available. Since this is not usually the case, a simpler and less expensive method must be used. The simplest and most effective method is to connect a cathode follower circuit to the audio output of the discriminator. The output of the cathode follower is then fed into the microphone input of the repeater transmitter (or link transmitter in the case of split-site repeaters). This system allows the deviation of the output transmitter to be independently controlled by the deviation control in the transmitter, and not by the audio gain control in the receiver. This way the audio section of the receiver may be used for monitoring whenever a maintenance team is at the repeater site. If the audio is taken from the receiver audio output stages and then coupled to the transmitter, any resetting of the audio gain control will require recalibration of the transmitter deviation. Usually the audio required for sufficient deviation results in a very low audio output from the receiver. Thus, when a service team turns up the audio to hear incoming signals, the deviation from the transmitter increases. Thus, it is desirable to isolate the audio going into the transmitter from the audio going to the speaker. This is why the cathode follower circuit. See Fig. 9 for a working unit.

Audio Override Circuitry

It is very desirable to allow the control station audio override. This enables the

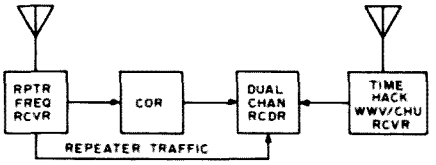

Fig. 8. Block diagram.

10. Zook, G.E., "Curtain Rods, Coat Hangers, and Control Links," 73, June 1969.
11. Ibid

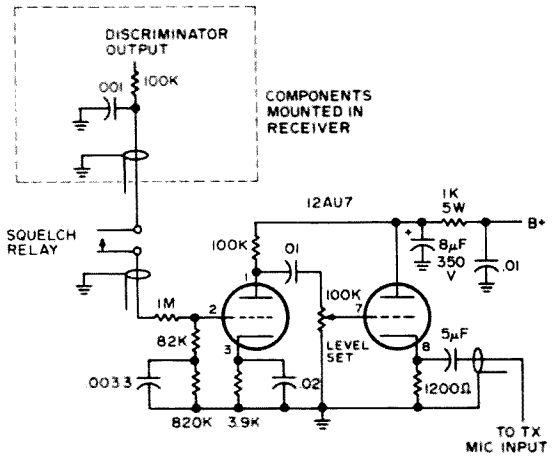

Fig. 9. Cathode follower.

control station to break in over any station on the regular input frequency. This may be accomplished with simple relay logic which appears as Fig. 7.

Tone Control Units

A tone control unit for turning the repeater off and on is a legal necessity. The basic circuit can be the same as a RTTY tuning unit. The only difference is that the tone is continuous rather than shifting. To avoid unauthorized control, the control tone may consist actually of two tones. The only requirement is that they not be harmonics of each other or have a beat note that is a harmonic or sub harmonic of either tone. The relay logic may then be worked so that both tones must be present for the control system to work. A diagram of the logic appears as Fig. 10.

Single Tone Units for Restricted (or Closed) Systems

Single tone units for closed systems are only slightly harder to build than normal audio circuits. The requirements are that the tone be short and on the correct frequency. The schematic of the tube type Motorola encoder (transmitter unit) and decoder (r-eceiver unit) appear as Fig. 11 and 12. These circuits may be easily duplicated and the

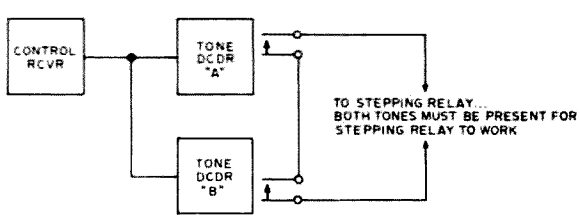

Fig. 10. Relay logic for two tone control.

Single Tone Units for Restricted (or Closed) Systems

Single tone units for closed systems are only slightly harder to build than normal audio circuits. The requirements are that the tone be short and on the correct frequency. The schematic of the tube type Motorola encoder (transmitter unit) and decoder (receiver unit) appear as Fig. 11 and 12. These circuits may be easily duplicated and the tone frequencies varied to fit local requirements.

Deviation

Although amateur FM activity has been generally of the wideband (±15 kHz) variety the trend is toward narrowband (±5 kHz). This is because of two things: The equipment now being released is of the narrowband variety and the population on the VHF bands is increasing by leaps and bounds thus requiring more and more channels. Wideband receivers will receive narrowband signals with a loss in audio gain. This may be overcome by the addition of audio recovery circuitry. Such circuitry usually consists of only two or three resistors. The other narrowbanding circuitry consists of sharper high and low i-f stages. These are not normally required in amateur operation. When a narrowband receiver is used in a

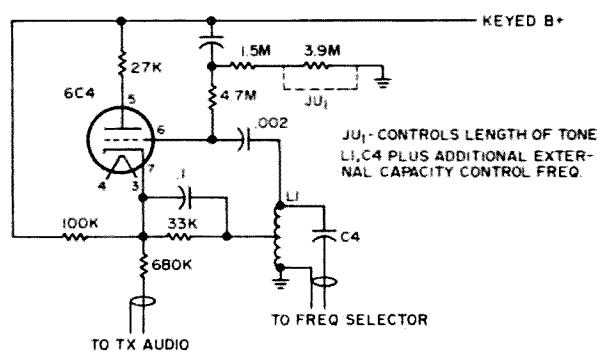

Fig. 11. Motorola single tone encoder.

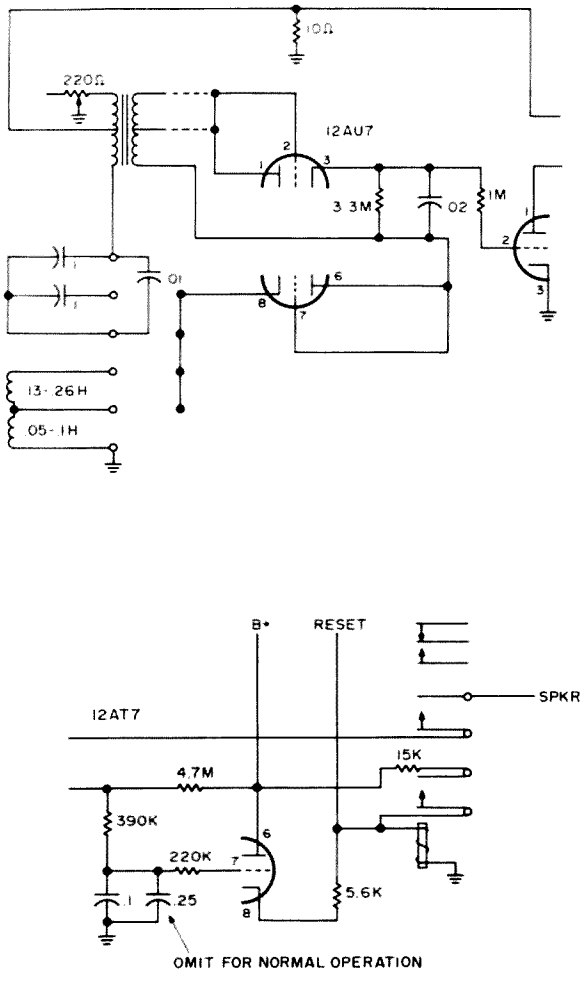

Fig. 12. Motorola single tone decoder. See p.f 91–92 in FM Schematics Digest for frequency and operation information.

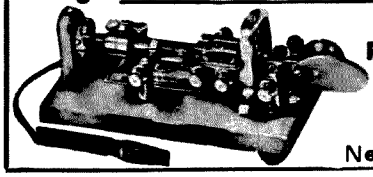
wideband system, the signals will "chop out" unless the squelch is turned off. If the units in a particular area are divided between narrow and wideband units it is possible to use ±7.5 kHz deviation. This is sometimes called "belly-band." Such deviation will not chop out on narrowband receivers and will produce sufficient audio on wideband receivers.

The repeater system should be adjusted so that whatever deviation comes into the system goes out at the same level up to the point at which the transmitter clipping circuit takes over. This requires a little patience in adjustment, but it is necessary especially when the units using the repeater also work direct on other frequencies.



Location

The location(s) for the repeater must be carefully chosen. Just because a location is

Box 1201 B Champaign, Ill. 61820

high it may not be the most desired. Often high buildings are built in lower areas. Radio and television transmitting towers are often built on the highest points around but may be located some distance from the desired coverage of the repeater. Also, the noise level at some sites may be much higher than at others. Close proximity of heavy traffic may affect six meter receivers but have much less effect on two meter equipmen. Other transmitters in the business or public safety services may cause intermod which may be greater at one location than at others. Thus, it becomes necessary to check the site out before the repeater is installed. This checkout should be made in several trips to the site at different times of the day and on different days of the week. The noise level on Sunday afternoon will probably be much lower than on a Monday afternoon when everything is in full swing. At night, neon signs and similar electrostatic systems may produce interference which adds to the total noise figure.

The desired location should have the following characteristics: high in relation to the area to be covered; centrally located within the desired area; convenient for access to the equipment for service; have an enclosed weatherproof place for the equipment; have sufficient power capabilities; low or no charge for use. Of course not all criteria can be met in all cases. It may be necessary to sacrifice an enclosed mounting area for a lower noise level. Or, in the case of a centrally located TV transmitting tower ease in access may be sacrificed for the height gained. In all cases a little common sense will save many headaches. For instance, don't put a six meter repeater on a channel two tower! The lower sideband of the TV signal though attenuated will completely block the six meter receiver.

If a location is found that meets all criteria except permission for use, it is often only necessary to approach the local Civil Defense or Red Cross office. Often these organizations will lend their influence to obtain permission to use a site (often at no charge, even for electricity!).

The Perfect Repeater

There is really no such thing as a perfect

SELECTED
CONVERTERS AND RECEIVERS

40 dB GAIN 2.5–3.0 N.F. @ 150 MHz

2 RF stages with transient protected dual-gate MOSFETS give this converter the high gain and low noise you need for receiving very weak signals. The mixer stage is also a dual-gate MOSFET as it greatly reduces spurious mixing products – some by as much as 100 dB over that obtained with bipolar mixers. A bipolar oscillator using 3rd or 5th overtone plug-in crystals is followed by a harmonic bandpass filter, and where necessary an additional amplifier is used to assure the correct amount of drive to the mixer. Available in your choice of input frequencies from 5–350 MHz and with any output you choose within this range. The usable bandwidth is approx. 3% of the input frequency with a maximum of 4 MHz. Wider bandwidths are available on special order. Although any frequency combination is possible (including converting up) best results are obtained if you choose an output frequency not more than 1/3 or less than 1/20 of the input frequency. Enclosed in a 4-3/8" x 3" x 1-1/4" aluminum case with BNC receptacles, power and antenna transfer switch. Thousands of our converters are now in use by satisfied customers, many of whom are government agencies and universities.

Model 407 price: 5–200 MHz $42.95
201–350 MHz $44.95

Prices include .005% crystal. Additional crystals $5.95 ea.

UHF 20 dB MIN. GAIN 3 to 5 dB MAX. N.F.

This model is similar in appearance to our Model 407 but uses 2 low noise J-FETS in our specially designed RF stage which is tuned with high-Q miniature trimmers. The mixer is a special dual-gate MOSFET made by RCA to meet our requirements. The oscillator uses 5th overtone crystals to reduce spurious responses and make possible fewer multipliers in the oscillator chain which uses 1200 MHz bipolars for maximum efficiency. Available with your choice of input frequencies from 300–475 MHz and output frequencies from 14–220 MHz. Usable bandwidth is about 1% of the input frequency but can be easily retuned to cover more. This model is now in use in many sophisticated applications such as a component of a communications link for rocket launchings.

Model 408 price $51.95
.005% crystal included.

VHF FM RECEIVER
11 CHANNELS • 135–250 MHz

● 11 crystal-controlled channels. ● Available in your choice of frequencies from 135–250 MHz wide. ● I.F. bandwidth (channel selectivity) available in your choice of +/–7.5 kHz or +/–15 kHz. ● 8-pole quartz filter and a 4-pole ceramic filter gives more than 80 dB rejection at 2X channel bandwidth. ● Frequency trimmers for each crystal. ● .2 to .3 μvolt for 20 dB quieting. ● Dual-gate MOSFETS and integrated circuits. ● Self-contained speaker and external speaker jack. ● Mobile mount and tilt stand. ● Anodized alum. case, 6" x 7" x 1-3/8

Model FMR-250-11 price: 135-180 MHz $109.95
181-250 MHz $119.95

Price includes one .001% crystal. Additional crystals $6.95 ea.

HOW TO ORDER:

All the preamps on this page are available only from Vanguard Labs. For receivers and converters, state model, input and output frequencies and bandwidth where applicable. Remit in full, including sales tax if you reside in New York State, direct to Vanguard Labs. Prices include postage by regular parcel post. For air mail or special delivery include extra amount; excess will be refunded. Send money order or certified check for faster shipment.

COMING SOON: .0005% crystal control for 2 meter transceivers for less than 25¢ per channel!

repeater. Each system requires something that another system may not. However, I will outline two systems (one for six and one for two meters) which I prefer. These systems use Motorola equipment exclusively. This is not to say that equipment manufactured by other companies is not entirely satisfactory. The reason that I have selected Motorola is familiarity, based on having worked with the equipment during employment with Motorola Communications & Electronics,that portion of Motorola which manufactures and sells the FM equipment. In fact the repeaters in the Dallas-Fort Worth, Texas, area utilize from a complete Motorola system to a hybrid of General Electric and Motorola with a little RCA thrown in for good measure. Each one of these repeaters operates very well.

My choice for a six meter repeater is as follows: A split-site with input and output frequencies separated by 100 kHz. The receiver site would utilize a "J-Pole" antenna feeding a Motorola "G" receiver. The audio output would be fed from the discriminator through a cathode follower to a 18 watt output (cut back to 10 watts) 450 MHz Motorola "A" transmitter operating on or about 449 MHz. This link transmitter would feed a small yagi antenna aimed towards the transmitter site. The squelch relay would be of the tube type described earlier. The timer would be electro-mechanical for good reliability. The control receiver would be a Motorola "A" 450 MHz receiver operating around 445 MHz feeding a two tone decoder. The tone decoder would operate the latching relay to enable the receiver link transmitter to be turned off and on by the control station. The control station would have audio override capabilities. The transmitter site would utilize a Motorola "K" or "J" transmitter (60W and 100W output respectively) cut back to around 50 watts. The receiver from the link would be a Motorola 450 MHz "A." The audio would be fed from the discriminator through a cathode follower to the transmitter. The squelch relay would be the same tube type as mentioned before. Proper identification with the repeater call sign would be accomplished by a code wheel keyed by the timer. The timer would again be electromechanical. The control receiver would be another Motorola 450 MHz "A" operating on a frequency 100 kHz above the control receiver at the receiver site (this is to allow a single control station with a two frequency transmitter to control both sites). The tones utilized would be different to avoid possible accidents. The tone decoder would be the same design as at the receiver site. The transmitting antenna would be another "J-pole."

The control station and logging station would be at the same location. The control station would consist of equipment capable of operating on the repeater input and output frequencies such as a Motorola L41GGB. The 445 MHz control transmitter would be either a 450 MHz "A" or, if obtainable an L44BBB consolette base station. The encoder would consist of four oscillators using telephone type toroids as the frequency determining circuit. The control link antenna would be a small yagi.

The logging station would consist of a receiver operating on the repeater output frequency feeding a stereo tape recorder recording at the lowest speed possible. The tape recorder is turned off and on by a squelch relay. The audio would be taken from the receiver through a cathode follower and fed into one channel. A command receiver would be tuned to either CHU or WWV (whichever gave the best 24 hour signal in the area) and its output fed through a cathode follower to the second channel.

My two meter repeater would be of the on-site variety. The antennas for both transmitting and receiving would be of the fiberglass "croppie pole" variety. The receiver would be a high band Motorola Sensicon "A" (this receiver has a front-end which incorporates either five or six cavities depending on the exact model). If needed, a cavity would be placed in the receiver antenna line. The transmitter would be either a Motorola "A" or "K" (both 60 watt output rating, differing only in that the "A" utilizes an 829B final whereas the "K" uses a 5894) cut back to 50 watts output. A cavity would be put in the transmitter antenna lead. The timer and audio circuitry would be the same as in the six meter units, as would be the control link. In all cases the power

supplies would be Motorola P8464 units. Also, both repeaters would be open to all amateurs.

As stated previously, units manufactured by companies other than Motorola will do an excellent job. The General Electric Progress Line units are used quite extensively as are RCA 450 MHz units. The prime concern is whether or not the units used meet the requirements of the particular system. In some systems very low power in the order of only two or three watts will do the job. In other systems a "quarter KW" (250 watt output) transmitter may be needed

Why the Repeater?

This article has progressed under the assumption that the decision to establish an amateur FM repeater has already been made. For the benefit of any hardy soul who has read this far and who has not made up his mind or who requires a little more knowledge as to repeater operation I have listed below some of the pros and cons of repeater operation.

An amateur FM repeater serves to greatly increase the usefulness of mobile units by increasing their effective range. A low power mobile signal is received by the repeater at a distant, but favorable spot and then retransmitted at a higher power level from a transmitter also located at a more favorable spot. The same can be said for portable and hand-held equipment. Using repeaters it is often possible for two one watt hand-held units to talk over ranges (including to each other) which high power base stations may have trouble communicating. The range of base stations is increased, especially when talking to mobile units which may be in poor locations regarding the base station. During band openings (and these DO occur) the repeater will hear and be heard by distant stations long before most base stations can be heard. For example during the Spring of 1969 the Tyler (Texas) repeater and the Tulsa (Okla) repeaters were hearing and being heard by FM amateurs over a great portion of the Eastern USA. The St. Louis repeater was heard in the Dallas – Fort Worth area, thus allowing two meter FM operators to work each other over large portions of the country.

Along with the good of amateur FM repeaters there also must be the bad. Some amateurs tend to use the repeater as a crutch. That is, they keep their equipment and antenna systems working only well enough to use the repeater. When the repeater is off for repairs or when operation on another frequency is desired, these stations are marginal if operative at all. Also, if a new location is tried for the repeater, amateurs who formerly were near the repeater and who have not maintained their equipment will suddenly become very unhappy because they cannot use the repeater without working on their equipment. Another problem is that two stations using the repeater can tie up the frequency for others within the range of the repeater. This can be solved by several methods, including use of alternate frequencies once contact has been established and of allowing short pauses for other stations to break in. Some repeater organizations limit the time which the repeater may be used for a single QSO. This, however, is distasteful to many amateurs. Thus, a little courtesy will do wonders for the usefulness of the repeater system. A third possible problem occurs when ac power is lost during an emergency situation. Since the repeater is very useful during emergencies, it should be provided with an auxillary power source independent of the usual ac lines (such as an automatic starting generator). Also, many mobile and portable units have only repeater frequency capabilities. This should be overcome by the incorporation of direct transmitting capabilities as well as repeater input.

Conclusion

All circuits included in this article are presently in use in either amateur or commercial FM repeaters. Since each repeater will have a slightly different requirement from any other an exact model is not practical. However, by using the circuits in this article along with the equipment locally available it should be possible to build an effective repeater for local amateur FM activity.

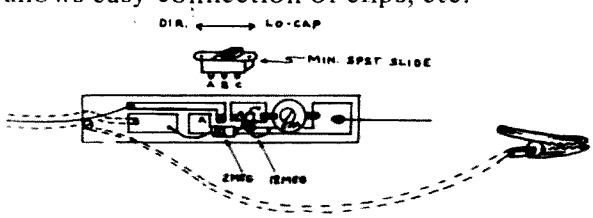
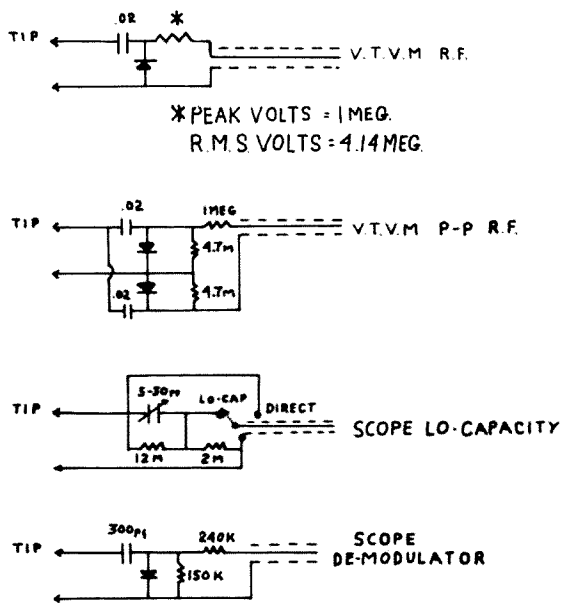
TEST PROBES need not be costly!



The proper test probe for your vtvm, FET, vom, or scope won't cost the usual $12–$19 if you are willing to spend an hour, a few cents, and follow the procedure below.

The usual stumbling block in home brew probes is not the circuitry but obtaining a suitable housing or probe body. The common *"Carters Marks-A-Lot"* felt tip pen appears to be the answer. These felt tip pens have an aluminum housing which is convenient to hold, is large enough to house the necessary components and, when the paper label is removed, has a professional appearance when assembled. Obtain an old pen (new will also work, if you must), and disassemble as shown in Fig. 1. Any of the

probes listed below may be assembled as the example in Fig. 2 (low capacity scope probe). The direct, low capacity switch – spst – may be incorporated or eliminated from any of the circuits shown.



Component mounting may be on a small single side etched board, or copper clad is easily cut with a hobby knife where straight line patterns are required. Vectorboard or thin plastic material may also be used. If plastic is used merely heat a small piece of wire and melt the component mounting holes where needed. The probe tip may be a piece of stiff tinned wire or a pin type connector. The use of the pin connector allows easy connection of clips, etc.

Caution: These felt pens are available with both metal and plastic caps. Should your pen have the metal cap it should be discarded. The tip may be isolated from the body by slipping a small piece of the inner insulation from a piece of RG58 type cable over the tip and sliding it down into the probe body. The ground lead is a 6 to 8 in. piece of shield from RG58 cable. Be certain the ground lead is secured to the probe housing as well as the circuitry and solder a clip to the free end.

The circuits shown below are designed for vtvm or vom with an 11 MΩ/V impedance. The scope probes are designed for scopes with 1 MΩ input.

In the following circuits, the dc blocking capacitors are 600V rated. The 1N55 diode has a piv rating of 150V and will safely handle 50V of rf. Once the assembled circuit

with connecting cable has been inserted into the probe body, push a small plastic cap, which has been drilled, over the cable, and on to the open end of the probe. Be sure the cable shield is grounded to the circuit ground as well as the probe body. A small amount of R.T.V. (rubber seal) inside the plastic cap will act as a strain relief.

Simple Base Supply For 6E Pre Prog or Prog Line From Junkbox Parts

Finding parts for an ac supply can be easy if you have in mind the "how to do it."

Here is a simple and quick way to lash together a supply that I found in the old junkbox.

T1 can be any heavy duty transformer (an old TV transformer is ideal as it usually has a high filament rating).

I built mine on a 19 x 5 in. rack panel, but a chassis box works well and can be installed in the mobile case.

Don't forget the caps across the relay contacts as they are very important. Their function is to prevent arcing of the relay contacts.

. . .K6VBT

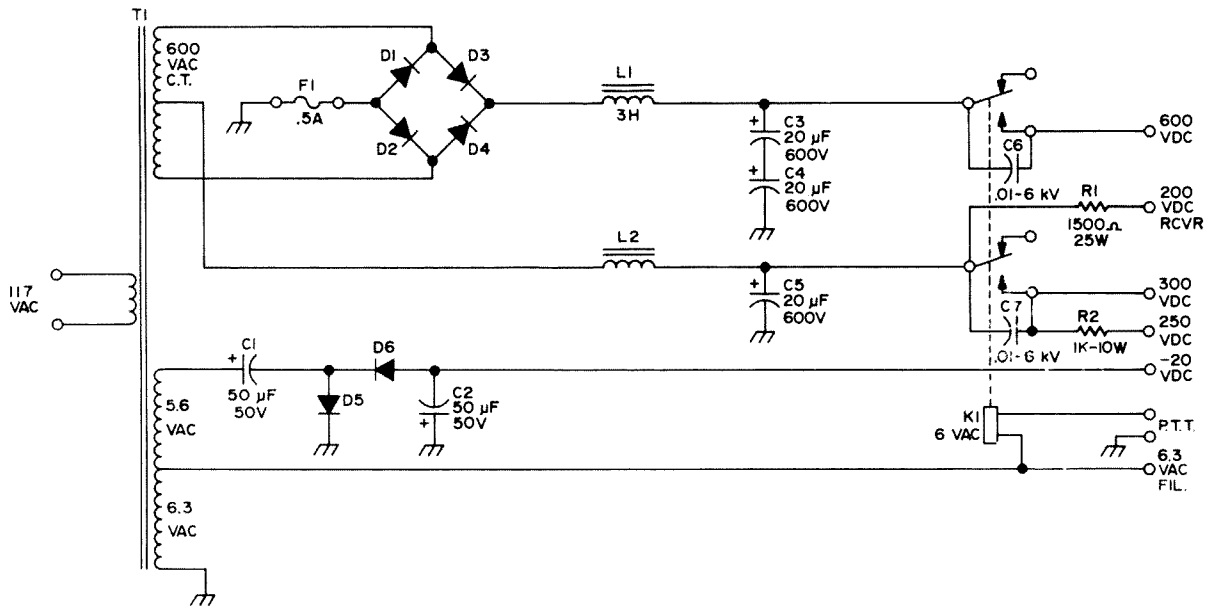

Fig. 1. Base supply. T1 – Merit P3059 or equivalent; Sec. #1 – 550–600V CT; Sec. #2 – 6.3V ac @ 3–5A; Sec. #3 – 5.6V ac @ 2–3A; D1-4 – 1000V diodes @ 1A; RL1 – DPDT relay 6.3V ac coil.

Zero-Beating with the Frequency Meter

After putting an LM-18 in service, I found it a nuisance to plug in headphones every time it was necessary to adjust the corrector control to produce Zero Beat at one of the crystal check points. I hooked up a phone plug to the plate winding of an audio output transformer, and then connected a small loudspeaker to the secondary winding. I leave the phone plug inserted in the LM phone jack at all times. After using this setup for a while, it occurred to me that the last few cycles either side of zero beat might not be audible, so I tried a parallel hook-up off the primary side of the transformer. The other end of the cable was connected to the Vertical input of an oscilloscope. Now, when adjusting the corrector control for zero beat, you will see low amplitude sine waves even after you can no longer hear the beat note. You tune out the sine waves until you have a perfectly straight reference line on the scope. The Heterodyne oscillator is then corrected to calibration much more accurately than trusting to the ear alone. The principle is not new, yet the idea may not have occurred to some people. Any old scope will do, as the frequencies are in the audio range.

Another bit of frustration occurred when trying to adjust the corrector knob. I would pass the zero beat point time and time again, due to the stiffness of the control. Remember, these units are built for ship-board use, and loose controls cannot be tolerated. I dug up a small vernier tuning drive, similar to the Jackson Planetary-Vernier drive, (about 5 to 1 ratio). I mounted this drive on a right-angle aluminum bracket and attached it to the LM using the two screws on the upper right side of the unit. Bore holes slightly oversize to allow for accurate alignment of the control shaft so that it will not bind. Cut out a portion of the bracket so the "High-Low" knob can be moved. The precise Zero beat adjustment can now be made very easily with the reduction drive.

RANDOM ACCESS PUSH BUTTON SWITCHING

There are many applications in which random selection switching is better than the sequential action obtained by using a rotary switch. For example, in television it is advantageous to be able to change quickly from one camera to another without having to go through a fixed pattern of selection. The interlocking push-button switches on the market today fill the needs of many applications; however, they do have a number of disadvantages. If one section of the switch goes bad, usually the whole assembly must be replaced, which is both time consuming and expensive. In some applications it is necessary to provide the same switching functions from more than one location, which means that some sort of a release device must be provided at unused positions. This is usually a solenoid that operates the release mechanism on the button assembly. This involves expense and space that might be better used elsewhere. What would seem to be most desirable is a system that would use relays to provide switching of the controlled circuitry, and would use individual push-buttons (illuminated or non-illuminated) of the single pole type to control the relays.

With this in mind, a circuit was developed which allows the following:

1. Use of any normally open momentary action switch.
2. Use of low voltage dc relays.
3. Use of as many circuits as are necessary, operated from one or more locations.
4. Easy expansion of the system.

The circuit is actually a variation of the self-holding type (Fig. 1) which is probably familiar to many. Once the "on" push-button is activated, the relay operates and its own "make" contacts then mantain the path first established. In order to release the relay, a normally closed switch must be momentarily operated, which breaks the path to the relay coil and allows it to return to its unenergized condition.

In the revised circuit (Fig. 2) the operate button (OP. . .) is momentarily depressed and the first relay to operate is RL. This is

the release relay, which comes up briefly until the capacitor C is charged; and current flow through RL ceases, allowing RL to return to its normal (released) condition. Resistor R across C provides a discharge path for the capacitor and should be small enough to let C discharge rapidly, but not so low as to hold RL operated. It can be seen that a normally closed contact on RL is in the hold path for all the other relays in the circuit. When RL operates, it opens the holding path for any other relay in the circuit, allowing it to release. This also stops the possibility of the newly selected K . . . relay from latching until RL releases. By choosing the operate and release times of RL and the K relays, make-before-break and break-before-make operation can be achieved.

The C capacitor must be empirically chosen for the particular relay used for RL. This relay must operate and release quickly, allowing only sufficient time for any operated K relay to release. Proper operation of this circuit is a matter of timing. Relay RL operates and releases as well as a K relay operating all in the short time interval that

the OP . . . switch was held operated. If illuminated push-button switches are used for OP . . . , the lamps for these can be connected across its associated K . . . relay. These lamps and OP . . . switches can be wired in parallel so that operation can be effected from more than one possible location.

AN ANTENNA and DIODE RECEIVER for 432 MHz

This discussion concentrates on one example of an antenna and one example of a diode receiver for 432 MHz. These units should serve to take you well up into the fascinating field of low-cost solid state microwaves which is just beginning to open up.

In transistors we now have the $1.50 plastics which operate on 1296 MHz, stemming as usual from the mass market of radio and TV, and who knows, if TV gets into microwaves perhaps we'll get microwave transistors for a buck.

Actually the process is already beginning, with the auto radio industry leading off with radar brakes, highway guidance and the like, up around X band. Detroit is talking (as usual) not in hundreds of systems but millions of systems. This may well bring us the X-band diode oscillators for under $10. They already can be bought for less than $20.

Interested? Let's plunge into the deal. You only have to add another oscillator and a broadband i-f strip to turn the diode receiver into mixer and make up a superhet receiver. For only $6 you can modulate the transmitter and who knows how far you can

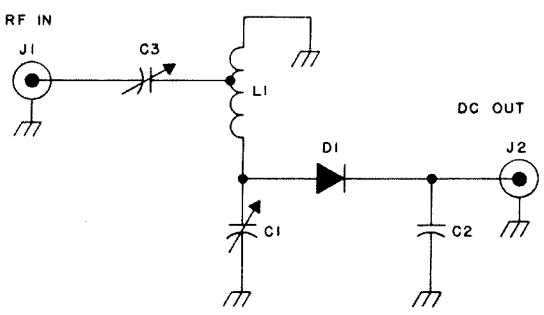

Fig. 1A. Schematic of diode receiver for 432 MHz.

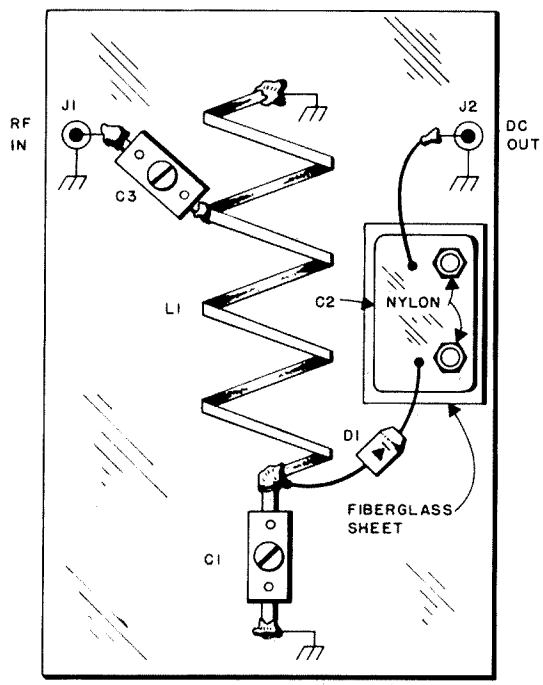

Fig. 1B. Lifesize drawing of the 432 MHz diode receiver layout.

QSO from mountain tops. The whole rig needs only a 98¢ lantern battery for power. *Use* your license and have more fun! I guarantee you no QRM, except perhaps when the band opens up.

Diode Receiver for 432 MHz

In order to check out the antennas you will have to have a receiver, and the design shown in Fig. 1 is just about as simplified as you can get and still tune well and be very sensitive. It works!

Using a parametric microwave diode it puts out 5V dc on J2 from a 432 MHz oscillator coupled to it with some 5 ft of RG-58 cable. This is using inexpensive RCA-type phono jacks for rf connectors by the way.

C1 peaked up immediately as soon as the oscillator was turned on. This type of receiver works well right up to 2500 MHz, although you should use a half wave line instead of a quarter wave at that frequency.

It seems almost funny to use a coil and shunt capacitor for tuning at 432 MHz, but ever since I tried it I find that it's hard to beat and certainly is handy.

You might say no precautions are needed for this one, and you'd be nearly right. C2 is a brass capacitor to ground, about 1 in. square. C1 and C3 are ceramic trimmers, or mica compression trimmers, about 1–8 pF.

Every little four or five turn coil I've wound so far has worked on this band. Start the rf input tap of L1 at one turn from ground, and maximize later. I'll admit the diode is a super-duper. It's a Schottky-barrier type, made by Parametric Industries of Winchester, Mass., costs nearly $3 and is worth every penny of it. It's good up to X-band, and is a good mixer also as soon as you want to convert this diode job into a superhet.

Standard Test Antenna for 432 MHz

This can also be quite a subject by itself so we'll just hit the essentials and show one good example of a working model.

On these frequencies you have the antenna right on your bench where you can put your fingers on it, tune it, add or subtract

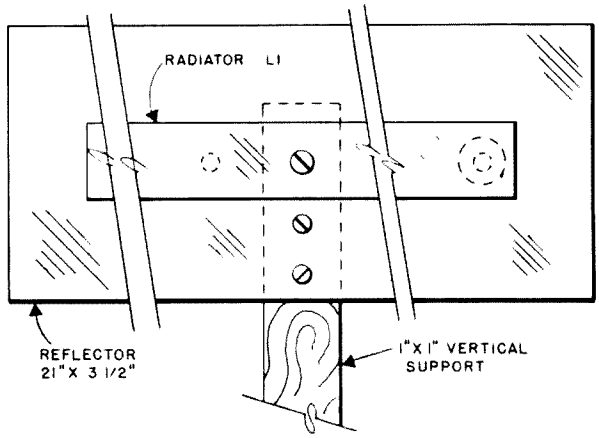

Fig. 2A. Front view of the test antenna 432 MHz.

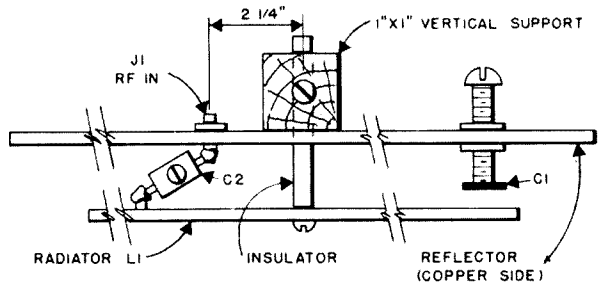

Fig. 2B. Top view of the test antenna for 432 MHz.

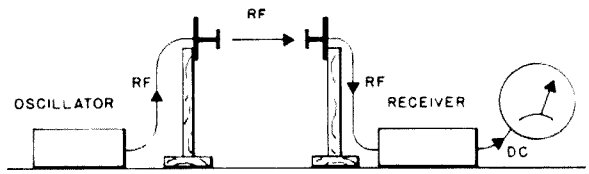

Fig. 2C. 432 MHz test setup and antenna tuneup.

lengths, change spacings, check for high and low rf voltage to be sure you do have a half wave, find the 50Ω points (there are two of them), vary the Q, change the directivity, measure the frequency of your oscillators, and find the antenna gain. All this without either a power meter or a frequency meter. I just don't happen to have either of those myself.

Lads working for large companies get their pictures taken checking little pieces of equipment surrounded by masses of expensive-looking test sets, meters, and scopes, mostly bought by Uncle Sam.

We're not making omnidirectional antennas, so let's start with a reflector of copper clad, large enough so it doesn't resonate, put

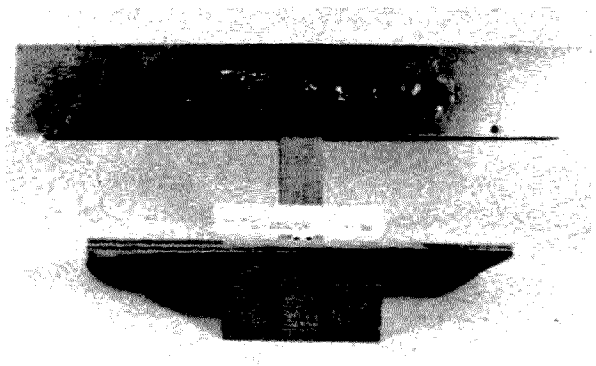

Photo of test antenna. Six inch ruler shows scale.

There is of course the physical need of moving C2 when you change the spacing of the radiator L1. I sometimes use a mica trimmer with a slightly S-shaped soft copper strap in order to be able to vary the spacing of L1 without changing C2. When an approximation is reached, and you get the feel of it, you can put in a permanent connection.

The value of C2 of course depends on the other parameters also. This is quite the usual order of things in R&D, where a number of variables have to be shifted around. For the experimenter the best way is by a series of a half wave radiator out in front, and see what happens. Make it a little short so you can tune it, and mount it at the center on an insulated push rod so as not to affect the voltage distribution, and install C1, a "penny tuner" near one end, as in Figs. 2A and 2B.

Bring your 50Ω rf input cable into the picture through the reflector on J1. This is an experimental antenna so you could make several holes for J1 in order to find the best match along the radiator. Either side starting from the radiator center will do.

C2 cancels the inductive reactance that starts building up the moment you uncover the center conductor of your feed cable to connect it to something. If you look carefully at this antenna and imagine it to be 270 ft long and suspended high over the field near your shack, you will see a certain resemblance to a Windham antenna. Just a resemblance, mainly in the one wire feed. When I have passed on to that Happy DX Mountain in the Sky, maybe this one will be called "The Old Hoisington Antenna."

The radiator is now ready to go to work for you. Bring the 432 MHz energy in on K1, put another standard antenna a few feet out in front and facing it, attached to the diode receiver, and watch that meter.

Tuning

For the radiator length you can start with some 10% less than a half wave in space which should give you nice tuning on C1. Generally you should use as small a capacity as possible for C1, just enough to peak the radiator. Be sure it *does* peak, that is, go through resonance with a maximum which then falls off on each side. Watch your receiver meter to see that this does occur.

Spacing

This is a trade-off like so many things in life, as well as in science. At ¼ wavelength spacing you will get the lowest Q, with very broad tuning. At very close spacings you can get a high enough Q to make an oscillator or an amplifier out of the radiator, but that's another whole story.

It won't take you long to find the spacing you need with the system test setup of Fig. 2C.

Finding the position of C2 along the radiator, L1 is next. When you start to work with this parameter you will see its interaction with some of the others such as its value in pF, which will be low, radiator length, spacing, C1 tuning, width of the radiator, and possibly more.

Table I. Antenna Test, 432 MHz

Reflector Size	Radiator Length	C2 in pF	Distance C2 to Center of L1	D, Radiator spacing from reflector D, Spacing Radiator to Reflector	Remarks, Tuning of C1. Also the Bandwidth
21" long, 3½ wide	11¼	Open.	2 1/8	7/8	Sharp
		Less than 2			
		2 to 3 pF		1½	Medium
		7 to 8 pF		2"	Broad

approximations. You set up one item, vary the others, set another value in, change some more, and after some time goes by, and if you're lucky, you begin to see the best range of values for each parameter. You're getting close then. Pretty soon, if your luck holds, although it may take hours or days, as with my 36 ft wide-spaced two meter yagi where it took weeks, you will reach the point where anything you do *drops* the gain of the antenna you are tuning up. Then you're real close. In fact you could very well stop there and check the gain relative to a dipole by the distance method, and you should then have a good test antenna.

Just to show you what you can learn about a radiator and sheet reflector in a short time, here is one test run that was performed on the antenna of Fig. 2A. The equipment test setup is shown in Fig. 2C. Two antennas as in Fig. 2A were used, and the changes made on one of them. Table I shows the result. A lot can be learned from just that one run using three settings for the spacing of the radiator from the sheet reflector.

1. With close spacing it doesn't take many pF to couple to the radiator. The radiator is "hot" and sharp in tuning and a small amount of coupling pF will cause a large reaction (energy feed).
2. As you go toward the ¼ wave spacing, the Q drops, and the radiation increases. Witness the increase in power at the receiver.
3. As you go *past* the maximum radiation point the Q is going down and the radiation drops also due to less rf on the antenna, and the antenna is also more broadband. This latter may be desirable from the point of view of the vfo lad chasing all over the band (this does not necessarily apply to the 432 band as yet!) but he just won't have the gain of the chap who peaks up and stays near that frequency.

Notice that several other parameters were not varied in this test run. After all, I said it was a short run.

If this gives you some ideas to try yourself, that's why I wrote it.

Professional Quality for the Professional Amateur!

High Performance 2 Meter Transmitter

The Finest Printed Circuit Materials and Exclusive Design Techniques Provide the Best in Professional Quality

• 10 WATTS • SOLID STATE • 8 CHANNELS • HIGH PERFORMANCE RECEIVER

- 8 Channels with Instant Push Button switching
- Solid State. Finest quality silicon transistors
- Netting trimmer for each receive and transmit crystal
- High quality mechanical filter for adjacent channel rejection
- Military-grade, glass-epoxy printed circuits
- serviceable design, compact construction
- Diode protected Dual-gate FET mixer
- 25 transistors, 1 IC, 1 MosFet, 16 Diodes
- Overload protected receiver R.F. stage

Model FM-3601—10 Watts. . **$299.95** **Model FM-3602**—25 Watts. . **$350.**

Each unit comes with 2 pair crystals (34T/94R and 94T/94R)

W2NSD *(continued from page 2)*

er? The Standard 146 comes with 34–94 permanently wired into place. So why make this a useless combination in all of the major cities?

Is it possible for repeater groups in each major city to get together and put up a 34–94 machine which will enable visitors using one watt units to have some fun and meet local amateurs? It needn't be a gigantic alligator, just something so that when someone comes to New York he will be able to talk a little. No other channel has the possibility of being, quite simply, a universal calling channel and meeting place for travelers.

If there is any mass movement to 52 for a simplex channel you can bet that crystal prices will drop even lower than they are at present. A 52 pair now costs about $7.50. If the crystal manufacturers are able to turn out thousands of them at a time the price could drop to about half of that. It's up to you.

Should 34–94 become a national calling pair, it is possible that an autocall system could develop. That would be nice too. As it is, in the larger cities, you have to check into a dozen or so repeaters when you are looking for one particular fellow since he might be using any repeater. Or none. So use the phone, right?

Down Links

Okay, the FCC is showing signs of becoming unfriendly and hardnosed about Techs above 147. Big deal. The whole two meter band should have been opened to Techs years ago – you know it, I know it – and the FCC knows it.

If the FCC has any bitch about the way amateurs are giving the Tech exams they should make their gripe public and work out a way to solve the problem. If the technical exam for Tech license is exactly the same as the one for the General license – and it is – then why should there be any difference between the two meter allocations for the Generals and the Techs? Particularly in the 147 MHz segment of the band there is no question of code or CW and that is the ONLY difference between the licenses.

Perhaps there is a little reason to keep the Techs out of the virtually unused CW band at the low end of 144, though little of the CW that does get used there is above the Tech 5 wpm speed limit. This part of the band swings into action during aurora and very slow speed code is the way you work via aurora, not high speed. Be that as it may, the FCC could certainly open 147–148 any time with no harm done to anyone – and they should.

Until they do open this part of the band for Techs, this is not a bad place to put repeater inputs for use by General class licensees where the repeater is down linked to a General class band such as ten meters or the upper part of 20m.

Say we take a 19–79 repeater and put a second priority input on 147.39 which, when used, would have its output on 79 and also on 29.68 MHz. This would get around the problem of Techs being repeated on 10m and keep some of the FCC engineers in charge with nothing better in this world from harassing us. It is too bad that some of them, like Atems in Detroit, have so little interest in the CB mess that they have time hanging heavy on their hands and spend large gobs of our money strictly enforcing almost unbelievable interpretations of obscure and long uneeded rules.

Hopefully your repeater group will take an interest in down links and set up some. This will greatly enhance the value of your repeater. If your group is interested in providing first rate emergency service then you can hardly refuse to set up a down link to the service nets on 40m, Midcard on 7255 and Eastcars and Westcars on 7258 kHz. A simple sideband transceiver connected to your repeater will enable this down link to be used for reporting emergencies. There are hundreds of ears monitoring these nets night and day so you will be able to expand the service you provide enormously by tying into the nets.

Links to 10m will enable you to work through your repeater and out to a western repeater – through a link back up to 2m again. That comes under the heading of fun.

Northeastern Repeater Association

The repeater groups of the northeastern part of the country are now mulling over the constitution and by-laws of the Northeastern Repeater Association (NRA), trying to decide whether they want to join or not.

There is no question that an organization of repeater groups is needed. Every time there is any sort of meeting announced the representatives of repeaters turn out in great numbers and anxious to get on with solving the many problems involved in coexisting. The reasons for some hesitation as far as jumping into the NRA have to do with its short, but checkered history.

The first meeting, held early this year in Pennsylvania, came as a surprise to most of the New England repeater groups, who were not only uninvited, but feel that the meeting was perhaps intentionally kept a secret from them. This meeting seems to have been prompted by a fear by a few people that the FM Symposium announced by 73 and hosted by the Worcester Radio Club would be a success. The idea apparently was to steal the thunder from the symposium, hence the secrecy.

The Pennsylvania meeting resulted in several important frequency allocation agreements and certainly was worth while from this aspect. The NRA was "organized" at this time with Gordon Pugh W2GHR as president and Bob Peterson K2IEZ as vice president. Since both of these chaps are extremely controversial in FM circles this choice spread more consternation than confidence among the New England repeater groups.

The second meeting of the NRA in Weston (Mass.) steam rollered over even the most sturdy voices of protest and did not increase confidence. Bob Waters W1PRI and Bruce Marcus WA1NXG, probably the two most controversial amateurs in New England FM, appeared to be working hand in glove with Pugh and Peterson. More consternation.

The third meeting, in Hartford in April, surprised those present when the announcement was made that the president was now Bob Waters and Pugh was vice president. Peterson had dropped out. The representatives of K1FFK on Mt. Greylock raised a very loud howl about Pugh being any officer of NRA at all in view of his actions with WA1KFX (see page 10, June 73). They felt that this was deliberate jamming of their repeater and that any individual who would do such a thing had no business having an office in a repeater association. The representatives of about 80 repeaters present for this meeting were not happy to find that the meeting was taken over almost entirely for the reading of a proposed constitution and by-laws of the NRA instead of getting down to brass tacks and trying to solve the problems that the groups had come there to work on. Many felt that the meeting was a tremendous waste of time.

After the meeting representatives of repeaters with special problems got together to see what could be done to solve channel problems. Pugh finally agreed at this time to shut down his Mt Snow repeater which was clobbering K1FFK a few miles away. A long hassle with Frank W2OCM came to naught when Frank refused to consider any negotiations, thus forcing the Bridgeport repeater WA1KGK to be the only one in New England not on a 600 kHz pair.

Two months after the April NRA meeting copies of the proposed consti-

THE TAMING OF THE HHRW

What is worse than having TVI? What is more shattering than a pink ticket from the FCC? Well, I'll tell you. An HHRW, that's what. You don't know what an HHRW is? Then read carefully, because you may be married to one. An HHRW is a *Hate Ham Radio Wife*. They come in all sizes, shapes and colors. The extreme species can be recognized by the fact that they find it necessary to bake a cake – using the electric mixer of course – or to do some very urgent sewing on a dress they won't be wearing for six months, always right in the middle of a rare DX contact. Should they come across a ground radial while working in the flower bed, they whip out their pruning shears and cut it into tiny pieces. Of course one consolation there is that it was the ground radial that got it and not you! Their favorite topic of conversation is telling you about the many uses the ham shack could be put to if you would just "get rid of all that radio junk."

Now I am a HWFO – a *Ham Wife of the First Order*. That is a license toting ham XYL. And I am going to give you a few pointers on how to turn that HHRW of yours into an HWSO. A *Ham Wife of the Second Order*. That is a ham wife who doesn't actually have a license, but neither does she despise your hobby. As a matter of fact her attitude varies from "live and let live" to a genuine interest. Either way she has learned to accept you with as much grace and aplomb as the situation permits, for better or worse and ham radio. How do I qualify to give you these instructions? Well, even though I acquired my Technician license before I married W7UVI (I don't think he would have married me otherwise) there were times – and still are a few – when his hobby irritated me to death. So you can imagine what these same things must do to a bona fide HHRW. So if you want to hang on to your wife *and* your radio, pay close attention.

Rule No. 1. Don't call CQ five minutes before you are supposed to go shopping, to the movies, or to your mother-in-law's for dinner. The guy you contact will no doubt be running the new Starduster 13, the greatest rig to hit the market, and it's the first one you have heard on the air. Now I would judge this contact to be worth at least thirty minutes. You only have five, remember? Another possibility is that the OM who comes back to your CQ just happens to have served on the U.S.S. Goldfish, the very same ship you served on, and about the same time, at that. This contact is worth at least one hour. Or consider this: You call CQ and get an answer. You manage to give and receive all the vital statistics . . . QTH, handle, signal report and sign, all in five minutes. Aren't you proud of yourself? You reach to turn the rig off – but hark! What is that you hear coming faintly through the QRM? Could it be? Is it possible? YES, it is! An XYQØAB in Lower Slobovia calling you! You have never even heard one, let alone worked one. But as you reach for the mike to answer him, the hairs on the back of your neck stand up. A quick glance over your shoulder confirms your suspicions. Your HHRW is standing there looking at you and saying, without even opening her mouth, "If you touch that mike I will *kill* you! We are leaving NOW!" So why risk a five minute QSO? If you, like my OM, find yourself compelled to call CQ at these inopportune

times, try this therapy. Go into the ham shack but don't turn on the rig. Not even the receiver. Grab a dust cloth and start dusting. How do I know your shack is dusty? Because no self-respecting HHRW would set foot in a ham shack, let alone dust it! Or you could pick up the tools you left out the night before when you were troubleshooting the rig. Try sitting down and writing out QSL's. But whatever you do, don't pick up that mike!

Rule No. 2. As you come home one evening to find the baby crying, the older harmonics fighting, and your wife throwing out a batch of cookies she burned because the stupid timer wasn't working – don't head for the seclusion of your ham shack. (That is, if you want to cultivate an HWSO – if you enjoy living with an HHRW, then go ahead.) If you choose the former, here's what you do. Disengage the screaming toddler from your XYL's leg and shut him up. A cookie will usually do it, if you can find one that isn't charcoal. Then send the feuding harmonics outside, or to their rooms, or anywhere out of their mother's hair. You might even try to fix the "stupid" timer. Later, when the kids are in bed and your XYL is ensconced in front of her favorite TV program, you can enjoy your hamming with the knowledge that you aren't adding fuel to your HRRW's dislike of your hobby.

Rule No. 3. This involves the source of all evil . . . money. Or the lack of it. If your wife needs a new coat, the harmonics all need new shoes and you haven't paid last month's doctor bill, don't go out and buy a new Fantastic 4 Transceiver or a new HANDY, DANDY-SOOPER-DOOPER tower. After all, what would you rather have, these frivolous things or a wife? On second thought don't answer that. Just try to use a little common sense and a hell of a lot of will power when it comes to spending money on your first love. Yes, we XYL's know it is your first love, but we appreciate it if you don't keep reminding us the fact too often.

Now if you follow these few rules I can't guarantee you will change your HHRW into an HRSO, but I think it's worth a try, don't you?

$5 PREAMP COMPRESSOR

Recently I purchased an HW-100 Heath transceiver, and with it came the need for a mike. I had one, but it was a low-Z high quality thing, and I was faced with the problem how to match this to my high-Z input of the HW-100. I made up a transistorized preamplifer from a circuit in the GE transistor manual. This furnished me with a high impedance output and more signal than I could use.

I had heard about speech compressors, but never thought they could do anything for me. Because after all, my rig had an effective alc circuit, and that should do the trick. And then, one Sunday morning on 10m, I listened to a German station demonstrating his voice transmission with and without a speech compressor. That did it! What a difference it made. The S-meter gained 6 dB and his voice punched through the QRM. It wasn't even funny!

I dug through all my 73 back issues and found two articles on the subject, both by W2EEY (March and June '69). One circuit was his own design, the other a review of a commercially available unit: the "Caringella ACP-1." The specs on the Caringella look extremely good and the circuit is very well designed, but it was priced in the $20 bracket as a kit and rather large. It couldn't be built into an existing transceiver.

The next thing I did was measure just how much compression is needed by watching my voice amplitude on a storage scope. I could see intense and weak speech passages precisely. I found maximum amplitude differences to be 1:20, or 26 dB. So I went ahead and built a Clipper-type compressor that gives easily 20 dB compression without too much distortion. This thing is less complex, easy to build, cheaper, and physically much smaller than other units. I built it on a 1¼ x 1½ in. circuit board, and could squeeze it easily into a corner of my rig. The thing draws 1.8 mA, which I stole from the 250V B+ via a dropping resistor. If you want to play it safe you can stick a zener in there too. The circuit is flexible and features a few minor things that others don't. It takes out low frequency ingredients, particularly below 150 Hz, which makes voices sound as if they came from the bottom of a barrel. Also, gain can be chosen to suit any type of mike, low and hi-Z mikes can be used with output levels from a 0.5 mV–10 mV/microbar sound pressure. Even ceramic mikes with 100 mV output can be used by feeding the signal in at a different point of the preamplifier.

The preamp-compressor has an input impedance of 50 kΩ and output impedance of 100 kΩ. Frequency response (Fig. 1) is flat from 250 to 3500 Hz and drops off softly to –20 dB at 60 Hz and 20 kHz. Input sensitivity is defined to yield an

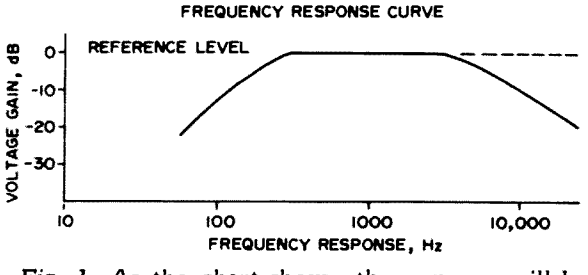

Fig. 1. As the chart shows, the response will be flat in the voice range.

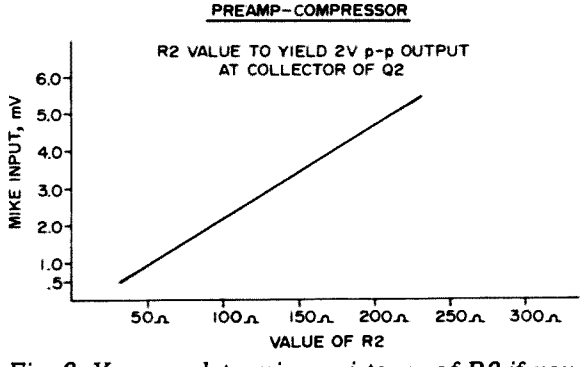

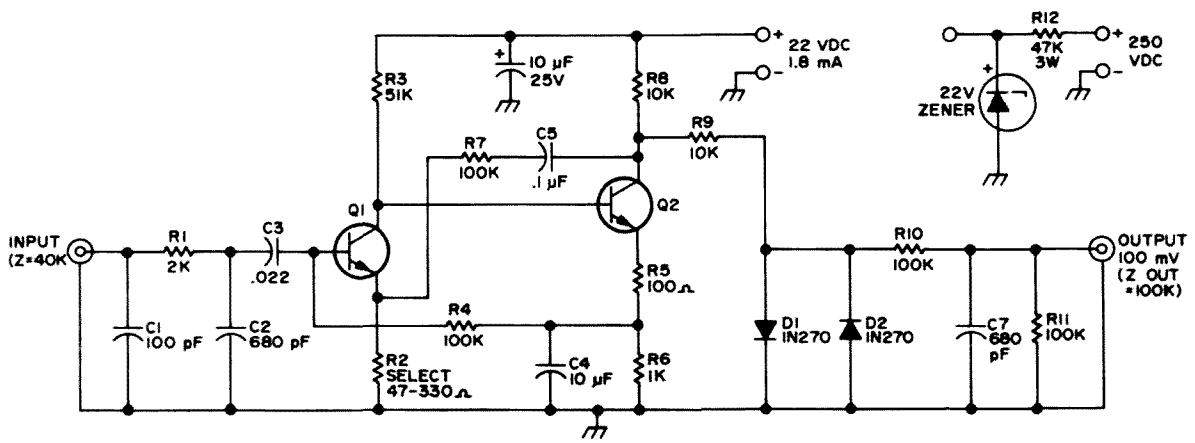

Fig. 2. You can determine resistance of R2 if you know the output capability of the mike you'll be using.

1-Q1 & Q2 ARE Si NPN TYPES, hfe 30-120, VCBo 45V OR EQUIV.
2-SELECT R2 FOR DESIRED GAIN.
3-IF NECESSARY, CHANGE R4 TO YIELD 10-12 VDC AT COLLECTOR OF Q2.
4-IF LOWER OUTPUT IS DESIRED, CHANGE R10-R11 RATIO.

Fig. 3. Schematic, preamp-compressor.

output of 2V p-p at collector of Q2. The gain required can be set by selecting the proper resistance value for R2, emitter resistor of Q1. (See Fig. 2.) If the rms mV output from your mike is known you can select proper emitter resistor from this graph. If mike output is unknown just try 100Ω for a ballpark value; it will most likely do. The whole gain selection is of some importance because the signal at collector of Q2 should not exceed 2V p-p by much. If it does there will be some distortion at the compressed output.

C1, R1, C2 act to filter any rf that gets into the input. C3 couples the signal into the base of Q1. C3 should be a low-Q type capacitor such as an electrolytic to make sure it doesn't pass rf too easily. Q1 amplifies the signal to a 150 mV level. If R2 is increased, gain of that stage decreases and you can input a larger mike signal and vice versa. Q1 is bootstrap-biased from E of Q2 which results in very stable and low distortion amplifier stage. The signal is dc coupled from collector of Q1 to base of Q2. Q2 collector sits at 10–12V dc, which can be influenced with bias resistor R4. Depending if you chose a higher or lower gain Q1 and Q2, this R4 value has to be changed somewhat to get the 10–12V at no-signal. R7 and C5 provide some negative feedback for bass and treble. From the collector of Q2, the signal passes R9 and C6 and sags down via D1 and D2. Here it is important to use the right diodes: they have to be high conductance germanium types which break out easy and gradually. 1N270s will do nicely, and some computer diodes are very suitable.

These diodes will not clip signals as small as 150 mV, but will definitely break out as you increase the signal level. The working resistor R9 and capacitor C7 will smooth off the clipped signal so it looks like a sine wave again. An excessive signal before R9 will cause significant distortion which can be heard easily. The wave shape at the output will look more and more square if the level into the clipper-section becomes too large.

R10 and R11 attenuate the output level to 100 mV, but can be attenuated to other values as well. C7 helps shaping the output wave shape and cuts treble some more. It also shorts any rf at this point.

Since I have been using this compressor over the past few months I made a number of tests on the air, demonstrating my voice without and with compressor. All reports gave me positively more audio punch, and in several cases I could only be copied solid with a compressor – and not without. On DX QSO's voice clarity could not be distinguished except for loudness, whereas local hams in two cases reported a somewhat bassy voice.

So I am sold on it now. I like it because I can sit back and speak gently into the mike even at a 1 ft distance and still observe the output power meter bounce right to the end continuously.

Push-to-Talk for the Sixer

AND OTHER MODIFICATIONS

Breathes there an owner of the "Benton Harbor Lunchbox" who hasn't made some modifications to suit his own needs? My Sixer is mounted in a Volkswagen for mobile operation, and I found it hazardous while driving to manually change from receive to transmit using the panel-mounted switch. So, out came the rig for a push-to-talk modification. And while the little fellow was sitting on the workbench with its innards exposed, a few others changes were made: a spot switch and receiver bandspread. These modifications, plus others that had been made from time to time (the output meter and front panel mounted crystal socket were installed following articles in various ham publications over the past few years), have made the Sixer a real joy to operate. I'm sure the basic ideas described here would apply to the Twoer as well.

Author's "Sixer" ready for mobile operation. New panel is not essential but helps to cover up hole left by removed transmit-receive switch. Note new tuning scale.

Push-to-talk capability was achieved by replacing the manual transmit/receive switch with a 12V dc 4PDT miniature relay. Owing to the nature of the filament circuit, once you've converted the rig to PTT, you can't operate on 115V ac, because the filaments are fed in parallel from a 6V winding on the transformer, and when operating from 12V dc, they are arranged in a series-parallel circuit. Since I intended only mobile operation, this situation did not bother me. Since the filaments operate on 6V, a 6V ac or dc relay across the filament string may be used for the PTT, depending upon whether you prefer fixed or mobile operation. People who use these ubiquitous rigs both at home and in the mobile might try installing a rectifier in the filament string before an appropriate dc relay.

The relay is mounted upside down and against the front skirt of the chassis, using contact cement. No socket is used. The

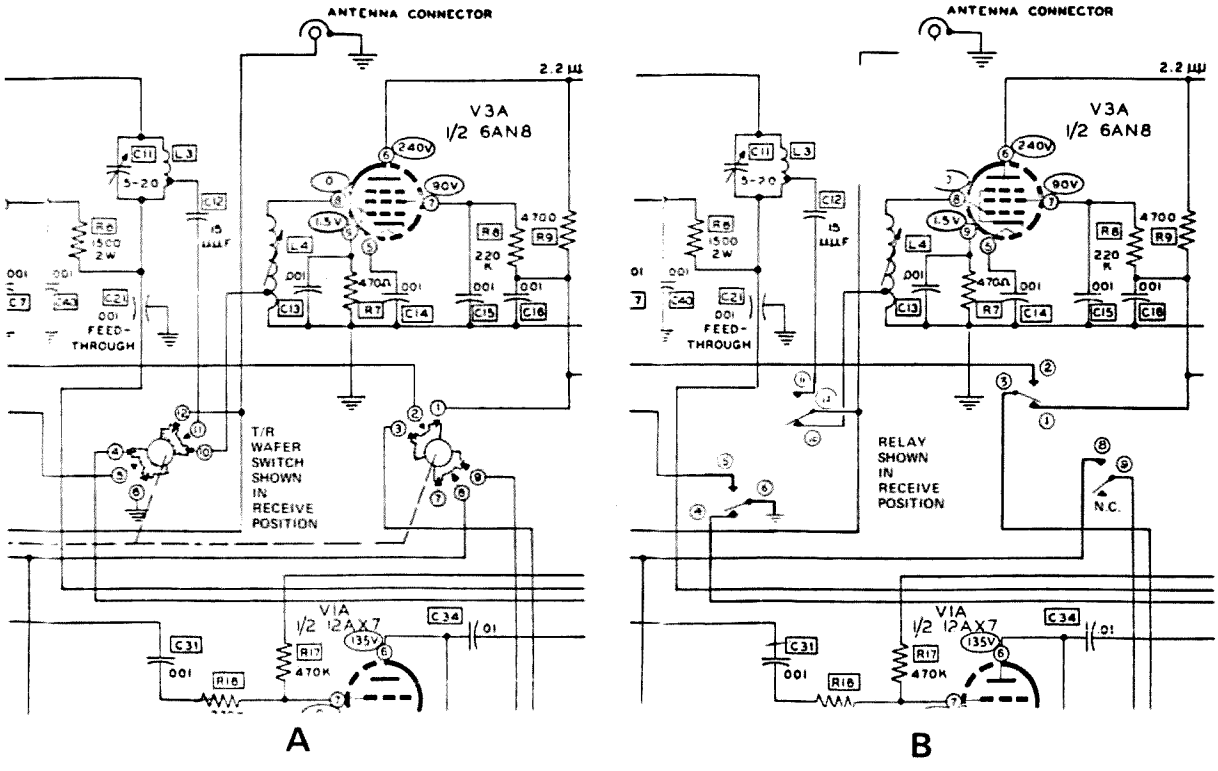

Fig. 1. (a) T/R circuit before modification. T/R wafer switch shown in receive position. (b) T/R circuit after modification. Relay shown in receive position. Numbers in circles around relay contacts correspond to original terminals on wafer switch.

relay occupies the same area originally taken by the wafer switch (see photo), which makes wiring rather easy; just use the wires you removed from the wafer switch and connect them to the relay. Figure 1 shows a "before and after" wiring scheme based on the original Heathkit schematic diagram.

I was a bit apprehensive about making this change, as I felt the intercapacitance between close relay contacts might adversely affect rf output. Before making the change, I measured rf output across a 50Ω dummy load, then repeated the measurements after the relay was installed and the final amplifier retuned. Using my simple measuring techniques, I could detect no reduction in rf output.

Voltage to operate the relay is taken from the 12V filament circuit. Figure 2 shows the relay actuation circuit. The relay is operated by a microphone with a push-to-talk switch built in. A suitable microphone jack can be installed in place of the original jack on the front panel, or on the rear skirt, if you want to add the spot switch described next. Since my Sixer has an output meter, I removed the meter jack and reamed out the hole on the rear skirt to accept the microphone jack. Be sure to use a high impedance microphone.

I can't say the spot switch I added lets you *pinpoint* your crystal frequency on the dial, owing to the very broad tuning characteristics of the receiver. But it is a help when there are several stations around your operating frequency, and you want an inkling of where your signal is going to fall. A SPST (momentary-make or standard toggle) switch is mounted on the front panel and connects a 47,000Ω, 1 watt

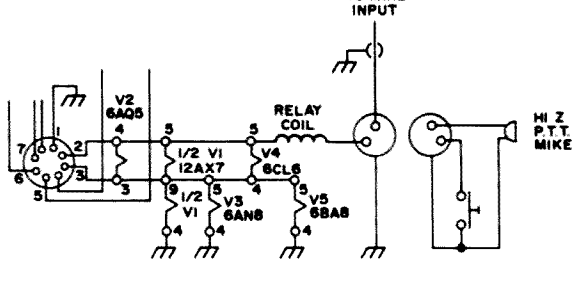

Fig. 2. Relay actuation circuit.

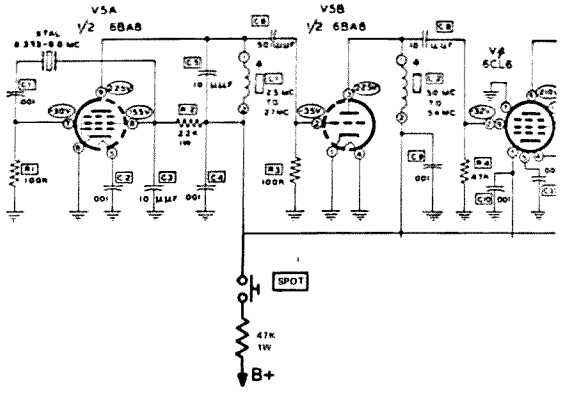

Fig. 3. Spot switch circuit.

resistor between a source of B+ and the plate of oscillator tube V5A, as shown in Fig. 3. The resistor keeps the plate voltage low enough so the oscillator output doesn't overload the receiver, and tends to make spotting a bit more accurate. (Even with this reduction in output, the spot signal covers about 15 degrees of tuning dial rotation!) The broad tuning and lack of selectivity led to the next modification – bandspread.

Bandspread

Most of the activity on six meters in my part of the country seems to fall between 50.2 and 51 MHz, with a great concentration of stations around 50.4 MHz. With the Sixer covering 50 to 54 MHz, this meant that most of the stations I work fall within a two degree span of the dial. Ridiculous!

I very carefully removed one of the two rotor plates from the receiving tuning capacitor, then soldered a 1.5 to 8 pF trimmer across the capacitor terminals. I adjusted the trimmer so that the receiver tuned from 50 MHz to around 52 MHz.

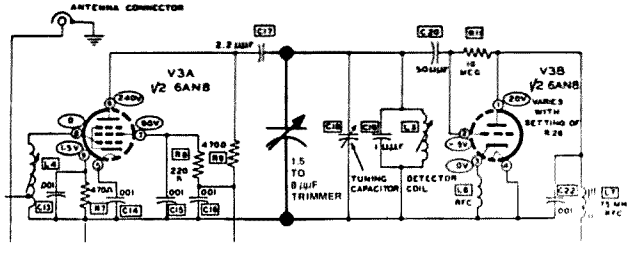

Fig. 4. Bandspread circuit.

PAINTING METER BEZELS

William P. Turner WAØABI
5 Chestnut Court
Saint Peters MO 63376

One of the major problems confronting the homebrew artist in making his equipment look as if it were custom-constructed is the American standard black meter bezel. If you happen to like black equipment you are in luck, but if you are partial to green, grey, or brown . . . well, sorry about that.

There is a way of matching any panel color. I stumbled into it quite by accident, after looking high and low for a dark green meter to match SB series green. The same approach is equally applicable to the usual clear plastic bezels found on imported meters.

Your local hobby store, 5 & 10, or drug store sells a paint intended for use on plastic model cars, airplane, and the like which works beautifully on meters. The color selection is quite wide and if you can't find exactly the shade you need you can always mix two or more colors. The answer to my particular problem was one jar of "leaf green" and about 3/4ths of a bottle of black. The price is low, so you needn't worry about the cost of experimentation. This type of paint is very forgiving, it being almost impossible to leave brush marks. Nonetheless, use a good brush and mask off the area to be painted if you hand isn't steady. Your project is guaranteed to look much more professional.

Audio Distribution Control and Phone Patch

Some time ago I decided that I was missing out on some of the fun of amateur radio due to the lack of a phone patch in the station inventory. Therefore one was constructed using junkbox parts and incorporated into another piece of equipment under construction at that time. However, the performance left something to be desired in that the hum level was high (no hybrid transformer in the junkbox), there was no way to monitor the amount of audio being fed to the phone line, and operation required disconnecting cables from the receiver and transmitter, reconnecting them to the phone patch, and reversing the procedure to return to normal operation. A recent redesign of the station made the original equipment which contained the phone patch obsolete, thus giving me a good excuse to redesign and rebuild the phone patch into a separate enclosure.

Front view of Audio Distribution Control

Rear view of Audio Distribution Control.

The audio distribution control unit described here is designed to be used as a phone patch, audio distribution system, and control of transmit/receive functions. Connections to the desired equipment are made by front panel lever switches which incorporate a lamp and different colored filter for each switch position. Different colored filters are supplied with the switches allowing those in different positions to be

color coded similarly when connected for normal operation, phone patch, etc. No extra controls are included for audio level adjustment, since this can be done at the receiver and transmitter. A VU meter is available to assure that the audio level being coupled to the phone line is not above that specified by the telephone company. The meter operates whenever a signal is applied to the hybrid transformer and may also be used to monitor the tape recorder input and output. When S2 is in the Aux/Patch position, the microphone input is disconnected from the transmitter and a DPDT relay is activated. Each of the two activated relay contacts are connected to three terminals on the rear panel and to ground. This arrangement allows transmitter power relays, receiver muting relays, and antenna relays to be activated by the audio distribution control unit when they are connected to the terminal board on the rear panel. This is a good method to activate the transmitter and auxiliary equipment for RTTY operation.

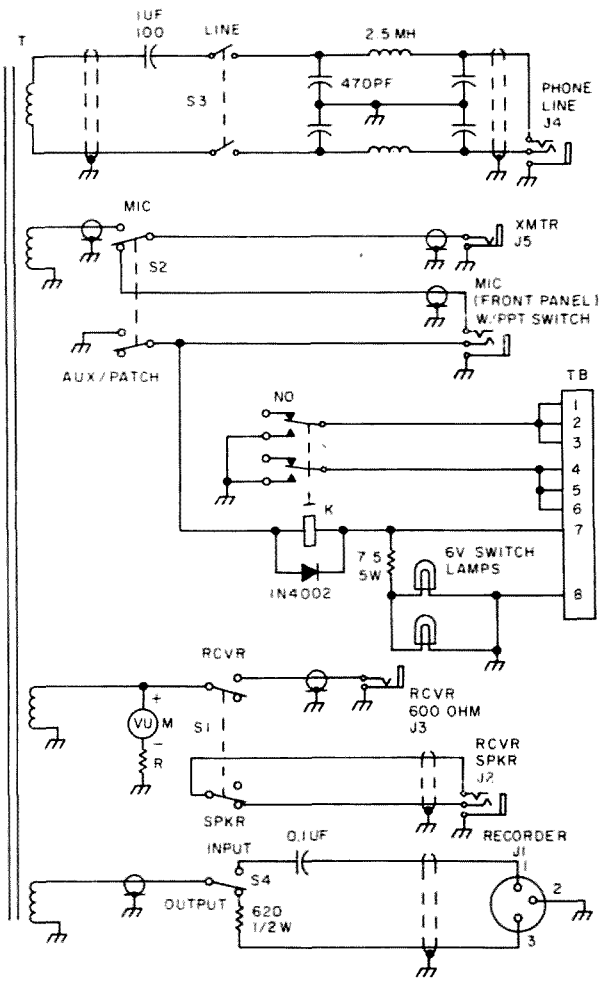

Fig. 1. Schematic of audio distribution control: T – c111 Telephone Retardation Hybrid Transformer, Herbert W. Gordon Company: $5.95. K – 12V, .13A, Sigma Relay Number 50F2, Allied Radio; $3.60. Bottom Plate – Bud 7 x 11 in., Number BPA-1594, Allied Radio; $.90.

Construction

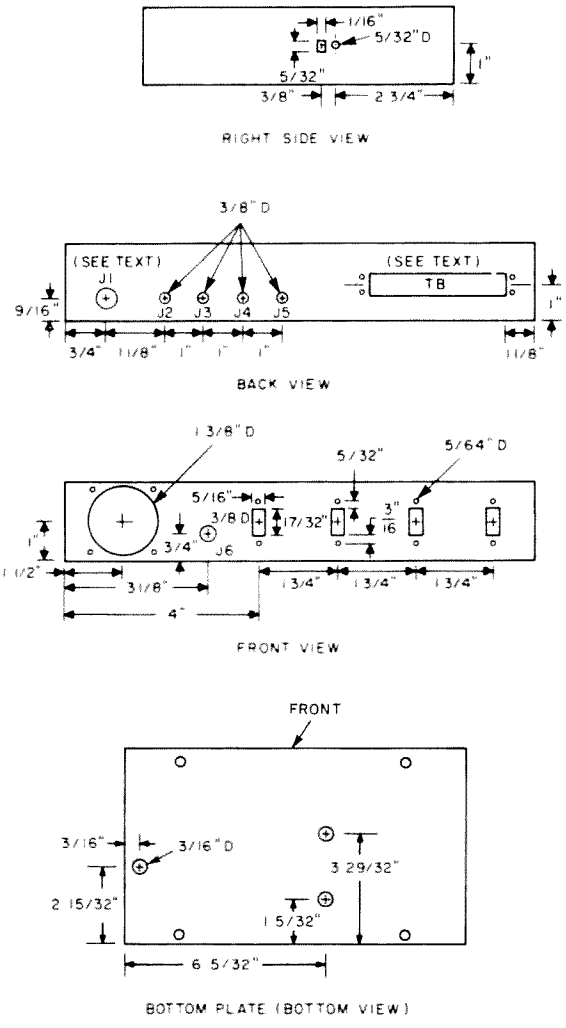
Although there are many different approaches to construction, the following procedure assures that no necessary steps are left out and that the end item presents a good appearance as well as being functional.

Fig. 2 shows the chassis and bottom cover with the necessary measurements for drilling. All views of the chassis are shown with the open side down, and all measurements are to the center of the openings to be made. Before starting to make measurements, mark the chassis for front, back, and right side. Beginning with the right side, mark and drill the relay mounting screw hole. The small rectangular slot, which keeps the relay from turning after mounting, may be made by drilling one 1/16 inch hole on either side of the center point and squaring with a small flat file. Hold the relay in mounting position to be sure that the holes match, then clean all burrs from the edges of the openings.

Mark the rear of the chassis for the jack openings as shown. The diameter of the tape recorder jack, J1, will be determined by the type of jack used. It may be a normal 3-connector jack, 3-connector microphone jack, or European-type jack as shown in the picture of the audio distribution control unit

Drill the holes for the jacks and assure that they are large enough before deburring. The terminal board, TB, is fitted with wrap-around posts which extend through the chassis. Two methods, depending on the

tools available, can be used to make the necessary opening. If a metal nibbling tool is available, mark a horizontal line 1 inch high and approximately 4 inches long from the right-hand edge of the chassis. Make a mark on this line 1 1/8 inches from the chassis end. Holding the terminal board to the rear of the chassis so that the wrap-around posts are on the line and the right hand terminal is approximately 1/16 inch to the left of the 1 1/8 inch mark, make a point on the horizontal line approximately 1/16 inch to the left of the left hand terminal. Drill a 1/4 inch hole anywhere between the two points on the center line, and use the nibbling tool to make a rectangular opening between the points as shown on the diagram. Hold the terminal board to the chassis and mark the points for drilling the mounting screw holes, assuring that the wrap-around posts are



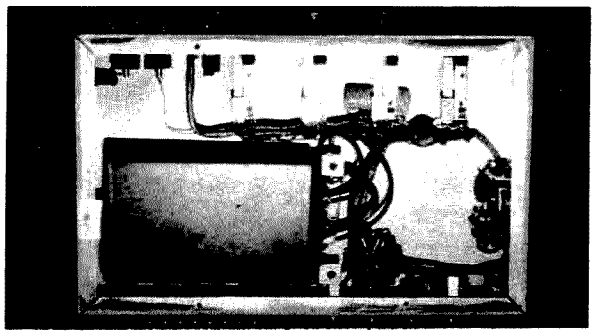


Fig. 2. Right side, back, and front, bottom plate chassis layout.

Bottom view with cover plate removed.

centered in the opening. Clean any burrs from the edge of the opening. If a nibbling tool is not available, hold the terminal board to the chassis so that the wrap-around posts are on the horizontal line and the outside raised Bakelite insulator of the right hand terminal corresponds to the 1 1/8 inch mark on the line. Make points on the line at the center of every wrap-around post and drill 1/4 inch holes at all these points. Hold the terminal board to the chassis and mark points for drilling the mounting screw holes, assuring that the terminal board is parallel to the chassis and all wrap-around posts are centered in the holes. Deburr all openings.

To mark the front panel for drilling, measure 1 inch from the bottom edge of the chassis and draw a horizontal line from one end of the chassis to the other. Make cross marks on this line at all points corresponding to the measurements on the diagram. Check the diameter of the meter housing before making the hole. Points for the meter mounting screw holes can be marked where the screws touch the chassis when the meter is partially inserted in the opening. Be sure that all screws are perpendicular to the chassis and meter plate and the meter is in the correct position before marking the chassis. An alternate method is to make a paper template from the meter or use the cardboard mounting strip from the package. The hole for J6 is drilled similar to those on the rear panel. The openings for the switches may be made by drilling a 1/4 inch hole on the point and using files or nibbling tool. In either case lines designating the perpendicular sides of the switch openings should be drawn on the chassis to preclude making an angular hole. Points for drilling the switch mounting screw holes can be found by inserting the switch lever through the hole from the outside and marking through the

holes on the mounting plate. Be sure that the switch is right side up when inserted, if the chassis is in this position. File all sharp edges and deburr all holes.

An additional three holes are necessary in the bottom cover for mounting the transformer. Mark one long side of the cover "front" after placing it with the bottom side up. Make all measurements with the front side of the cover facing away from you as shown in the diagram. After marking the left edge hole, place the cover on the upside-down chassis, assuring that the front of the chassis corresponds to the front of the bottom cover. Square the cover on the chassis and clamp in position before drilling. The holes may be drilled separately if clamping is not possible. The diameter of the two center holes will depend on the size of the screws to be used. Their length should not be over 1/4 inch. Self-tapping metal screws should be used for attaching the bottom cover.

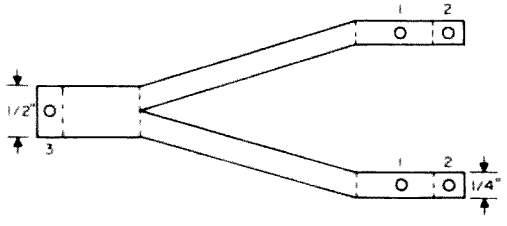

Fig. 3. Transformer bracket drawing.

The shape of the hybrid transformer presents some mounting problems. To overcome these problems, the clamp shown in Fig. 3 can be made from thin aluminum sheet, tin, or some similar material. Exact measurements will depend on the material used, since a lighter metal will bend easily without much loss in dimensions. The V-shaped section fits over the flat top side of the transformer, then both ends are bent down. The holes designated by the number 1 on the diagram are drilled in the center of this section to fit over the bolts on the base of the transformer. The original nuts are used for fastening. Sections numbered 2 and 3 are then bent up so that they are flush with the bottom of the transformer. Place the transformer with clamp attached on the inside of the bottom plate so that sections numbered 2 on the clamp equally cover the center holes and section 3 covers the hole drilled on the edge of the plate. Be sure that the transformer is parallel to the edges of the cover before marking sections 2 and 3 through the bottom plate holes. Drill holes corresponding to screw size and deburr.

Wiring

The wiring of switches always requires concentration and seldom is completed without at least one pair of wires reversed.

A ground bus wire is used at the switches for the connection of the shields of all audio cables terminating at the switches.

As can be seen from the schematic, the phone patch output to the transmitter is direct. For transmitters with high impedance inputs, a matching transformer or transistor preamp will probably be necessary. A diagram for rewiring the first audio stage of the transmitter is included with the hybrid transformer when supplied by Herbert W. Gordon Company. This solution may assist builders with high impedance tube input stages. The .1 μF capacitor on S4 matches a tape recorder input impedance of 2 kΩ while the 620Ω resistor will allow the transformer to see an almost equal impedance with a slight loss of gain due to the mismatch of most recorder outputs. However, gain is not a problem since regulation at the recorder provides more than enough. These values may be changed to suit the builder's needs.

Mount all switches in the chassis, using one screw for each. Since the chassis is upside down, be sure that the switches are the same way. Push the VU meter into position, but do not fasten. Loosely mount all jacks, the terminal board, and the relay.

Cut a piece of number 12 or 14 copper wire or bus wire approximately 1 inch longer than the distance from the first to the last switch. This ground bus should run along the rear of all switches about 1/4 inch from the bottom contacts and all cable shields should be soldered to it. All audio cables should run along the rear of the switches to a point in front of the transformer.

The transformer may be temporarily placed upside down in the chassis and a pencil line drawn parallel to and approximately 1 inch in front of the transformer terminals. All audio cables from the switches to the jacks follow this line to the rear panel where they branch out to their respective jacks.

If cable lacing or clamps are to be used, remember to leave enough slack at the switches, places where the cable run turns,

and the jacks. Begin the wiring with the front panel jack, J6, and continue with the other wiring. The filter components for the phone line may be mounted behind the jack, J4, and the two-conductor shielded cable from the filter to the switch.

The capacitor and resistor for the recorder lines may be mounted between the switch and shielded cable. After completing the audio cable hookup from the switches to the jacks, the audio wiring from the switches to the transformer can be done.

Measure the meter resistor from the negative meter lug to the closest meter mounting screw and cut the leads to this length. Shorten one lead and connect to a solder lug to be placed over the meter mounting screw. Do not connect the meter at this time. After all audio cabling is completed, with the exception of the transformer connections, a continuity test should be performed with an ohmmeter to assure that all connections are correct. When this check has been completed, the cables, with the exception of that section of the cables leading to the transformer, may be laced or tied with cable clamps.

Wiring from the relay to the terminal board should be done next. Do not solder any wires to the terminal board posts until so stated. Keep the wires along the bottom edge of the chassis.

A wire from the open contacts on the relay can be run to the ground bus and soldered. Run two wires from the switching relay contacts to terminals 2 and 5 on the terminal board. Mount the 7.5Ω resistor on the bottom edge of the chassis and bend one lead to pin 7 on the terminal board.

Place a piece of spaghetti on this lead. Run a wire from the remaining side of the relay coil to pin 7 on the terminal board. Attach one wire to pin 8 and one wire to the other end of the dropping resistor. Use insulating tape or shrinkable tubing to prevent the solder joint from inadvertently shorting to the chassis. Run these two wires along the bottom edge of the chassis to the lamp contacts on S1 and connect. Twisted extra pairs can be used to continue the lamp wiring in parallel. Solder all lamp connections. The power wires may now be laced or clamped from S1 to the terminal board if desired. If the previous instructions were followed the lamp wiring will not be laced or clamped with the audio cables and burned out lamps can be easily replaced.

DX WORD GAME

(see page 145)

Robert H. Nickel WA8OXS
21346 Pembroke Road
Detroit MI 48219

There are probably more DX countries in here — but these are all *we* could find.

When preparing the audio cables for connection to the transformer terminals, keep in mind that enough slack must be left to allow a hand and wrench to be inserted between the chassis and bottom cover to tighten the transformer clamp nuts to the screws which still will be inserted through the bottom cover. At least 1½ inches clearance should be allowed. After soldering the audio cables to the transformer, run a wire from the ground bus to the nearest leg of the transformer clamp. Solder one end to the ground bus and the other end to a solder lug large enough to fit the transformer clamp screw. Be sure that all terminals used as shield grounds on the transformer are also connected to this lug for grounding. A small bus wire will work well. Check J5 and turn if necessary to keep it from shorting to the transformer mounting clamp when the bottom cover is attached.

Operation

To use the phone patch, place the PTT microphone switch to Off. Dial the given number on the telephone. While explaining to the person on the other end of the line what is happening and why he must say "over," turn the audio gain on the receiver down to about one-fourth of normal and put S1 in Patch position. When you are ready to start, put S3 in Line position. The phone line is now connected to the audio distribution control, and throwing S2 to Aux/Patch will activate the transmitter. You may identify through the microphone of the telephone handset and monitor through the earpiece. The receiver audio gain should be set so that peaks are not above "0" on the VU meter. The transmitter audio should be set for a normal meter indication.

To use the audio distribution control unit as a station transmit/receive relay, as in RTTY or CW operation the PTT switch on the microphone should be Off and S2 moved to the Aux/Patch position. All other switches remain in their normal position. In those stations where VOX or break-in CW is desired, the relay in this unit may be used with your existing circuitry, with minor circuit changes in the relay connections.

With this new unit patching, audio anywhere necessary is a simple matter, and the relay offers versatility in controlling station functions.

ECONOMY VOLTAGE MULTIPLIER FOR SCOPE HV SUPPLIES

Smile when your power supply burns up and fills your shack with evil-smelling smoke.

The bulky and expensive high voltage transformers quite often used for scope power supplies are unnecessary and obsolete. Here is a modified voltage multiplier circuit that will replace them. It even uses fewer components than the standard voltage multipliers.

Recently my 20-year-old oscilloscope main power transformer developed an internal short and burned up. I was rather dismayed, as I had built several scopes myself and was quite familiar with the problems involved in the scope power supplies. The power supply was always the least enjoyable, most costly, and most frustrating part of the construction. In this

R1 – 1.5K
C1 – .25 μF, 1 kV
C2 – .5 μF, 1.5 kV
C3 – .25 μF, 1 kV

Fig. 1. Standard voltage doubler circuit.

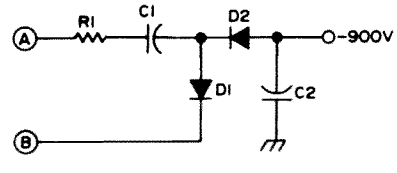

Fig. 2. Modified voltage multiplier. It is now operating as a voltage tripler. If T-1 had a higher rating, such as 375V, this circuit could well be adequate for most scopes.

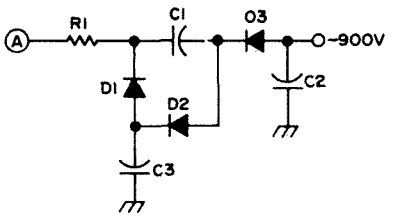

Fig. 3. Standard voltage tripler.

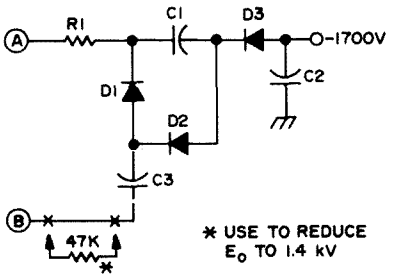

Fig. 4. Modified voltage multiplier. It now appears to operate as a voltage sextupler.

particular case, the possibility of directly replacing the transformer was not practical as it had a special winding to supply the HV to the scope rectifier along with the B+. This meant, of course, that two transformers would normally be required for replacement. With the current cost of transformers as high as it is, the repair prospect was quite gloomy.

I have built several special purpose RTTY oscilloscopes and have always found a considerable magnetic distortion problem to exist when they were completed. In all cases these problems were traced to the 1500V transformers used for the scope power, even though they were described as "shielded." To compound the problem, there is usually very little choice of alternate locations further away from the CRT for this transformer in most scope cabinets. Using CRT magnetic shields was never more than partially effective in these cases. Since these scopes were usually for a relatively non-demanding display, I usually just decided to live with the problem and ignore it. Unfortunately, this was my main development scope that had just quit, and I couldn't stand any magnetic distortion in its displays.

Since high voltage semiconductors are now readily available and quite inexpensive, I decided to go the voltage multiplier route for scope power. I installed a 300-0-300V power transformer to take care of the B+ requirement and started trying the voltage multiplier circuits.

The first circuit that I tried was a voltage doubler. It worked and provided 600V. The scope trace, on a 5BP1, could generously be described as feeble. For some reason I felt particularly inspired that day, so I tried an experiment. I lifted the grounded end of D-1 and connected it to the opposite side, point B, of the power transformer. Well! Three very interesting things happened:

(1) 900V was generated.
(2) The scope trace improved from feeble to mediocre.
(3) Smoke – the 600V capacitor, C-1, shorted.

I obtained some 1 kV capacitors and continued experimenting by going to a voltage tripler to see what it would do under similar conditions. The standard tripler gave 900V as was expected. I lifted the grounded end of C-3 and connected it to point B of the power transformer and:

(1) Pinned the needle on the 1.5 kV scale of the VTVM.
(2) The trace became bright and sharp.
(3) Smoke – all the 1 kV diodes shorted out.

The circuit was rebuilt and installed in the scope. I used 1 kV bathtub capacitors for C-2 and C-3 and two series connected diodes for D-1 – D-3. Shifting to my VOM which has a 2.5 kV scale, I found the output of the circuit to be approximately 1.7 kV. As my original filter capacitor, C-2, was only rated for 1.5 kV, I had to reduce this voltage in order to keep from overstressing it. This was done by putting a 47K resistor in the "B" leg of the multiplier. This brought the voltage down to about 1.4 kV.

I am not familiar with the analysis of this circuit, but I feel certain that someone will eventually supply a nice erudite complex analysis of it, as well as extending its application and modifying it for improved performance.

VFO OPERATION FOR THE TWO'er

This article may be of some interest to newcomers in the 2 meter band, or even some amateurs who might be tired of being rock-bound. Maybe you might want to check in on a club net, or break in on an interesting QSO. Vfo operation would be handy on Field Day, or to do a little DX chasing. If you were to buy half a dozen crystals or so, you would have spent enough money to build a good solid-state vfo or perhaps buy one cheap at a club auction.

For this article I used the equipment on hand, which was a Heath HG10 vfo and a Twoer (HW30). The receiver being what it is, there is a disadvantage not being able to spot the vfo frequency on the B-R-O-A-D regenerative receiver. There is a way to solve this broadness. If you haven't already converted your Twoer receiver, as described in an article titled "More Selectivity For The Twoer" in the June 1963, *73* I recommend the conversion. It is well worth your effort! It makes the receiver usable.

I might add that several members of the Hayward Radio Club, including myself, use Twoers on the club net, with the receivers converted as described in the article. We are very satisfied with the results.

The vfo coupling circuit description is simple and parts cost little or nothing. The HG10 vfo covers 80 through 2 meters and is a fairly stable vfo. The output circuit is a low Z cathode follower, with a common ground return. The Twoer uses a Pierce oscillator which does not have a common ground on the crystal oscillator.

This means that the vfo output cannot be directly coupled to the Pierce oscillator.

The vfo was link coupled to an 8 MHz series tuned tank for load isolation and impedance matching. I found it necessary to isolate the 8 MHz tank from the screen dc voltage in the Twoer. C1 of the 8 MHz tank is the dc blocking condenser. The 8 MHz tank was built on a crystal socket holder, so it could simply be plugged in and out.

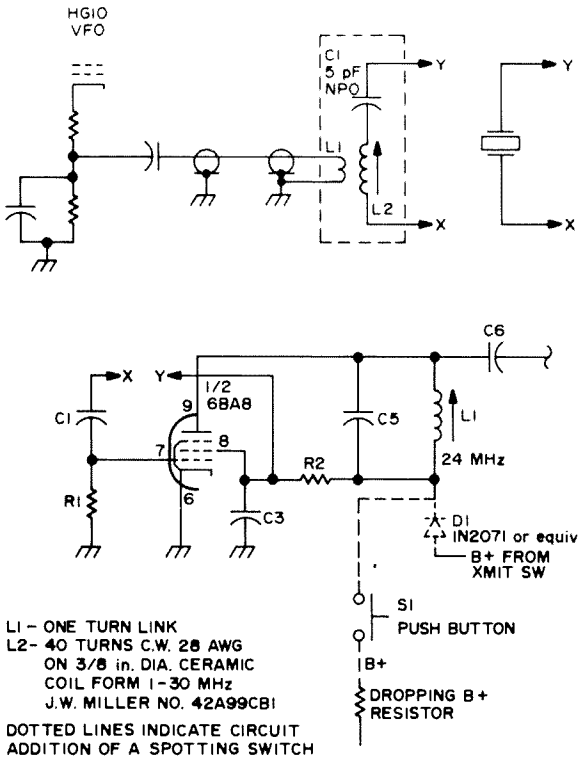
Perhaps you might want to make a more permanent setup and use a DPDT switch. One thing of importance is to make sure the one turn link is kept from moving once the tank is tuned. The 8 MHz tank is sharp and moving the link will cause detuning. Keep the link secured well.

Tune the 8 MHz tank for resonance in the middle of the band. The length of the output cable from the vfo will change C1 somewhat from the value shown.

The method used for spotting the vfo frequency on the receiver is to key the Twoer oscillator coil (L1) and the B+ bus from the transmit function switch. In the forward direction, the transmitter with the diode works normally. In the reverse direction, it keeps B+ from the rest of the transmitter circuit when the oscillator is keyed. I might add, other types of vfos could be used with the Twoer as long as the coupling circuit remains the same.

As a final comment, I also cannot see why the Sixer (HW29A) will not work with a vfo the same as the Twoer, since the circuit is basically the same.

. . .WB6FVW



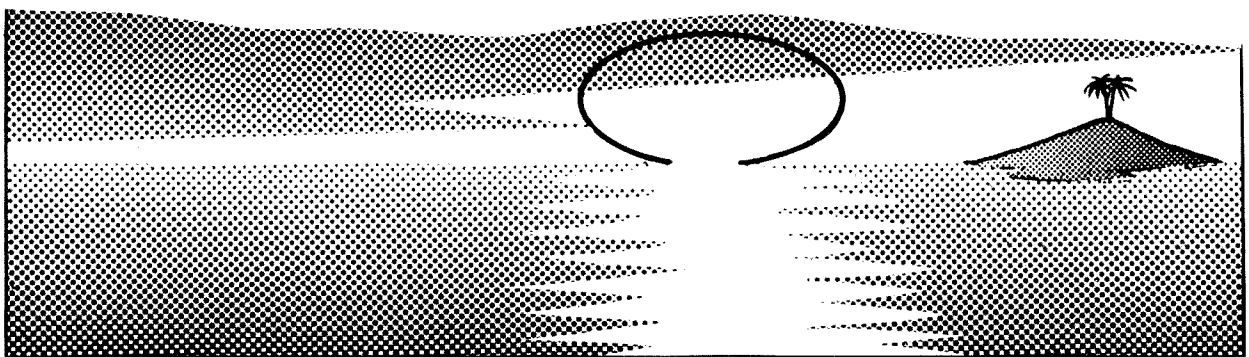


Fig. 1. MHz series tune tank.

ANNOUNCING THE 73 DX-PEDITION TO BAJO NUEVO HKØ

Join Wayne Green, W2NSD/1 and Keith Lamonica, W7DXX/1 as we operate from BAJO NUEVO. Picture yourself next November operating HKØDX from a tropical island in the Caribbean. We still have room for good operators. If you would like to be part of the 73 DX-pedition to BAJO NUEVO, Call Keith, W7DXX/1 at 603-924-3873 for details. HURRY!

35 Whynot St., West End 4101
Queensland, Australia

/MM MANEUVERS

I'll bet you have a secret desire. Every man has his unspoken yearnings, be they paranoic dreams or just wishful thoughts. We all want, at some time or another, to escape from this crazy, phoney rat race or from some personal predicament.

Well, my craving is simple and virtuous. I'd like to sail a small ship and of course equip it with a good ham rig and go /mm. I've never dug deeply into myself to find the real reason, but for years this longing has persisted; it's common enough to many men. Maybe my ancestors were seafaring folk or perhaps it's that eternal situation that man forever creates for himself – a challenge. So whenever the emotion takes me I simply vacate the office and drive down to the city docks and spend rapturous hours watching the small craft come and go. Some from just across the bay, others from across the world.

You might say – "So what? Such a desire should be easy enough to satisfy. Use your spare cash and buy a boat." Yes, but there's one snag; I'm absolutely the worst sailor in the world. The wash from a rowboat is enough to send me to the rail to throw up. I can, if the weather's perfect and I'm dosed with sea sickness tablets, take a trip across the Tasman in a ship about the size of the Queen Mary. However, come the slighest swell and I'm like the proverbial Albatross who as soon as it lands on a vessel is immediately disoriented.

In fact I've been the object of medical investigation and discussion over my problem. At the City Hospital a panel of doctors examined me closely. How can anyone so apparently healthy get so violently sick and go so jelly-like so quickly at sea? Eventually a diagnosis was made and given a medical name. (Don't ask me to spell it, I can't even pronounce it.)

"It's an undue sensitivity, like an allergy, to movement or motion of a certain rhythm. Just keep both feet firmly planted on terra firma," was the professional opinion.

Now what sort of useless advice is that? It's like telling a man with diabetes to eat no sugar. The craving remains, so does the illness – and grows worse.

One day at the office I was having a chat with a psychologist friend of mine, and I told him of my passion for small boats, but that I was an armchair sailor, as they did terrible things to my innards.

"Maybe, but a suppressed desire is bad. In fact," he said, "deny it long enough and you're psychosomatic."

"I'm what?"

"Sick in the head – and all over."

"Really!"

"Yeah. That's what's wrong with half of us. We're too inhibited."

Was he, in a kind way, pointing the finger at me? It seemed I had more than a desire: I had a problem. The conversation was getting

out of my depth, so I was about to change the subject, when he said: "Take my advice and gratify your urge, OB. Try a trip somewhere; a little motion sickness won't kill you."

"Wanna bet?" I said, trying to make light of it.

The phone rang. It was the YF, Helen. "Al, you haven't forgotten that auction sale?"

"Oh, the auction – no, not at all, Honey," I lied. My spirits weren't particularly up. I'd drawn a blank with my last dozen clients and that puts any real estate man down. Auction sales are another form of challenge, but oh no, not today. I wasn't in the mood to face the piles of junk, the stale and musty smells, the odd-bods and general confusion in a big, dirty hall. But the voice on the phone persisted. The YF was not to be put off. It would have been easier to stay the tide.

"Now remember, it's the Oriental five--piece period sun room suite, No. 377 in the catalogue."

"Our sun room's OK," I said hopefully. My rig was set up in a corner of it, and I had no wish to be demoted to the bone-chilling den downstairs. But the YF, determined to carry out her house-proud scheme to every room, had decided to 'restore' it. The renovations would no doubt be artistically done, but my comfort would go in the process.

"Clare Jones and her friend from down the street are going, so see you out-bid them"

So that was it.

"Why aren't you there now? We'll miss out."

"All right Honey, I'll go along and look it over." I replaced the phone; argument would have been useless. My psychologist friend had taken his leave. Outside, the bright sunshine warmed a crisp, clear morning. What the heck was I doing sitting in this dingy, unheated office trying to make a fast buck?"

Delegating the business, such as it was, to my typist for an hour or so, I picked up my hat and headed for the car. "To hell with the auction sale," I mused. "I'll say the bidding was too high." Ahead of me there appeared an expanse of blue water and a flotilla of ships. Stimulated by the tang of salty air I sauntered out along a broad jetty, its rough planking bleached white by sun and flying sand. Thirty or forty small boats, commercial and private, were tied up and in them zestful activity raged. Some of the fraternity were scraping, painting and renovating; others loading and unloading.

A wide variety of odors, colors and sounds assailed and quickened my senses. Two blocks away roared a car-crammed asphalt jungle; here was a new and stimulating horizon. Adventure called.

Every man, they say, has his susceptibilities. Today, the wide expanse of blue water seemed irresistible. The vitality and gaiety of those who live in small ships is alien to the average inhibited city dweller. For the passing hour, at least, the business rat race was unsupportable. Oh, just to get away from it all. Not far north were palm-studded tropic isles, golden sands and an eternally warm sun. I was really letting myself go, mentally.

The sound of loud profanities reached my ears. From the cabin of a commercial type 40 ft cruiser, a voice was raised in frustration.

"The blasted thing was serviced on the last trip. Are you sure it won't 'G'?"

"Yep, Skipper, it's dead as that crate of mullet, aft."

"We're supposed to sail on the turn of the tide. Try the sunofabitch again."

The ship's name, I noticed was "GIDUP'NGO," but something inside wouldn't. Two men were bent over the radio gear. Poking my face through the Bridge window, I said, "Can I help?"

"Er, yep. If yer a radio man, come aboard." A swarthy, mahogany-tanned little man, in a skipper's cap, eyed me, for the moment, suspiciously.

"I'm Al Shawsmith."

"The name's Burns, and this is my mate, Eddie.'

I explained my qualifications. The Skipper waved a hand toward the equipment.

"Take a look – and there's a box of spares if you need something."

The rig proved to be a modern powerful one, with several fixed frequencies as well as GP coverage; also, the ham bands were

clearly marked. A flick of the on/off switch showed the prior blasphemies were justified. A couple of bumps with the palm of the hand on the Genemotor, and it moaned sickly. Further inspection showed a suspect connection in the circuitry. Soon it was humming musically and very much alive.

"It really needs a test out in the bay," I shouted above the auto and local QRN.

"OK – will do," said the Skipper, looking pleased, and motioning Eddie to the mooring ropes. 'Come for a spin?"

Apprehensively I gazed at the restless mass of open blue water.

"I'm a very bad sailor – really bad –," I began.

"What! On a day like this? Why, there's hardly a white horse to be seen."

Yes, it did seem too good to miss: the advice of my medical friend was still fresh in mind. "Right," I said, "Let's go."

The speed of GIDUP'NGO surprised me. There was no wallowing. She rode smooth and fast. As expected, the gear tested one hundred percent on all frequencies. It sure was a natty piece of equipment, and I decided to case the ham bands; something might be audible and this was an opportunity too good to miss – reception being so much better at sea level. The only signal on 40 MHz was weak and unstable, but the call brought me to an instant alert.

"MAYDAY, MAYDAY, VK4 –– calling ––"

Could I believe my ears? Quickly I tuned the transmitter and replied on the frequency, with QRZ.

"Roger, Roger, Al, VK4SS. This is Harry VK4ZZZ. My car has crashed under Barron Bridge. Do you know my position – over?"

"Roger, VK4ZZZ. Your sigs are very weak, but I can copy. Yes, I know Barron Bridge. Are you injured – over?"

"Yes, my leg is jammed under the motor bulkhead. The transmitter power is failing and water is entering the floor – the tide. Please help urgently!"

The voice was strained with pain and shock. Skip Burns appeared at my side. "Was that a distress call?"

"Yes, a chap – a ham like myself – says he's under the Barron Bridge, in the river, and trapped in his car. He's hurt and the water is . . ."

"Yeah, the tide is on the turn. Hmmm, that's a colossal drop; must be eighty feet or more. Why hasn't someone seen him?" He paused and engaged me with direct questioning eyes. "Could be phoney, huh? Check it out; call him again and see how long he's been there."

"VK4ZZZ de VK4SS. Harry, do you read? Please say when accident occured?"

"About two hours ago I guess. Didn't smash through bridge but was side-swiped by some speed maniac; missed viaduct approach and rolled down steep bank into thick scrub and mangroves. Guess no one can see me from above. Have been calling into this transceiver for nearly an hour. Can't see the mobile whip at rear. Think it's broken or maybe this deep gorge is blanketing the sigs. Was about to throw in the towel when I heard your QRZ. For God's sake get help if you can. Are you out at sea or in the vicinity? I seem to be OK except for my jammed foot . . ."

The signal disappeared into the hash. Mr. Burns gazed at the stippled haze of a mountain spur across many miles of open blue water. "Whaddya reckon." he queried.

"Well I'd say he was a ham right enough, but . . ."

"Anyway, we'll have to report it, no matter who he is. Tell him help is on the way."

"VK4ZZZ de VK4SS. Roger, Harry, we are in the area and will contact land base for immediate help. Please QSL?"

No reply, so I tried again, but only QRN crackled in the confined space of the cabin. I switched to crystal control and the shore base frequency and QSP'd the details of the situation and the message received. I turned to the Skipper for further orders. His steady gaze still searched the horizon. "How far is the Barron Bridge from the city – by road? What time would it take by car to rescue––?"

"About three hours on the mountainous strip; that is, if they don't waste time with red tape. It's nearly a hundred miles from town and I can't recollect any nearby service station either."

Mr. Burns remained silent, evaluating the situation. Finally he said, "We can cut an

hour off that time. Anyway I couldn't let any poor bastard drown like that. Eddie, unlash the dinghy, stow it with rescue gear and make it ready for launching." The mate moved with sudden alacrity.

Long since have I been humbled by the whimsies of Fate. The circumstances of any life can change dramatically at any moment. An instant ago this was a pleasurable jaunt; now we were on a desperate dash to save a man's life. GIDUP'NGO was picking up speed and as we neared the open water I contemplated the crashing surf with abject horror. I had been through this before and knew of the consequences. "Oh for terra firma," I said to myself, and then felt guilty at the thought. Right now the rat race seemed less repulsive and the challenge of going to sea in small ships, much less romantic. All that was left was to put on a brave front. Already the landscape was beginning to spin and nausea cramped my midriff. I turned the receiver up in case VK4ZZZ should call again, and fell prone on the nearest bunk. Here the mate found me. "Hey, what's up?" he queried.

"Just queasy, I guess." How could I explain to a man of the sea my 'thing' about motion sickness.

He stood over me, his face a mixture of incredulity, pity and curiosity. "But we haven't hit the rough stuff, yet," he said. I must have looked bad, because he disappeared for a moment, and returned with a brown paper bag, which, of all odours, smelt of dead fish. Suddenly the boat began to pitch and roll, spray and blue water thudded against the porthole. The little ship fell into a trough between two rearing Pacific rollers, and at the same time, the bottom dropped right out of my stomach. I turned my face to the wall.

After what seemed an eternity, the drive of the power engine ceased, and GIDUP'NGO settled, and began to wallow. For some time, the ever-increasing sound of intermittent gunfire had been audible above the roar of the wind and sea, but I was too ill to question it. Now, sensing action was at hand, I struggled up from under a blanket of sea-sickness, and stood propped alongside the Captain at the wheel.

"Was that gunfire?" I asked.

"It was, and we have a problem. The Barron River forms one boundary of a restricted military area. The Army carries out manouevers here, from time to time. The rookies learn how to handle twenty-five pounders and other heavy stuff. All ships get prior notice. I should have remembered, but we don't have to actually enter the zone, only skirt it. If they keep to their range, we're safe."

"Could we call land base and request help from the Army," I suggested.

'Yep," the Skipper glanced at his watch. "It crossed my mind, too, but time is dead against it. We're behind schedule as it is."

GIDUP'NGO nosed slowly toward the river bar. The little craft rose and fell alarmingly in the steep and heavy sea. My mouth was hot and dry; also I had lost control over my knees and remained upright only because there was a stanchion handy for support. I realized that our moment of truth was at hand. Would she clear the bar? At that instant the sound of gunfire broke out again; so close now it percussed our ears. Shells struck the water with a whine and crump.

"Ignore it," commanded Mr. Burns, his eyes glued directly ahead. "We're still outside the official area." Like a plane at unstick speed we were now committed past the point of no return to negotiate the narrow channel. Suddenly there were two grinding and shuddering bumps.

"She's aground," yelled the mate. But GIDUP'NGO rose manfully again, backing up the next roller almost on her bowsprit. Then the deck seemed to explode under me and I was flat on my back in the scupper with the mate bellowing, "Skip, we've been hit. Holed in the port bow by those crazy bastards!"

At this point the world and I began to part company. Vaguely I remember something being dragged over my head – a Mae West. I was either dumped or fell into the dinghy; an oar was thrust in my hands and Mr. Burns was bawling, "Pull, for Christ's sake – ROW!" I made one desperate effort to obey before final oblivion brought blessed release.

. . . . . .

Consciousness returned rapidly (so I was told) as soon as they got me onto dry land. I had lain prone for over an hour, like a beached dugong in the bilge wash of the little dinghy while the Skipper and his mate strove valiantly to prise Harry from the crushed car. Suddenly the world around me reappeared as if from nowhere; there was a bedlam of noise, people shouting, car motors being started and the crunching of feet. The moment was the sweetest of my life; or so it seemed. No movement; I was lying on a stretcher on solid earth. The voice of Skip Burns was giving details to someone. "The other bloke's OK, just a busted ankle – lucky, huh. We're gonna take a lottery ticket on it, but this chap, well, I dunno. He just came along for the ride, to test the radio gear, but he's got a thing' about the sea, and passed out." Someone undid my soaked shirt and something cold was pressed against my chest; a stethescope.

"I'm OK, Doc," I mumbled.

"Yes, but you'd better go to hospital to see why you collapsed––"

A surge of irritation and shame passed through me, at my poor showing. "No," I said, a trifle piqued. "I'm going nowhere but home – but home."

"If you wish it, but I advise you to rest. You're still showing signs of stress." The doctor signaled the ambulance man.

On the trip back to town, the moments of truth, born in the crises when GIDUP'NGO was headed for Davey Jones' Locker, had time to sink in. My passion for life on the ocean wave and going /mm had vanished; it was useless pursuing the impossible. In a way I was grateful to my psychologist friend, whose advice had been to give it a go, and find out. To come to terms with one's self, is to be at peace. I'd be happily content in the shack from now on, even if I had to move it downstairs.

The ambulance drew to a halt. We were home, but my arrival was badly timed, to say the least. Two doors away, at the Joneses, a van was unloading the suite I was supposed to snap up at the morning's sales. The YF had been phoned so she was waiting – but HOW was she waiting. Human-like, I could have used a little sympathy or

congratulations over the past happenings. But she stood like an untamed shrew at the head of the stairs, and who can be angrier than a jealous, deceived woman? Before I could open my mouth, she pitched right in.

"Yes, I know all about it. You sneak off to sea when you're supposed to stay put: what a drag you must have been. For one who can't even watch The Cruel Sea on TV without being sick, I must say you're game – or stupid."

How much does a man stand! It was time for my anger. "Look," I said, "quit raving. You're bugged because you lost out on a little odious game of oneupsmanship with the Joneses. My seamanship's got nothing to do with it. We all might have drowned, but all you can think of is your house-proud status. The sun room stays as is, with the rig in it." Feeling I had said enough I made for the bathroom to change and clean up. As I peeled off the wet duds a QSL card fell to the floor. It was Harry's, and on the back was scribbled "Salesman for contemporary and period furniture." Someone must have slipped it into my pocket while I was 'out.' So that was his line of business.

. . . . . .

Helen and I were dressing for a party; a special occasion. Six weeks had now passed since that fateful day. I say fateful, because Lady Luck seemed to have smiled on everyone as a consequence of the rescue.

The impasse between the YF and me over my use of the cosiest room in the house as a shack had been unexpectedly resolved. Harry phoned with a plea, that he be allowed to make me a little gift of some sort: or, was there something Helen could use in the home. What transpired between them, I'll never know, but I'm sure my ham friend is a diplomat as well as a furniture salesman. Yards of lush, rich drapes and carpets arrived for bedrooms and lounge. This was his "little" gift, and it set the YF to redecorating. The sun room was forgotten, and I was left in peace.

Harry presented me with his old mobile rig which worked perfectly, in spite of its dunking. His business firm had given him a new car, complete with a new rig, and to add to the lucky turn of events, between us we had landed a share prize in the city lottery.

Now here we were at an on-board, or ship-warming party to christen GIDUP'NGO 2. The sleek new 55 footer was a blaze of lights, and the small ships' fraternity was there in force. Skip Burns, a bottle of champagne in hand, and looking keen to pour the contents over someone at the first excuse, exchanged banter with all and sundry. Eddie, the mate, already three sheets to the wind, pitched and yawed among the guests; his duty, to keep the glasses full, including his own. Even landlubber Harry VK4ZZZ was there, showing off his plastered leg, and telling an audience how he was gargling the Pacific by the time Mr. Burns 'sprung' him from the car. Cuban Rum punch in hand, he kept the pace with the best of them, getting as high as the mainmast as he told of his lottery win with the Skipper.

A voice broke through the hubbub and salty slang – "Hey Burns, where didya pick up this pretty little packet? Piracy outside the 12 mile limit, or have ya got into the contraband racket?"

"Neither, Bud," The Skipper waved a sheaf of newspaper cuttings. "Haven't ya read all about it? The Army came good with compensation; collected some insurance, too. Then I raised the wind at the bank and Harry, Al and I had a win in the lottery. You'd heardly believe it, would ya?' He waved an arm around at the plush fittings – "So I bought GIDUP'NGO 2, all rigged, furnished, and set for deep sea fishing parties. Got it made, Eddie and me."

Someone suggested a spin. The mate unsteadily prepared to cast off. Those ropes were my umbilical cords to safety – land. I felt a trauma coming on, so it was time to leave. With good luck wishes all around, we waved good night. I knew the friendships made would remain.

Back at the car the YF said casually, "In a hurry to go home?"

"Not really. Why?"

"There s a real super study desk that would just suit the shack. It's on display downtown."

I smiled into the darkness. So the sun room was now my shack. My stint in the dog box was over.

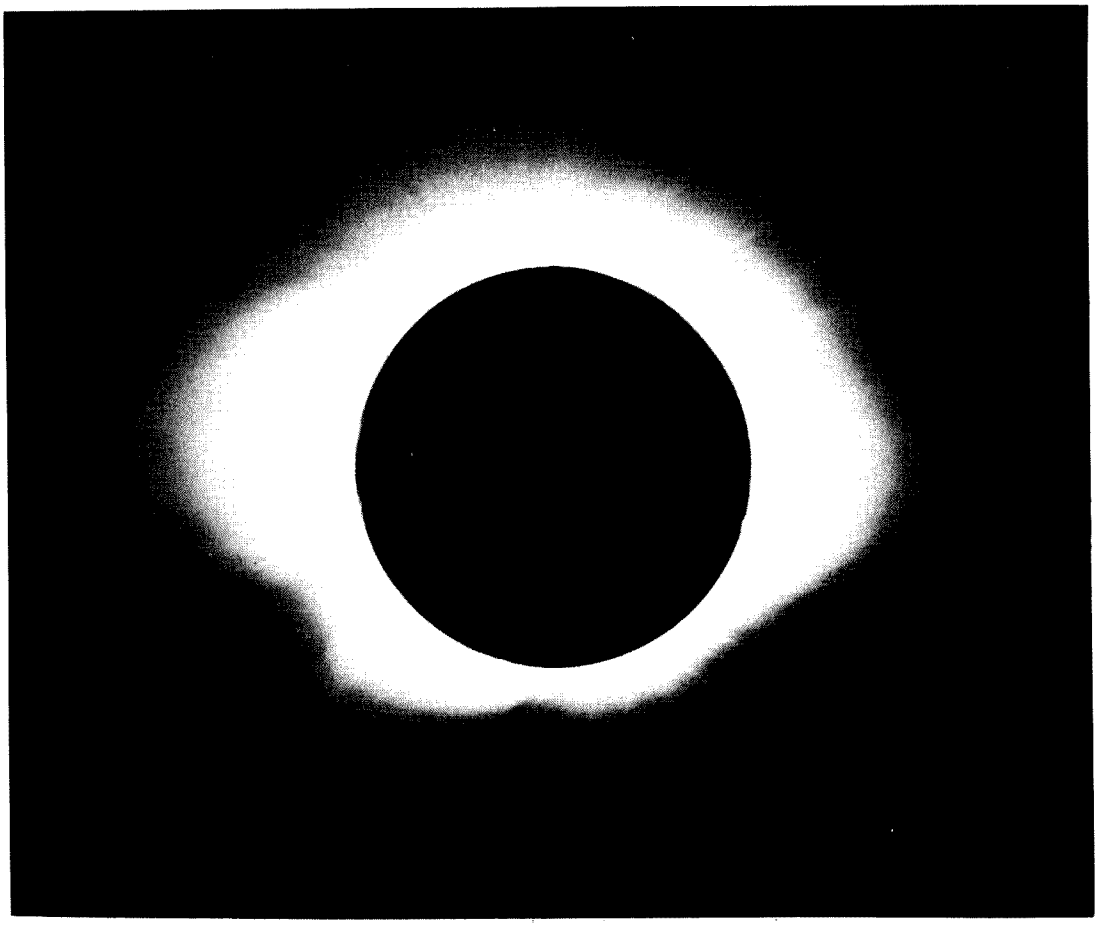
The SUN and RADIO



Prominences at the solar limb taken during the total eclipse of Aug. 31, 1932. The black sphere is the moon and the irregularities of the moon's surface can be seen in the photograph. Solar prominences usually occur in areas of high sunspot concentrations and between intense magnetic poles. (Lick Observatory photo.)

Such a statement may seem strange, but as we shall see the sun itself is one of the most important factors in radio communications from several aspects. The sun is a powerful radio transmitter, the cause of the ionosphere, source of magnetic storms and in general the most important factor to radio propagation.

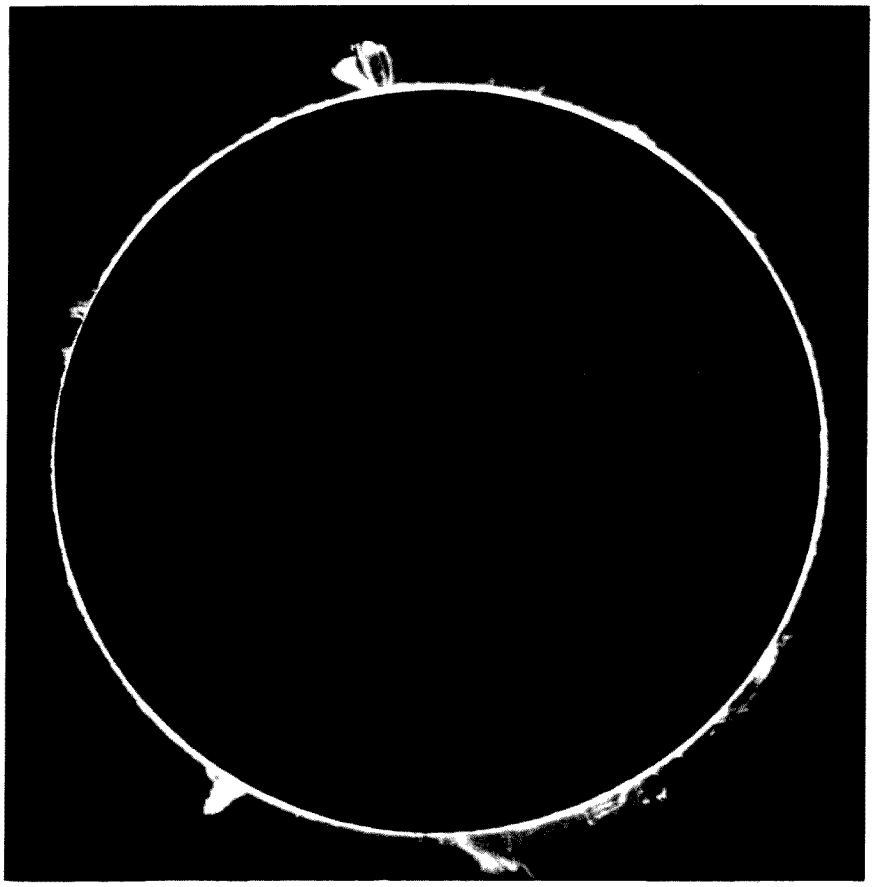
Without the sun no ionosphere would exist and DX on 20 meters would be only slightly greater than that of VHF. As a source of radio noise the sun aids radio astronomers to understand the mechanics of the solar sphere. Whenever solar magnetic storms occur not only radio but landline telephone and telegraph communications are interrupted. The sun is the cause of charged particles being spewed out into space sometimes causing the aurora, an excellent source of VHF radio propagation.

The Sun Itself

Our sun is a very ordinary middle-aged star. But to us it isn't so ordinary. It

The outer corona at the time of a total eclipse on Aug. 31, 1932 in Fryeburg, Maine. Without an eclipse or special instruments, the corona is not seen because of the bright light from the photosphere. The shape of the corona changes with the number and position of sunspots. (Lick Observatory photo.)

radiates some 5 billion horsepower per square mile on the earth and would take 100 earths placed side by side to make up its diameter.



If an observer in a neighbor galaxy were to look in the direction of our Milky Way all he would see would be millions of tiny specks of light, each one a separate sun. Among the specks would be one indistinguishable from all the others – our sun. Possibly, if viewed from another galaxy, our solar sphere and its nearest neighbor star group Alpha Centauri would not be distinguishable as separate objects they would appear so close. However, to give an illustration how far away Alpha Centauri really is, let us imagine that the earth and sun in a model are one foot apart. At this scale, the nearest star would be *fifty miles* away. The human mind can only quiver at the thought of such vastness.

This tiny speck in the universe is in reality 865,000 miles across and 93,000,000 miles removed from the earth.

When we observe the sun, we see a large yellow disk (and we never observe the sun with the naked eye or a telescope not equipped with a good solar filter), called the *photosphere.* The photosphere is the visible portion of the sun. It appears solid but in reality is gaseous like the rest of the sun. The photosphere has a temperature of 7,600 to 11,700°F.

Above the photosphere is the *chromosphere.* This layer, some 1000-2000 miles thick, reaches a temperature 20 times hotter than the surface. Normally the chromosphere cannot be seen because of the bright light coming from the photosphere. However, during eclipses of the sun and with special instruments the chromosphere may be observed.

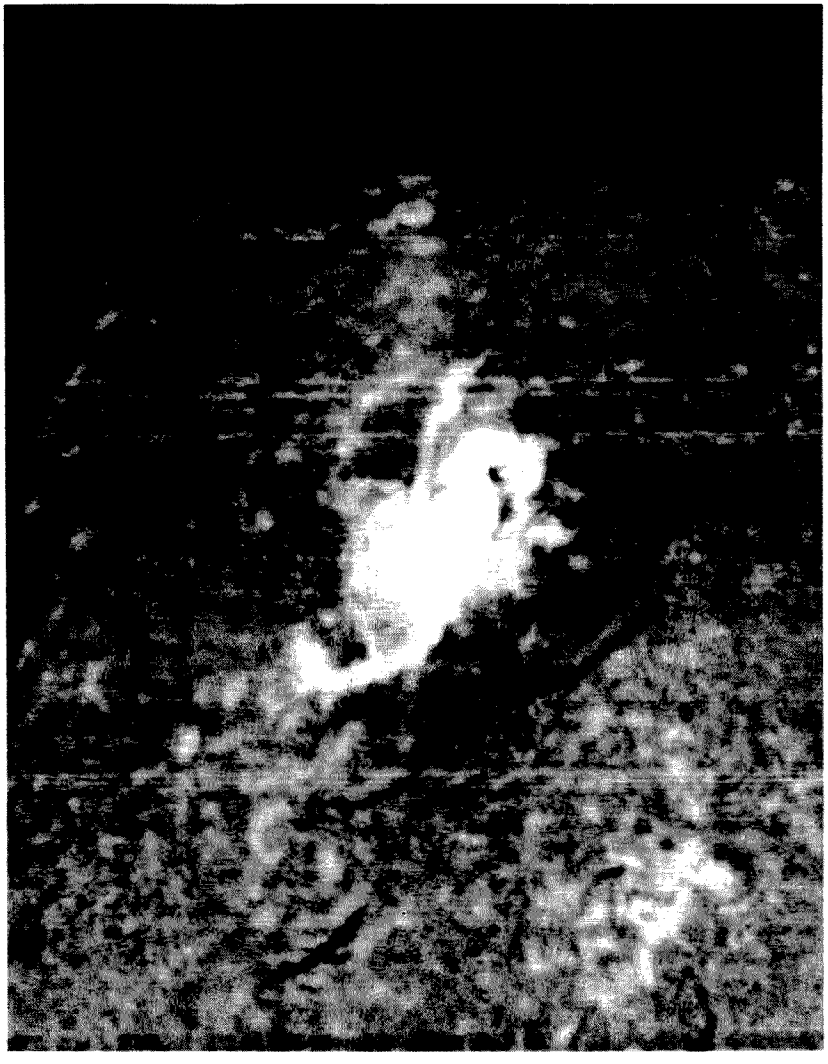
An interesting note is that in 1895 helium was discovered in the chromosphere of the sun before the element was found on earth.

Prominences. Whole edge of sun taken with calcium K line, December 9, 1929. (Mount Wilson and Palomar Observatories.)

Later we shall delve deeper into the chromosphere because this layer has a tremendous effect on radio conditions at the earth.

American astronomers Harkness and Young first discovered the corona (which extends above the chromosphere) during an eclipse in 1869. This layer reaches outward several million miles above the photosphere, and sears at a temperature of one million degrees.

Where does the sun gain all its energy? Over the past 150 years numerous theories have been expounded stating that the sun's energy comes from combustion, electrical process, and gravitational contraction. None have proved satisfactory. During the last 50 years the nuclear fusion theory has become the standard explanation for solar energy.



Energy comes from the fusing of four hydrogen atoms into two helium atoms. During the process two helium atoms weigh less than four hydrogen atoms. This extra mass is transformed into energy according to the famous equation derived by Albert Einstein and known to every junior high school science student: Energy is equal to the mass times the square of the velocity of light.

Naturally this process needs very special conditions to occur. The temperature must be at least 20 million degrees and the elements carbon and nitrogen are involved in the reactions.

Each star has a lifespan; like people, plants, and everything else, stars are born, grow, experience a middle age, grow old, and die. Each stage in the life of a star has its own special characteristics.

A star starts out as a large mass of hydrogen gas, very low in density but spread over an area about three lightyears across. Local concentrations or clumps of hydrogen form and, if the concentration is large enough, more and more hydrogen is attracted to these clumps by gravity.

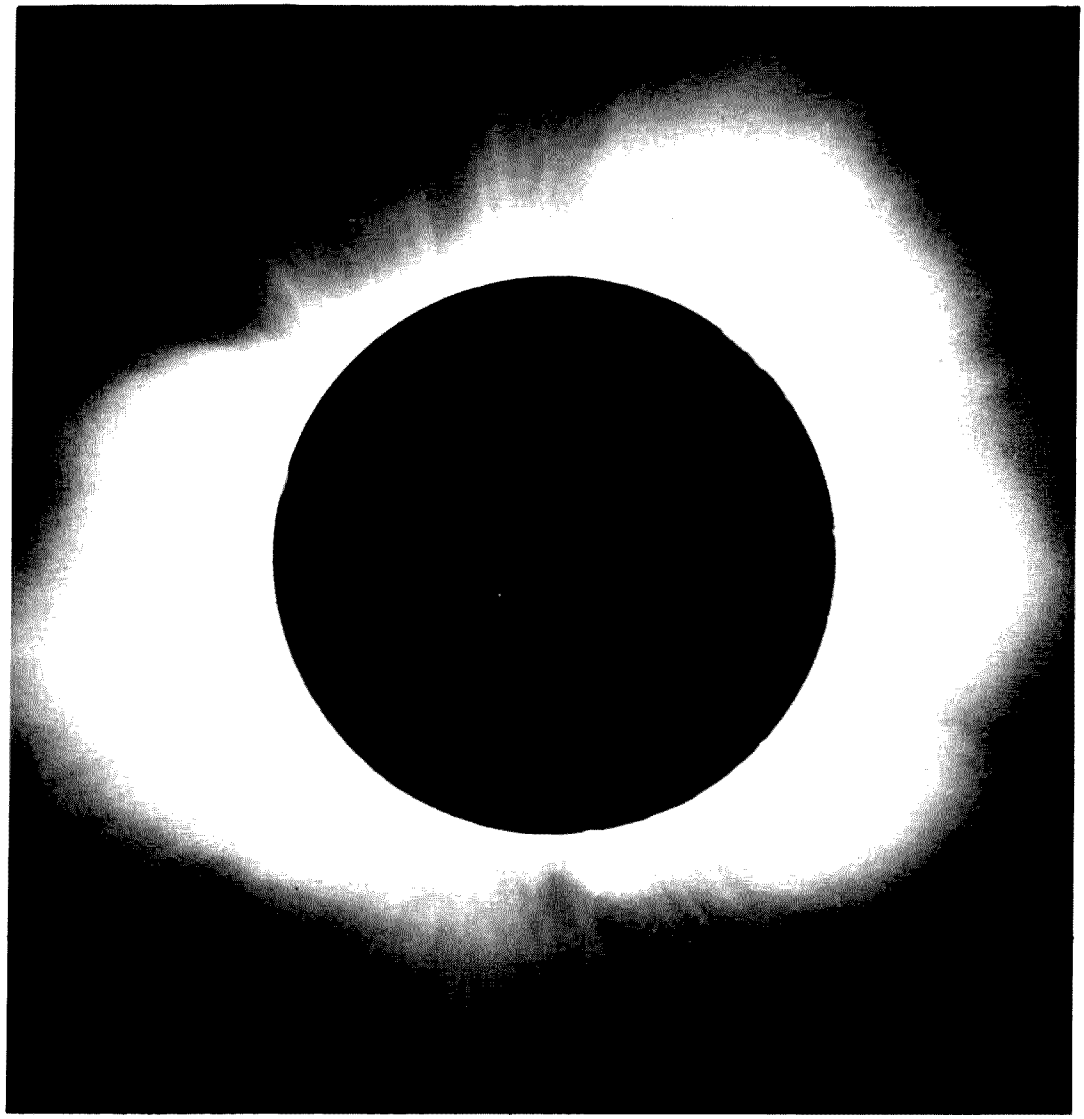
This new star, termed a red giant, is relatively cold and gives off a reddish color. The pressure of the star's material clump-

SOLAR FLARE photographed in red light of the hydrogen a line. 1959 July 16. (Mount Wilson and Palomar Observatories.)

ing together causes the surface temperature to rise to about 1000°F. At the core the temperature might be a million degrees. The process is similar to a bicycle tire pump. When the air pressure in the pump's tube is increased by pressing the plunger, the temperature inside the tube becomes hotter.

After the star has been well formed, the temperature keeps rising. At birth the main source of energy was gravity, but then the temperature increases to the verge of nuclear reaction. This alternating between sources of energy is thought to cause the variability in brightness observed in some stars.

When the temperature reaches 20 million degrees, most of the star's energy comes from nuclear reactions. This is a fully grown star and where our own sun is now in its lifespan.



As the sun becomes older, it will become hotter and more luminous, until in a few billion years the earth will experience a temperature far greater than that at which life could exist. The oceans, rivers, lakes, and ice caps will boil away leaving only a scorched rock oribiting the sun.

After the sun's day of glory, it will become fainter and much smaller. It will be known as a "white dwarf" – very hot and very dense.

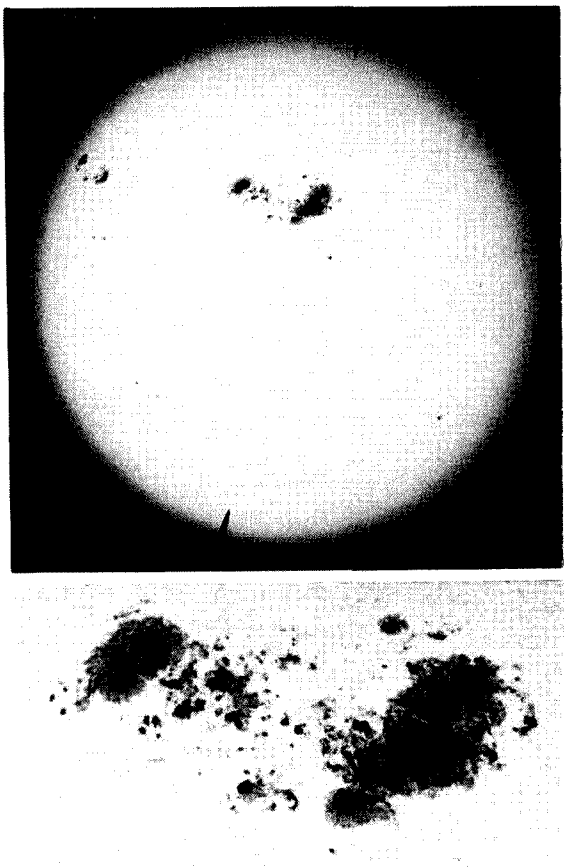
Finally the solar furnace will fade away, leaving the planets circling a cold, dark mass and the sky in that celestial vicinity will be as black as a moonless night forever.

The Sun and Radio Communications on Earth

The ionosphere exists because of the action of ultraviolet energy from the sun on the oxygen and nitrogen atoms in the upper atmosphere. The ultraviolet energy

Solar corona photographed at the total eclipse of June 8, 1918, Green River, Wyoming. (Mount Wilson and Palomar Observatories.)

frees the electrons from some atoms, causing a layer of ionized atoms and charged particles.



The ionosphere will reflect radio signals if only the right amount of ionization occurs. If the sun releases too much ultraviolet energy the ionosphere will have too many ions. When this happens our shortwave signal is exhausted in the interaction with large numbers of the charged particles.

The ionosphere is divided into several layers, the lowest of which is termed the *E layer*. The E layer forms at the maximum of 70 miles. At 70 miles the air is so dense that free electrons have only to move a short distance to recombine with another atom. Because of this ultraviolet energy must be present at all times to form the E layer. This means that the layer forms only during daylight with the highest concentration of ionization at noon.

During daylight hours, the *D layer* forms below the E layer. The D layer exists only during daylight and tends to absorb the daylight 80 and 40 meter signals. This is the reason distances on 80 and 40 meters are much less during the daytime hours.

The highest layer is the *F layer*, at an average of 175 miles. The air at this altitude is so thin that ions recombine slowly. At night, the ionization level slowly decreases, reaching minimum about 4 a.m. At night the F layer is one layer, however, in the daytime the F layer breaks into two parts (F1 and F2). The F1 is at a height of about 140 miles and the F2 is at 200 miles.

Sporadic E is another part of the iono-

sphere story. Sporadic E patches occur as dense clouds at approximately the same altitude as the E layer. These clouds may occur at most irregular intervals.

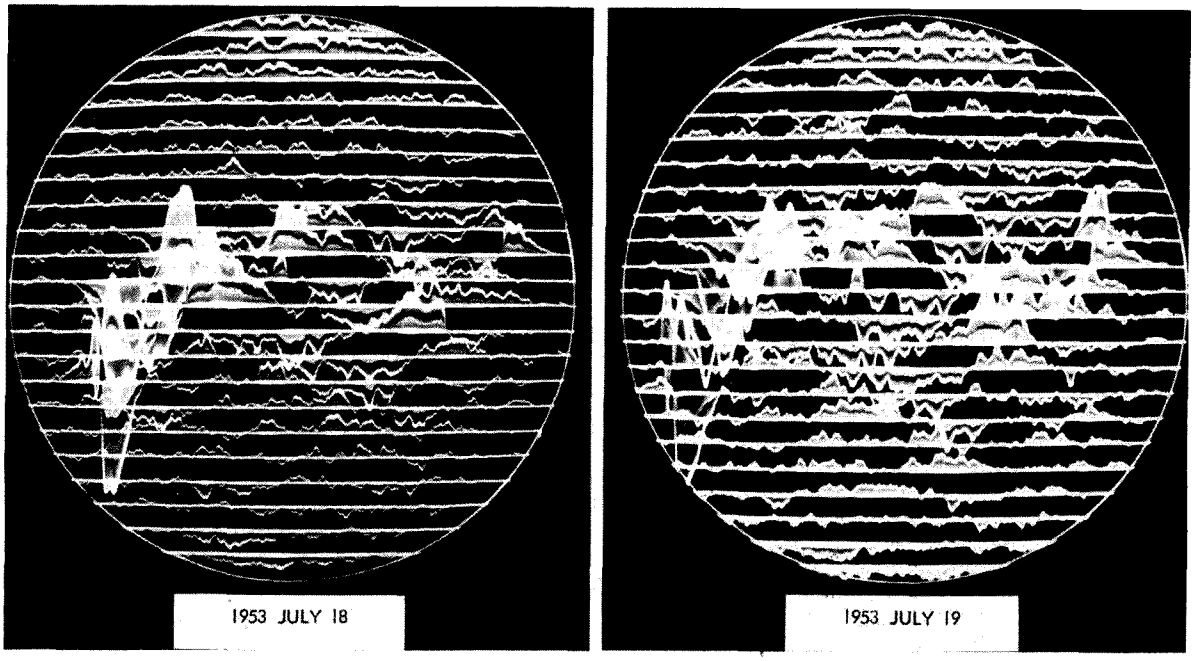
All of these layers of the ionosphere occur because of ultraviolet energy from the sun. During times of solar disturbances, sunspots, solar flares, and solar prominences the level of ionization tends to increase.

Heinrich Schwabe, a German businessman and amateur astronomer, in 1843 published his conclusion that sunspots tend to follow an 11-year cycle. Sunspots had been known for over 200 years since Galileo had first noticed their existence. Schwabe, however, first noticed the sunspot cycle.

At various times correlations have been attempted between sunspots and a variety of happenings on earth, from the price of wheat to the average jumping distance of the Australian kangaroo.

However, the sunspot *cycle* does have a definite effect on radio communications. During periods of maximum sunspots, the lowest frequency that an ionospheric layer will reflect is increased. Conversely, the frequency is lowered during minimum sunspots.

There has been a correlation between the number of sunspots and magnetic storms which disrupt the earth's magnetic field. Magnetic storms are most likely when large spots are near the sun's equator and last up to 4 days even after the spots have disappeared.



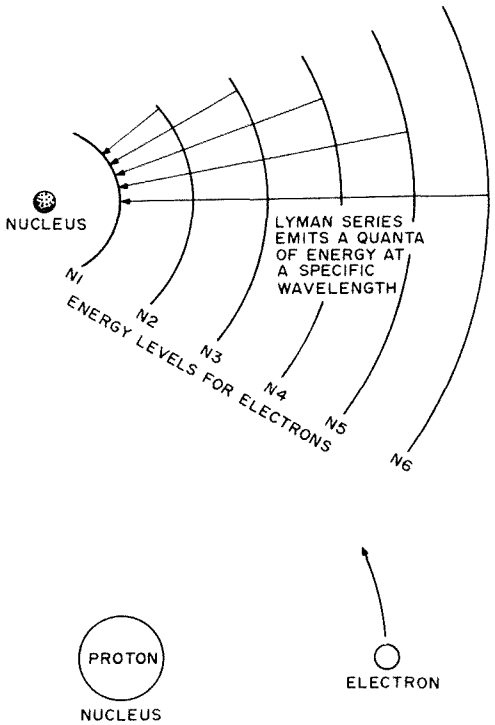
Sunspots cannot always be relied on for predicting magnetic storms. On November 13–14 1894 a large magnetic storm occurred but not a single sunspot was observed. Just the opposite occurred on December 17–20 1946 when no magnetic storm occurred but several huge sunspots moved into the right area of the sun to cause storms.

Sunspots exhibit one of the most powerful magnetic fields in the solar system. When a pair of spots appear a very strong polarity is set up. This field is much greater than anything maintained on earth and several times stronger than the sun's normal magnetic field. The sunspot itself is a mystery 350 years after Galileo's first observation. We know that the sunspot is actually an area that is about 3000°F cooler than the surrounding photosphere, but exactly why sunspots exist we do not know.

The sunspot only appears dark because it is cool in contrast to the hotter photosphere, however, if the sunspot were removed from the surface and put into space it would shine rather than appear black.

Sunspots occur at different positions on the sun during the cycle. During the beginning of a new cycle, most spots occur about 30 degrees north and south latitude on the sun's surface. Toward the end of the cycle most spots have come down to about 15 degrees of the equator. The last group of spots usually turn up at less than 10 degrees in latitude from the equator.

An interesting fact has arisen about the sun from the study of sunspots. The sun being gaseous doesn't revolve at the same rate on each latitutde.



Emission of Ultraviolet Energy

Of great important in radio communications on earth is the emission of ultraviolet energy from the sun. Increases in ultraviolet emission occur at various times usually asssociated with large sunspots and solar flares and can cause communications difficulty. However, a constant level of ultraviolet radiation is needed to maintain the ionosphere.

Let us find out why the sun emits this ultraviolet energy.

The arrangement of hydrogen particles – one electron circling a nucleus – was first described by the Danish physicist Niels Bohr. Bohr's atom has since proved to be inaccurate, though we can use his familiar description of the atom as the nucleus being similar to the sun with the electrons being the planets.

Electrons do not always stay in the same orbit. For hydrogen, there are seven orbits, or "energy levels," in which the electron may be at any given time. Each

time an electron changes orbits a quanta of energy is either released or absorbed. If the electron falls to a lower orbit, energy is released; however, if the electron jumps to a higher orbit, energy of a specific wave-

length of energy is absorbed by the process.

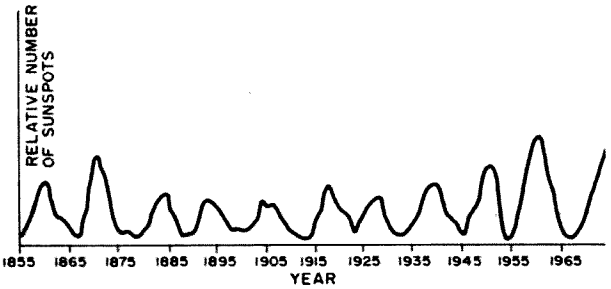
One of these jumps is termed the *Lyman Series*. Only about one atom in a million in the solar atmosphere is excited to this state. However, this is enough to emit energy in the ultraviolet portion of the electromagnetic spectrum.

Along with sunspot cycles, solar prominences and solar flares influence terrestrial radio communication.

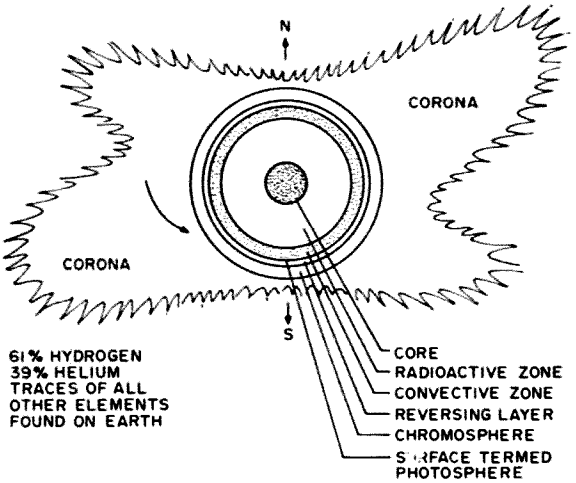
When a solar flare occurs, great quantities of ultraviolet energy are ejected into space. This causes radio signals to be absorbed or reflected erratically, destroying reliable communications.

During disturbances of the sun's surface, charged particles are often spread forth. These particles, upon reaching the earth, are channeled by the earth's magnetic field to one pole or the other, depending on the polarity of the pole and particle – thus producing the "aurora."

Every good VHF man knows that the aurora can be used for radio propagation just by pointing the antenna at the "curtain." However, good auroras tend to occur about two years after the sunspot maximum. Why? We don't know. Nobody does!



The Sun as a Radio Source



Radio waves make up a small part of the electromagnetic spectrum. The spectrum consits of radio waves, infrared, visibile light, ultraviolet, X-rays, and gamma rays. There is no distinct boundary between these forms; each fades from one form to the next.

The sun radiates all forms of energy along the electromagnetic spectrum. However, the sun itself – along with the earth's atmosphere and ionosphere – filter out most of the energy.

The quiet or undisturbed sun radiates with a constant signal level over several frequencies, originating from the chromosphere at temperatures between 10,000 and 40,000°K. Thermal stimulation of charged particles cause this radio radiation.

In the corona – several million degrees and several million miles out from the surface – is a strong source of radio radiation. This is one reason why the radio astronomer says that the "radio" sun is several times the "optical" sun in width.

The optical sun is very stable. We know this simply by observation. The sun doesn't appear to change in size or shape but the radio sun varies widely in size, shape, and intensity.

When the sun is disturbed, radio noise increases in signal level by a fantastic amount. At times, increases of a millionfold have been recorded. Radio noise seems to increase with solar surface phenomena such as flares, prominences, or sunspots. When large sunspots appear, radio noise can be detected several days before the spot appears and several days after the spot has disappeared.

We often take the sun for granted, little realizing that it is the master of our solar system. It is so massive that it makes our small planet look microscopic. Yet compared with the universe, the sun is so small that the English language has no words to express its small size. Truly, its proportions defy description, be they considered relatively as massive or minuscule. Yet none could deny the gargantuan effect of our tiny giant on earthly communications.

POOR MAN'S TRANSCANNER

Being an active FM'er, already the proud owner of a Regency HR-2 that was chock full of crystals, you might say I felt as though I were in FM heaven. And I was, until that day in September when I spotted the new Regency Transcanner at the Cincy stagfest. Wow, what a rig! With all the frequencies in use back home, I could sure put one of those to work. Hardly a day goes by that I don't miss a call or two, just because I m listening to the wrong frequency.

Like the rest of you probably, I sure didn't have the $300+ necessary to buy such a rig. What was worse, I couldn't even find anyone who would make a decent offer for my HR-2. It seems at a hamfest everyone wants something for nothing. Anyway, I spent the fifty hard-earned bucks I had with me for some useless knickknacks and left for home.

A few months later, still dreaming of the "super-rig," a friend of mine came to the house to show me his latest plaything. A Regency TMR-8H high band scanner. I thought to myself, "Now isn't this just what this knothead needs – a super-glorified, light-flashing, CB'er's delight fuzz monitor." It wasn't until some time after he left that I started thinking, "Wonder if one of those would work on two meters?"

The next evening after work I dashed to the local CB establishment and asked the guy at the counter to "Lemmesee one-a those' instruction books for one-a dem scanners." The fellow was a little apprehensive at first, but I managed to get it across to him that I had a particular idea in mind, and I wanted to see if this gadget would work. He consented. My hopes were well-founded. The Regency TMR-8H *would* work – perfectly. I handed the guy a check

for the purchase price (slightly greater than one-third the cost of the "super rig" I had dreamed about) and headed for home.

Inside the house I declared the kitchen table a disaster area and scooted the XYL into the boob-tube room. Next came the scrounging of tools and leftover parts from past projects. I took a seat amidst the chaos.

I hurriedly removed the cabinets from both rigs, and began transferring the receive crystals from my HR-2 over to my new Scanner. Then the big moment – the little telescoping antenna in place, the ac cord plugged in, and the power on. IT WORKS! That's Doc working Woody through the seven-six machine twenty miles from here. Not bad!

The sensitivity needed a little improvement though. I instructed the XYL to touch nothing on the table and headed for the local Motorola repair shop. The fellow there is a ham, too, so a quick realignment of a couple of front-end slugs was obtained easily enough. "Gee, sure was way off," I said meekly. "Let's see how the thing checks out now . . . not bad. An easy 0.3 μV for a good 20 dB of quieting. See you later, and thanks!"

The next step was to provide for muting and antenna changeover. No problem at all. The HR-2 antenna lead is already switched by the T/R relay, and looky there . . . an extra set of SPDT contacts that will handle the muting job perfectly. This must really be my day.

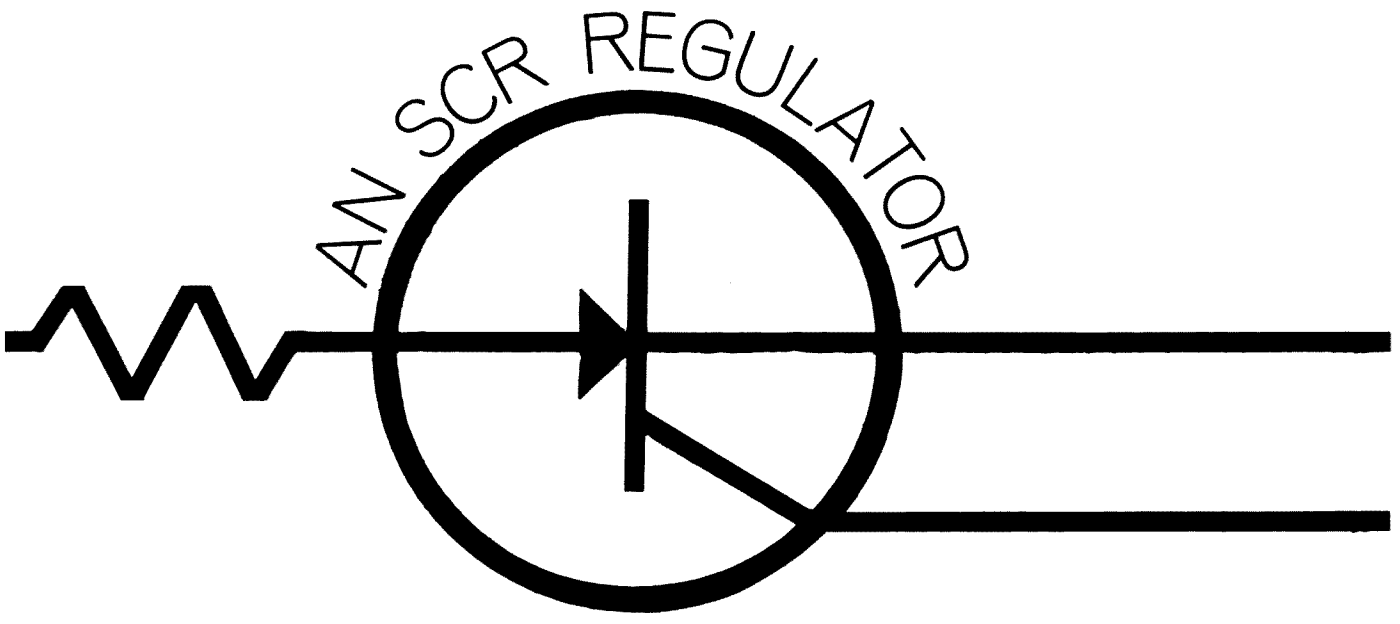
In an effort to make a long story short, we'll take up from here with the meat of the conversion information, without all my conjectures.

Start on the HR-2: Disconnect and remove the speaker completely, leads and all. It will no longer be needed. Next, unsolder and remove the little ground lug from terminal 4 on the external speaker block. Add a 3 to 5Ω 2W resistor between terminal 1 and the nearest ground. The chassis will do nicely. Now remove the external speaker jumper from terminals 1 and 2. Carefully drill a ¼ in. hole in the back plate, between the power plug and the speaker terminal board. Mount an RCA type phono jack here. Carefully remove the relay cover and observe the switching arrangement of the SPDT spare contacts. Connect the normally open spare contact to terminal 4 of the external speaker block. Connect the normally closed contact to terminal 2, and the relay tongue to terminal 3. Remove the 10.245 MHz i-f crystal and put it aside for safekeeping. It won't be needed, and may cause problems if left in. Unsolder the coax from the receiver rf deck and reconnect it to the phono jack installed earlier. This completes modifications to your HR-2.

On the Scanner, temporarily remove the speaker, leaving the wires intact. Add a 3 to 5Ω 2W resistor between speaker terminal strip lugs 3 and 4 (ground). Remove the external jumper from terminals 1 and 2. This completes modifications of the Scanner.

Assemble a short coax jumper with a male RCA phono plug on one end, and a male car-radio antenna plug (Cinch #13B or H.H. Smith #1200) on the other. This jumper will be used to connect the antenna switched by the T/R relay of the HR-2 to the Scanner. Using stranded hook-up wire, connect the following terminals together:

Scanner Terminal	to	HR-2 Terminal
1	"	3
2	"	2
3	"	4



That's all! Now hop in the car, install the two rigs, and have a ball. You may want to connect your HR-2 power cord to a switched position on your car's fuseblock, and the Scanner to an un-switched position. That way, you or anyone else can listen, but transmitting can only take place when the key is in the ignition.

You'll have a little getting-used-to-it to do, as you've gained a few knobs and switches. Don't forget to synchronize the transmitter with the channel you're being called on. Otherwise you may find yourself answering a guy on 82 when he is calling you on 94. Don't feel too bad if you do, though. I still do it occasionally.

. . .WB9FOP

Ed. Note – Since many other transceivers have extra relay contacts, similar modifications can be made. If trade-in value is on your mind, this modification is easily undone.

FOR KILOWATT POWER SUPPLIES

One evening when John (K3SGB) and I were talking about our luck in collecting parts for our linear amplifier projects, the conversation eventually turned to the power supply section. We considered the merits of both choke input supplies and capacitor input supplies and found both kinds lacking in one or more ways. For a given capacitor value, the capacitor input supply had more ripple than a choke input supply using the same or even smaller value of capacitance. In addition, the capacitor input supply had a starting current surge problem and poorer voltage stability.

For example, in a 2.5 kV supply, it is common to see 500V variations and extremely heavy starting surges. On the other hand, a choke input supply requires very high bleeder current to obtain the full voltage stability the supply is capable of. Even with a swinging choke, critical current bleeders can waste hundreds of watts. Since John and I wanted to use intermittent-voice-service rated transformers, fixed chokes of about 4H, and a filter capacitance of about 10 μF, we decided to give some thought to voltage regulators because a simple supply represented too many compromises. We soon realized that a regulator would not only eliminate the need for some of the design compromises, but that it would solve the problem of how to reduce the supply voltage during testing, tuneup, and other instances of reduced-power operation. For this purpose a Variac is usually used, but it does not solve any of the other design problems and it would cost as much as a regulator. What was needed, we decided, was a regulator which would allow us to vary the power supply output from a few hundred volts to several thousand volts, while providing excellent regulation and high operating efficiency. With these thoughts in mind I went to work and about one week later had a regulator which satisfied our goals with wide margins.

Since the type of regulator which was built is one which is rarely seen, even in commercial equipment, I have emphasized the manner in which it works rather than the manner in which it was built. This regulator is unusual because it operates on

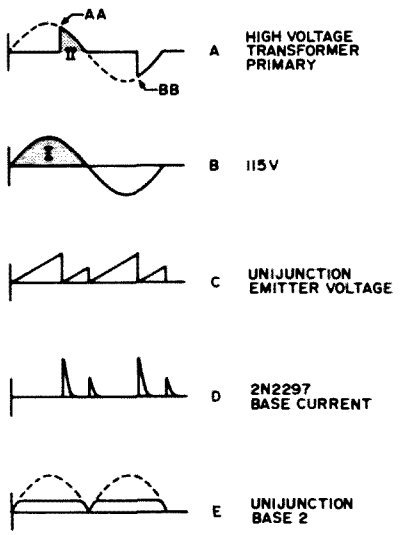

Fig. 1. Pertinent waveforms.

the primary side of the high voltage supply power transformer and manipulates the waveform which is applied to the transformer.

When a voltage such as the one shown in Fig. 1A is applied to the primary of the power transformer, instead of the sine wave shown by the dotted line, less dc voltage will be produced by the supply. This is an important point so let's see what makes it so. In a capacitor input filter, the capacitor charges toward the peak voltage produced by the rectifier diodes. Since the peak voltage of the waveform shown in Fig. 1A is less than the peak voltage of the dotted sine wave, the capacitor input supply output will be less.

In the choke input supply, the dc output voltage is more closely related to the average value (which is proportional to the area) of the rectifier waveform than to its peak voltage. If you look at the area marked II in Fig. 1A, you will see that it is smaller than the area marked I in Fig. 1B. Hence, in both types of supply, less voltage will be produced by the partial sine wave than by the full.

How do you produce this waveform? Equally important, how do you cause the points marked AA and BB to move automatically to the left when the supply voltage is too low and to move to the right when the supply voltage is too high? The answer is that you place an SCR in series with the 115V line and the transformer primary. In this circuit, the SCR behaves somewhat like a single-pole switch. The SCR switch "closes" when it is triggered and "opens" when the voltage across it becomes too small or reverses in polarity. This switch-like behavior of the SCR explains the peculiar appearance of the waveform in Fig. 1A, the voltage at the transformer side of the SCR. Due to the high currents which have to be switched, several SCRs have been paralleled. Figure 2 shows where the SCR bank fits into the circuit. Now let's see how the SCR trigger pulses are generated.

The SCR bank is shown in detail in Fig. 3. In it, the various SCR trigger pulses have to meet several different requirements. The more obvious of these is that the amplitude and duration of the pulses have to be tailored to the individual requirements of the six prime SCRs. Secondly, since these SCRs are combined into a bank, their individual requirements will translate into a combined trigger requirement for the bank. In turn, this will, as you shall see, intro-

duce a need for two additional SCRs which serve as triggers for the others. In turn again, the triggering units will have triggering requirements of their own. Finally, and most important, the trigger pulses must occur at the correct time in each half-cycle of the 60 Hz power line. Let's first consider the timing problem and then turn to the lesser trigger requirements.

In Fig. 4, above the capacitor marked "timing capacitor," there is a PNP transistor. This transistor is part of the section of the regulator which translates a control

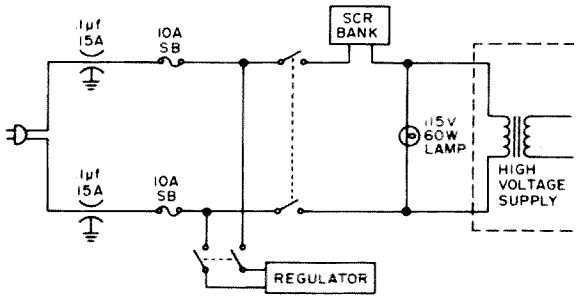

Fig. 2. Ac line connections.

voltage into proportional time delays. In particular, the PNP transistor acts as a variable source of constant current. This is not self-contradictory; the collector current is constant with respect to the collector voltage of the transistor, not its base voltage.

Since a transistor has current gain, a small base current can produce a large emitter current. Consequently, the voltage established by the resistor divider at the base of the PNP is not changed much by the small amount of base current which flows. The emitter and base potentials of a silicon transistor differ by only 0.6V so we find that the emitter voltage is very nearly the voltage which the resistor divider at the PNP base would produce if no transistor were attached to it. This behavior causes the emitter current to be determined by a base voltage, since the emitter load is a resistor whose other end is attached to a fixed B+ supply.

Finally, since the PNP collector current is almost equal to the emitter current, it too will be determined by the base voltage (as long as the collector voltage remains more negative than the emitter voltage). If no other components were present, the timing capacitor would charge constantly until its voltage reached that of the PNP emitter and then it would remain at the emitter potential indefinitely. This brings us to the 2N2646, a unijunction transistor.

The unijunction transistor, like the SCR, is also a switch of sorts. However, the conditions which cause it to switch are different from those in an SCR. Unlike an SCR, which switches when sufficient *current* flows from gate to cathode, a unijunction transistor switches when its emitter *voltage* becomes approximately 60% of the voltage at base two. When a unijunction transistor switches, the resistance between its emitter and base one terminals changes suddenly from tens of megohms to a few hundred ohms. Since the base two voltage, in this particular circuit, is never more than 4.0V, the timing capacitor is never allowed

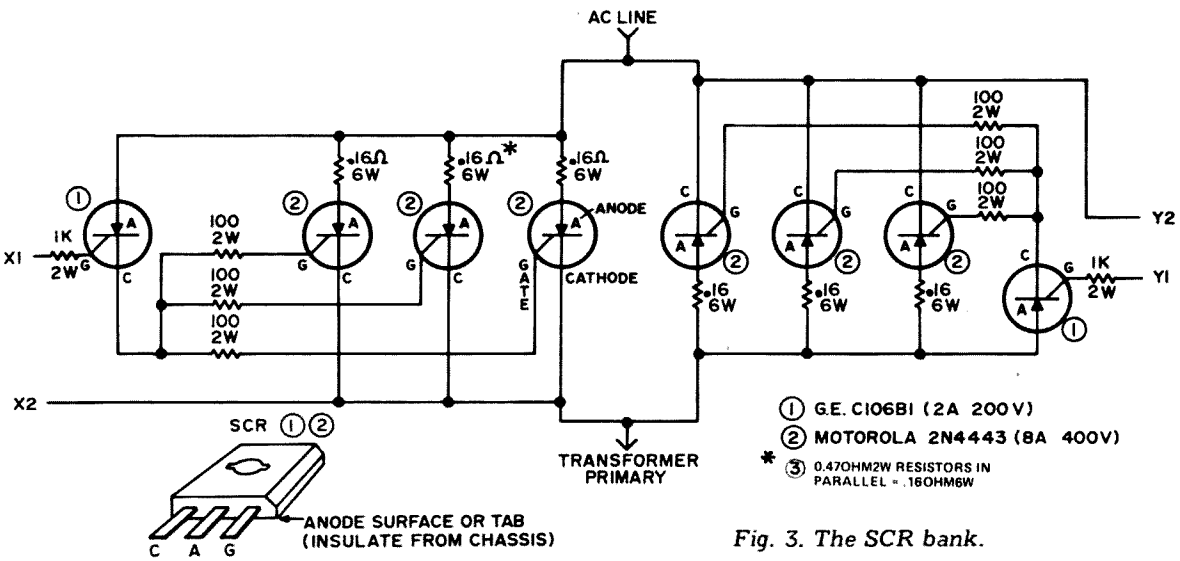

Fig. 3. The SCR bank.

to charge until it reaches the PNP emitter potential because the unijunction transistor will always switch and discharge the timing capacitor to ground first.

Once the "switch" closes, it will remain closed until the current flowing through it falls below a critical value, called the "holding current." The value of the PNP emitter resistor was chosen so that the collector current of the PNP would always be less than the unijunction transistor holding current, thereby insuring the turn-off of the unijunction transistor after the discharge of the timing capacitor. Therefore, if we start following the action at the timing capacitor, a little while after the unijunction transistor has turned off, we will see the voltage rising linearly for a while and then suddenly dropping to very nearly ground. This can be seen in Fig. 1C.

The charge stored in the timing capacitor is dumped in a few microseconds; during the dump, a current of tens of milliamperes flows into the base of the 2N2297 transistor from the timing capacitor, via the unijunction transistor. The 2N2297 further amplifies the capacitor dump current and drives the primary of a 5 μs pulse transformer. The secondaries of the pulse transformer, X1-X2 and Y1-Y2 of Fig. 4, both produce 25V SCR trigger pulses of about 5 μs duration. The emitter current waveform of the unijunction transistor can be seen in Fig. 1D. The smaller ramps and current pulses which you see in the two figures will be explained later.

As you probably have guessed, all of this switching cannot take place without some sort of relation to the ac line. All of the waveforms in Fig. 1A through 1E do, in fact, show just such a relationship.

The manner in which the unijunction switching is synchronized to the ac line is shown best in Fig. 1E. This waveform is the voltage which exists at the base two terminal of the unijunction transistor. This voltage is obtained by full-wave rectifying the 24V transformer and clipping the result with a 4V zener. Remember that the unijunction switches when its emitter voltage is 60% of the voltage at base two. Since the base two waveform becomes zero every time the ac line goes through zero, the unijunction transistor is forced to switch at the zero crossing of each half line-cycle. As a result, the timing capacitor will always have a new voltage ramp beginning at the zero crossings of the line. (If the timing capacitor is charged rapidly enough, the unijunction transistor can be caused to switch more than once during each half line-cycle. This explains the presence of the smaller ramps and current pulses mentioned before.) Since the SCR bank is turned on by the first capacitor dump after a zero crossing of the ac line, the secondary ramps will have no effect and are not important. Now let's get back to Fig. 3 and see what the rest of the SCR story is.

At 2 kW, assuming a power transformer efficiency of 80%, over 21A must be drawn from the ac line. Since an SCR operates in only one direction, there are two of them required, one for each polarity of the half line-cycles. Therefore, each SCR only needs to be rated at half this value (about 10A). This would still provide about a 2-to-1 safety factor because a normal voice waveform has about a 0.5 duty factor. To be extra safe, an SCR rated at 15A should be used.

As for its voltage, 400V gives a good safety factor with respect to the peak voltage of the power line. Rather than buy a pair of new units I used some 8A units which happened to be on hand. As you can see, I hedged the safety factors even more. The bank is equivalent to a pair of 24A, 400V units. The 0.16Ω resistors in series with each 2N4443 SCR insures equal division of the load current. These resistors must not be omitted in parallel operation if a lower current type of SCR is employed.

Due to the leakage reactance of the power transformer, the current drawn from the SCR bank during the 5 μs trigger interval is quite small. Another type of SCR, a C106B1, with a holding current of only 1 mA, is used to get the bank started. The 100Ω resistors attached to each 2N4443 gate lead equalize the gate currents so that each SCR in the bank gets an equal share of the triggering current. The 1 kΩ resistors, connected to the gates of the C106B1 triggering SCRs, prevent the load which is reflected back to the pulse trans-

former primary from becoming too large.

In order to further insure turn-on of the SCR bank, a resistive load was placed in parallel with the primary winding of the power transformer. It was found that a 60W light bulb worked quite well as the resistive load. Without the resistive load the SCR bank would not always behave properly, especially when the high voltage supply was only loaded lightly.

To review, a constant current source, a timing capacitor, a unijunction transistor, and a 2N2297 generate SCR trigger pulses once per half line-cycle. Earlier, it was stated that the supply output could be varied by causing points AA and BB (Fig. 1A) to move to the right or left. More precisely, the time which elapses between a line voltage zero crossing and the first trigger pulse to follow, will determine the supply output voltage. This time delay is inversely proportional to the magnitude of the constant current produced by the PNP transistor. That is, to make the time delay half as large, double the constant current. Since the charging rate of the timing capacitor is controlled, indirectly, by the base voltage of the PNP transistor, we must consider the manner in which this voltage is varied. This brings us to the next major section of the regulator circuit, the IC differential amplifier.

Externally, the differential amplifier looks somewhat like a conventional transistor, except for its additional leads. Electrically, there is a vast difference. Within its metal can there are over a dozen transistors and as many more resistors, connected together to form an entire circuit. In short, it is an integrated circuit. Specifically, it is a differential amplifier. A differential amplifier, by definition, has an output voltage which is proportional to the *difference* of two input voltages, rather than to the voltages themselves. In the National Semiconductor LM201, the kind which was used, the output voltage is typically 25,000 times the difference of the input voltages. In this circuit, one side of the amplifier input is connected to ground via a 1 kΩ resistor. The other amplifier input is connected to a minus voltage reference and the positive voltage output of the high voltage supply. The resistor values have been chosen so that by varying the potentiometer, marked "voltage adjust" (Fig. 4) the supply output can be varied from less than 100V to over 3.5 kV. If the input of the amplifier, at which the minus reference and the positive output voltage are combined, differs from ground potential by even a few millivolts then the amplifier will produce several volts of corrective action at its output.

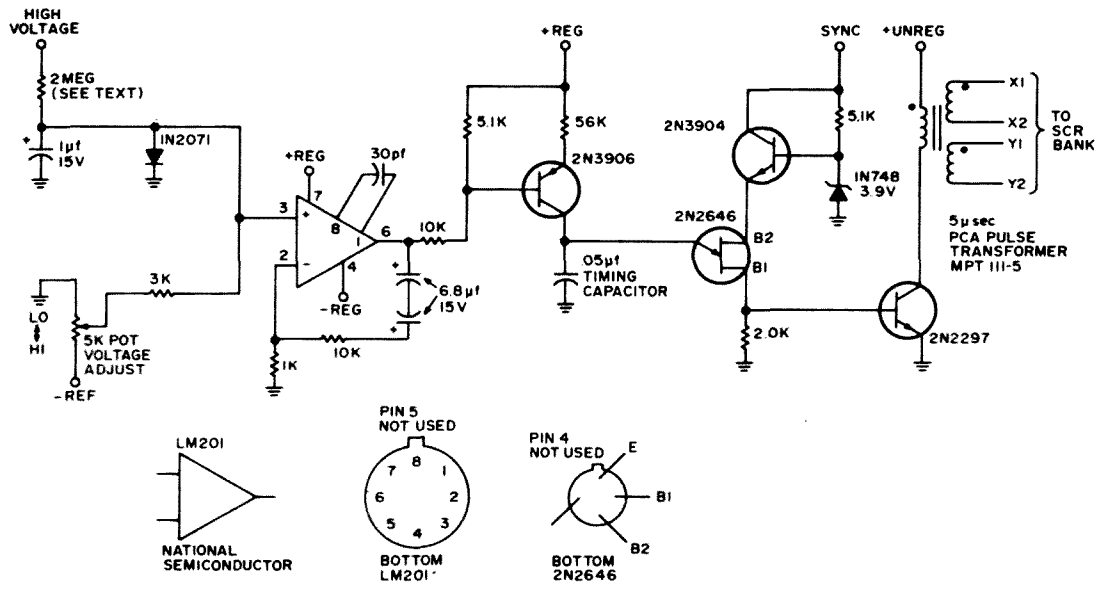

Fig. 4. Error amplifier and trigger generator.

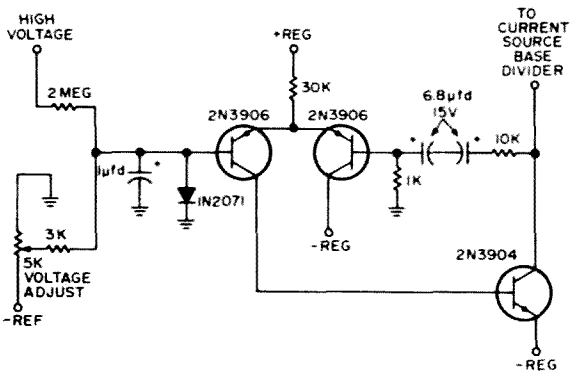

Fig. 5. Cheaper differential amplifier.

This particular differential amplifier costs about $13, a price which some of you may prefer not to pay. This amplifier is so good that it almost overkills the problem. Since the regulator circuit will work with other amplifiers, you may want to try a cheaper unit just to get the regulator on the air. There are many fine IC amplifiers available at less cost; if you use another type be sure to get the data sheet for it from its manufacturer. Follow the manufacturer's recommendations or you will probably end up with an oscillator instead of an amplifier.

If you would prefer to build your own amplifier, you can try the one shown in Fig. 5. It should cost less than $2 even if you buy all of the parts new. I did not try the cheaper amplifier so it may not be completely compatible. If any tweaking of values is required, the parts which are most likely to need the tweaking are the 6.8 μF feedback capacitors and the 10 kΩ resistor in series with them.

I have used the three-transistor amplifier in other circuits and found that it usually has a gain of 300.

With a constant load on the supply, you should see a voltage of nearly zero at pin 2 of the differential amplifier. You may wonder why this pin is not simply grounded. The reason is that the speed of response of the amplifier must be reduced. Due to the high gain of the amplifier and also the fact that only one corrective decision can be made in any given half line-cycle, the regulator would hunt around for the correct voltage without ever finding it. During one half line-cycle the regulator

would produce a minimum time delay and in the very next one it would produce a maximum delay. The three components which are connected to terminal 2 of the amplifier prevent the overcorrections from occurring.

Finally, we get to the regulator power supply. There is nothing unusual about it aside from the fact that one of its outputs is an unfiltered full-wave rectified sine wave. Zener diodes and emitter followers provide a regulated B+ and two regulated B– voltages. The complete power supply circuit is shown in Fig. 6.

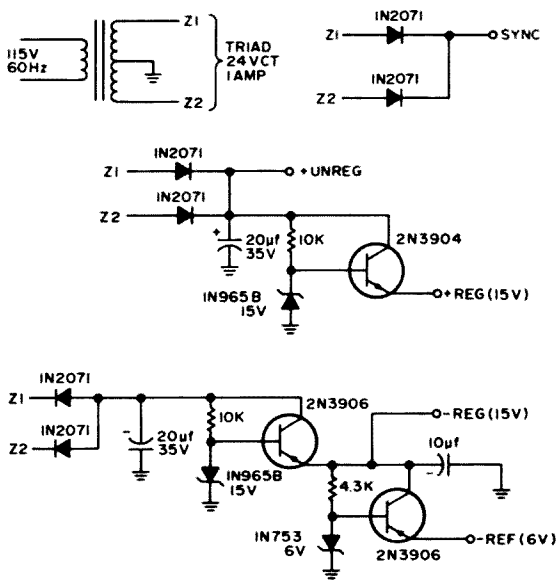

Fig. 6. Regulator power supply.

There is not a great deal to be said about construction of this circuit, because there are no hidden traps awaiting you. Obviously, with a very high gain amplifier you should keep the lead lengths at its input short. Also, since large currents are being switched, you should use sufficiently heavy wire, fuses, switches, etc. Finally, again because currents are being switched, you should enclose the circuit and not omit the 0.1 μF line filter capacitors. The unit I built was contained in a 2 x 5 x 7 in. chassis and the regulator circuit was placed on a 3 x 3 in. printed circuit.

One more caution: Use ten 200 kΩ resistors in series, rather than a single 2 MΩ resistor, in the return from the supply output to the amplifier input, in order to stay well within the resistor manufacturer's maximum voltage and power ratings. The 2W size is fine.

Now I am sure you will want to know how well the regulator circuit works. To test it, I borrowed a Heath model HP-24 kilowatt power supply. This is a capacitor input filter supply which has a no-load output of 2.5 kV. A knife-switch-controlled dummy load, which drew 600W from the supply, was assembled. (For safety, the knife switch was operated with a 1 ft wooden dowel.) Without the regulator, the supply dropped from 2.5 to 1.9 kV when the load was switched in. With the regulator, the supply was set at various voltages below 1.9 kV with no load. After the load was switched in, there was no net voltage change discernible – not even one meter pointer's width! I checked the transient response at a 1.9 kV setting scope and found that the supply voltage dropped 80V when the load switch was first closed. One half line-cycle later, the voltage had recovered 40V out of the 80V, and during the next half line-cycle, the remainder was recovered. I had no way to test the supply with voice modulation; however, I think that the 600W test was severe enough to be representative. As a guess, I would expect to see about ±50V variations with the Heath supply and voice loading.

The switching hash level was checked with a receiver which was plugged into the same line as the regulator. With no line filtering, there was no hash on the bands above 40 meters and the hash was only about S7 on 40 meters. On 80 meters it was quite loud. If you use the 0.1 μF line filters and keep the rest of the circuit in a small chassis, you should not have any hash problem on any band.

As a final check, a 14A electric heater was used as a load and the regulator was run for 15 minutes. After the 15 minute trial, nothing was more than lukewarm, except the electric heater.

If you do decide to try building this regulator, don't make it your last project – 3000V power supplies are dangerous!

JUGE

A message from .....

ED JUGE, W5TOO/W5NGL

ED JUGE ELECTRONICS, INC.
3850 South Freeway
Ft. Worth, Texas 76110

Phone (817) 926-5221

Until recently, "Juge" has been a new name to most of you, I'm sure. The first question we get is "How do you pronounce it?" Answer. . . it rhymes with huge". In order to induce you to trade with that guy whose name you can't pronounce, we've gone overboard to provide something different in ham stores. We started in business just over eight years ago, and built our new building two years ago. It has been called the best looking of its kind in the U.S. by every single factory man or out-of-town visitor who has seen it. We stock most major brands, and a good selection of used equipment. We select our merchandise carefully. . . as if we were going to use it ourselves. (All of our sales and service personnel are licensed hams.) We specialize in personal service to our customers, and treat each one as an individual with his own special interests and his own unique needs. We also realize that when you write to us for prices or information, you want an answer now, not two weeks from now. . . and you'll get it! When you order from us, we know how it feels to finally decide to make a purchase. . . your only regret is that you didn't order last week so you could have it now. Normally, your order will be shipped the day it reaches us, the following day at the latest, unless of course, as will sometimes happen, we're out of stock on your item. When that happens, we order your item immediately via telex or telephone, and when possible, request the factory to ship directly to you to avoid delays. We do all we can to cut any delays to an absolute minimum. When we deliver an item to a customer over the counter, we normally open it and check it for him to be absolutely sure it is right before he leaves. . . we'll do the same thing to your mail order, if you will request it when you order. Some hams do not want the factory-sealed box opened, so we ship that way unless you ask us to check it (and we would prefer to check if you don't object). We have an excellent service department, should you have any problems with new or used gear, and we maintain a good parts stock too. If you wish to purchase your gear on time payments, we accept Bankamericard or Master Charge, or we can finance through General Electric Credit Corporation with 10% down and up to three years to pay. For those who prefer "cash discounts", we do offer them on those lines commonly discounted. Such prices are competitive, but firm. We are in business to make a profit, and know what it takes to stay in business, so we don't try to beat. . . just compete. On "cash" prices, we do not pre-check gear, nor do we offer our store warranty. In other words, we offer competitive service to go with competitive prices. We close on Sunday and Monday to give us time to catch up with our paper work so we can continue to provide the kind of service you want. Our phone is answered automatically 24 hours each day while we're closed and after regular hours so you can call in your order. Phone us at (817) 926-5221. Telex us at 75-8329. Write to the address above. You'll find "southern hospitality", personal service, and a real friendly bunch of hams who sincerely want your business.

THE 1296'er: IDEAL CRYSTAL OSCILLATOR

This details the design of a crystal-controlled oscillator especially designed for 1296 multiplier service, and begins a series on the construction of a complete solid state low-cost rig for 1296 MHz. With transistors that work well in the 2400 MHz band, 1296 should be easy. Well, it isn't all that easy, but with a little care for detail it can be done. A large part of the receiver starting from and including the 28 to 30 MHz tuneable i-f section, through the 1.65 i-f, the 135 kHz i-f, and the audio, all using IC's (integrated circuits) has or will be detailed in articles in 73 Magazine. All you need to complete the receiver is the converter and one or two low noise stages on 1296, and these will be described later on.

We will go into this 1296 in easy stages, with an "Ideal" crystal oscillator first.

Towards An Ideal Crystal Oscillator

This just happens to be the best crystal oscillator I've ever made. Actually it didn't just happen. I worked hard on it. We're going up to 1296 so we need all the "sock" we can get and still have a good, reliable, stable oscillator. This one has the punch – 168 mW rf output at last measurement, it stays right in the pass-band of my lab receiver, comes on the air every time the switch is thrown, and uses the Motorola HEP 55 transistor (only $1.20). This is my Universal Device, which seems to be good for almost any stage anywhere.

This oscillator works with full power on all the crystals I have around in the shack from 45 to 54 MHz, and is the result of over thirty years of working with control crystals. Off and on I should say, and for the last ten years with greater and greater emphasis on transistor units. And the last few days full time to bring you a low-cost excellent design. If it isn't the ideal, it's awfully close!

How It Works

Referring to Fig. 1, NPN Q1 is turned on by supplying positive voltage to the collector and base, causing current to flow. Turn on current and "graininess" in the collector current of L1 is fed back to the base circuit through the control crystal, which reverses the phase (see detail below). Q1 amplifies these minute pulses which in turn resonate in the L1,C1 circuit, and the oscillator takes off, on the crystal frequency only, however. A piezoelectric crystal such as quartz operates by means of compression and extension waves in the crystal. These are also known as sound waves. They are in the form of maximized standing waves which bounce back and forth between two crystal surfaces (outer

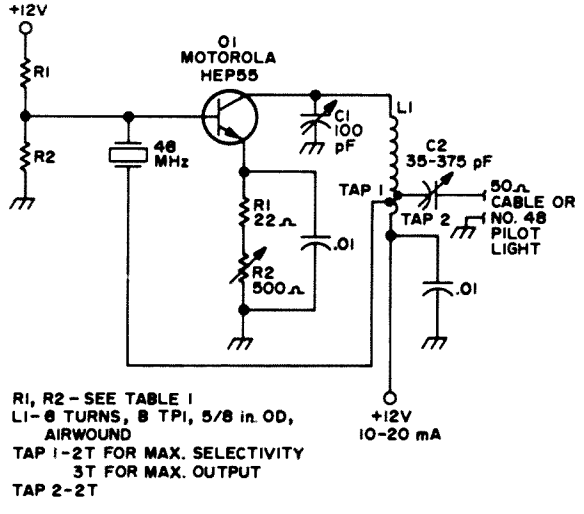

Fig. 1. Ideal crystal oscillator.

wall, or air surfaces) which furnish a high degree of reflection. At one part of the cycle (48 million per second in this case) one side of the crystal is positive and the other negative. The next half cycle, the polarities are reversed under the influence of the ac voltage. Also in this case there is more than one cycle through the cyrstal thickness, but as long as there are an odd number of half waves (sound waves) it will work. This basic action of control crystals thus causes a 180 degree (or nearly that amount) phase reversal from one side to the other, the feedback path from the collector coil L1, which started out *in* phase, reaches the base *out* of phase, which is the proper condition to cause oscillation.

Power can be adjusted by the emitter pot R2, and a fairly good output match can be obtained with tap 2 and C2. Good luck.

Base Bias

This was quite a revelation. I found that almost any combination of R1 and R2 could be used as long as the voltage was right, and this was not critical, except for pushing maximum power out. Table 1 shows representative values for R1 and R2 that resulted from the test runs on this parameter. There appears little difference in power output so you can use any of the values shown. I generally slap in a 5K and a 1K and that's it.

Emitter Bias

This is not in the least critical either. Smooth control of the current and the output rf power is found with R2, varying from 160 mW down to less than 10 mW. And that's it for bias.

Crystals

Using the finished circuit of Fig. 1, four crystals on 48 or 48.1 MHz were tested. A ¾ in. square one was excellent, and three in the small case size ½ in. long by 3/8 in. wide worked just as well with full power out.

Note that the circuit is using quite a lot of feedback, with good output loading also. This can be desirable for multiplier service which we are building here, but if you don't need maximum output you can drop both Tap 1 and Tap 2 down on the coil towards the cold end.

Table I

R1	R2
5K	1K
10K	2K
25K	5K
35K	10K

The Inductance

Several coils were tried in the L1 position, as you may not have some of those air-wound jobs on hand, or you might want to save space and use smaller coils. Coil B gave the same output of 160 mW of rf, the same as coil A, as far as I could determine, which is about plus or minus 5 mW, but did not tune quite as smooth as I would have liked. It had a tendency to jump a little in power as R2 was turned down.

Coil C behaved exactly like coil A, so use C instead of B for smaller size work. The Q of a small size oscillator coil in the maximum load condition is evidently not very different than that of a larger coil.

Feedback tap. This is not too critical, but it should be positioned for the results needed. The ratio of turns from Tap 1 to the cold end, to the number of turns from Tap 1 to the high end is about one to three, as you can see in Fig. 1. This is for maximum output. For maximum selectivity and sharper tuning a slightly larger ratio, with the tap nearer the cold end, is preferable.

Plenty of feedback (lower ratio) is probably best for driving a tripler, which likes a lot of harmonic content.

Output tap No. 2. This is mainly a question of loading and matching, and the series output capacity C2 plays an important part here. A good match to a No. 48 test bulb for milliwatt determination can be obtained with between 50 and 100 pF. For a 50Ω cable, more capacity may be needed.

An excellent crystal controlled oscillator for tripler driving has been described in detail, which should start you off on the way toward an interesting solid state 1296 MHz rig. . . . K1CLL■

FOR FRUSTRATED NOVICES:

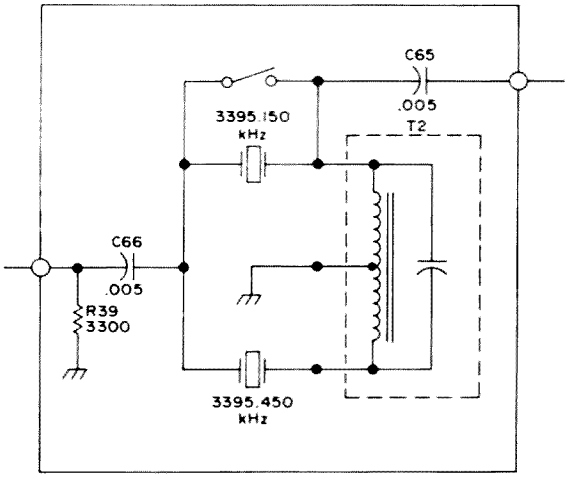
Listening to 'Phone with the HW-16

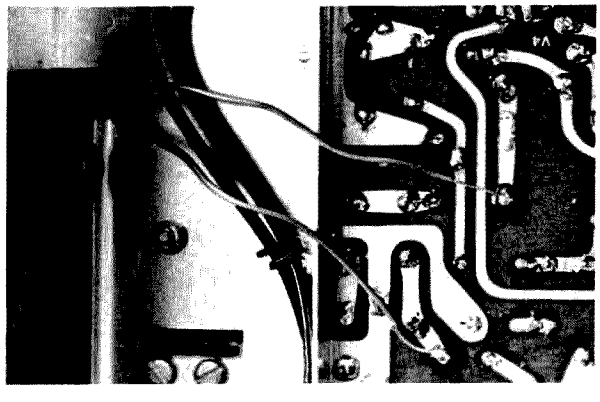
The Heathkit HW-16 transceiver is a fine, inexpensive rig for CW, and for this reason many Novices use it. Its excellent selectivity (500 Hz) makes copying CW easy and pleasurable.

However, it is a rare Novice who doesn't get bored occasionally with code and would prefer to listen on the phone bands for awhile. It is here that the good selectivity of the HW-16 works against the Novice. The rig's narrow bandspread makes copying SSB or AM nearly impossible.

Since the HW-16 covers a portion of the 40 meter phone band, decreasing the rig's selectivity would allow the Novice operator to listen to the goings-on on this phone band. Happily a simple modification is all that is needed to provide this decrease in selectivity whenever the operator desires it.

The switch can be placed on the rig as shown or in any other convenient location.





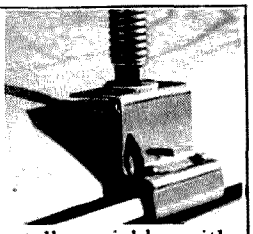


Fig. 1. The new switch runs from C65 to C66, in parallel with the upper crystal.

The lead wires can be soldered to the circuit board and run up to the switch through the opening in the chassis for the tuning dial.

As can be seen in the accompanying schematic (Fig. 1), capacitors C65 and C66

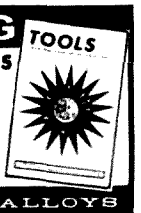
on the receiver circuit board are connected through an SPST switch. When the switch is closed, this new circuit decreases the effectiveness of the crystal filter enough to allow perfect copy of SSB and AM signals. When the switch is open the original CW selectivity is not affected.

The new switch can be mounted on the front panel of the HW-16 as shown.

There are other uses, "byproducts," of this modification. It can be used in the CW bands to scan a much larger portion of the band than would ordinarily be possible with the rig's normal selectivity. Another possible use is listening to the foreign broadcast stations on 40 meters. And what about a Novice net where all the stations aren't on the same frequency? It's very convenient there, too.



This is just a minor modification, but it can take a deficiency of your HW-16 and change it into versatility, thereby making the rig easier and more enjoyable to own and operate.

My thanks go to Steve (WA2JZJ) for the excellent photographs. . . .WN2REW

FM ADAPTER

requency modulation on the 2m band is increasing in popularity. One of the reasons is the availability of surplus FM equipment which can be converted to this use. However, the principal advantages of the FM mode are:

1. Improved signal-to-noise ratio.
2. Freedom from pulse-type interference.
3. Reduction in TVI.

A large percentage of the VHF receiver systems used by amateurs consist of crystal controlled converters ahead of a conventional hf receiver. It is possible to receive FM signals on such a system by detuning slightly so that the center frequency of the FM signal is at the steepest part of the i-f response curve. However, the noise and interference reduction advantages of FM cannot be realized under these conditions.

To realize the full merits of FM reception, an FM adapter can be used with a conventional hf receiver. The adapter to be described operates at an intermediate frequency of 455 kHz with a low impedance input. The latter permits use of coax cable connection to the hf receiver without disrupting the normal operation of the latter.

Figure 1 is a schematic diagram of the adapter. Metal work consists of components from the Lektrokit* chassis system. Four 4 x 4¾ in. chassis plates were used as follows:

Plate No. 1 carries the 6C4 buffer amplifier, first i-f transformer, 6AU6 first limiter, second i-f transformer, 6AU6 second limiter, discriminator transformer and 6AL5 discriminator.

Plate No. 2 carries two 5751 tubes, comprising the squelch and first audio section, the 6BQ5 audio power amplifier and the audio power output transformer.

Plate No. 3 holds a plug-in 20/20 μF 450V electrolytic capacitor, a plug-in rectifier assembly, 1N2389, and an OA2 regulator tube.

The fourth plate is taken up by the power transformer.

EXPERIMENTING IN FACSIMILE?

The leading manufacturer of 18" facsimile weather chart recorders is in the process of converting an existing network for fully automated weather chart transmission. This conversion will make available a number of used 18" weather map recorders ideally suited for use by anyone interested in experimenting with facsimile.

They include the recording head, all necessary electronics including automatic start, phase and stop circuits. Operating at speeds of 60, 90 or 120 rpm (depending on model), these recorders, with suitable receiver and FSK converter, can be used to monitor radio weather chart broadcasts from stations located around the world or modified to accept press wire photo transmissions or modified to receive transmissions from orbiting weather satellites.

These recorders are available strictly on a first-come, first-served basis.

Call or write Mr. Armand D. Bouchard
ALDEN ELECTRONIC & IMPULSE RECORDING EQUIPMENT CO., INC.
Washington St., Westboro, Mass. 01581
617-366-8851

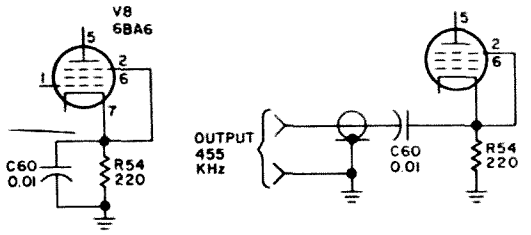

Fig. 2a. Original schematic GPR-90
b. Modified schematic, GPR-90.

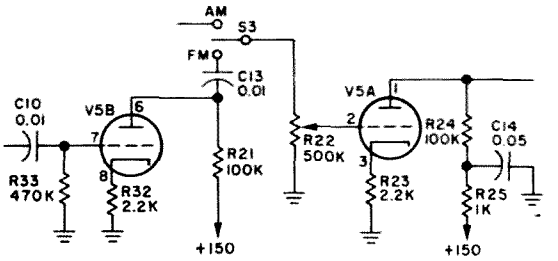

Fig. 3. Audio circuit without squelch.

The i-f input receptacle, J1 the accessory output receptacle, J2, and fuse, F1, are mounted on the rear panel of the chassis assembly. The front panel carries the audio output jack, J3, the power switch, S1, volume control, R22, AM-FM switch, S3, squelch adjust, R15, meter switch, S2, and the tuning meter, M1.

Buffer stage, V1, provides a low impedance input and isolates the first i-f transformer from the influence of external connections. If the hf receiver does not have a low impedance output, one can be provided fairly simply. Figure 2 shows how this was done for a GPR-90 receiver. Figure 2a is a partial schematic of the third i-f stage. Figure 2b shows the change to give a low impedance output; the bypass capacitor for the cathode resistor of the third i-f tube was lifted off ground and taken to an output jack. A shorting plug can be applied to the output jack when the FM adapter is not in use. It should be noted that the bandwidth at the receiver output jack is governed by shorting plug can be applied to the output jack when the FM adapter is not in use. It should be noted that the bandwidth at the receiver output jack is governed by the preceding stages. If wideband response is required, the takeoff should be at an earlier i-f stage (with subsequent loss in gain).

V2 functions as a conventional amplifier-limiter. Its input and output uses conventional 455 kHz i-f transformers. V3 acts as a limiter for FM reception, but is a detector for AM reception. In the latter case, the AM envelope is taken off the grid resistor, R5, for V3.

*A.P.T. Electronics Industries, Ltd., Chersy Road Byfleet, Surrey, England.

A discriminator transformer, T3, was produced by adding the phasing network C6, R7, to a standard full-wave detector transformer. V4 is a Foster-Seely discriminator. It provides the following outputs:

1. Audio signal through coupling capacitor C10.
2. AGC voltage through R10 and J2 to the hf receiver.
3. Squelch voltage through R10, V6B and R12 to the squelch tube, V5A.
4. Tuning indicator voltage through R10 and R13 to the tuning meter, M1.
5. Discriminator voltage through R11 to the tuning meter for tuning or adjustment of T3.

V5B is a squelch-controlled audio amplifier which is used only for FM reception. V6A and V7 form the remainder of the audio system. The cathode resistors for V7, R27, R28 and R29, form a voltage divider to obtain approximately +2.5V delay voltage for the squelch tube, V5A. V6B is used as a diode to isolate this positive voltage.

With no input signal to the adapter, the positive delay voltage appears at the grid of the squelch tube, V5A, causing the tube to draw maximum current. The current flowing through its plate resistor, R17, produces a voltage drop at the grid of the first audio tube, V5B, thus cutting off operation of this tube. For signal conditions, the negative squelch voltage, applied through the diode, V6B, overcomes the positive delay voltage. This cuts off squelch tube, V5A, and the first audio amplifier stage operates at normal gain. The sensitivity of control for V5A is adjusted by R15.

In case it is not desired to incorporate the squelch circuitry, one 5751 tube can be eliminated. The audio schematic would then be as indicated in Fig. 3.

It should be noted that all stages, except the audio power amplifier, operate from a regulated plate voltage of 150. The PA stage has a 500Ω output. A 5000Ω to Voice Coil transformer may be substituted for T3 if desired.

In order to insure compatibility with the hf receiver with which this FM adapter is to be used, it is desirable to use all the receiver during the alignment process.

Set the signal generator for any convenient frequency within the range of the hf receiver and turn on the tone modulation. Tune the receiver for maximum response as indicated on the receiver's S-meter. Set adapter mode switch to FM and the meter switch on TUNE. Adjust T1, T2, and T3 for maximum response on the meter. Throw meter switch to DISC. and adjust the secondary of T3 so that the meter reads zero center. At the same time, monitor the audio output which should decrease in level as the meter needle is centered. Turn off the signal generator and adjust the squelch control, R15, so that the background noise in the output of the FM adapter just fades out. This completes the alignment.

In operation, the meter switch is normally left on TUNE. However, the discriminator adjustment should be checked occasionally by switching the meter to DISC.

This unit should provide quiet, effective reception of FM signals. All parts are readily available and the chassis system makes construction simple.

FIELD INTENSITY AMPLITUDE MODULATION
Amateur Do-It-Yourself
Directive Displacement Modulation
Guaranteed FIAM Specifications:
1. The only known modulation system that is compatible with AM & SSB.
2. Use FIAM secret comm. system between two stations.
3. Uses the same FIAM control unit for 6 thru 20 m. Yagi Antennas.
4. Tests indicate less cross talk.
1. Free typical FIAM Receiver Adaptation details. Postage ..... $ .10
2. FIAM Construction & Operation Manual. (Postage Included) ..... $ 1.25
3. 2 Modulation Control units. 36.95
4. Postage & H.C. for item 3 ..... .50
5. Additional components (purchased from others). 40.00

TRANSCEIVER POWER SUPPLY

he power supply shown in Fig. 1 delivers 700V dc @ 200 mA, 250V dc @ 300 mA, and −100V dc. It works very well with the Heathkit SB and HW series transceivers. It also works fine with the National NCX-3, NCX-5, and 200 transceivers and any other rig requiring these voltageds. The transformers are salvaged from old TV sets. Diodes and capacitors are available from surplus outfits for very low cost. The total cost should be less than $15. The Cinch-Jones type plugs used in many rigs are available from John Meshna (19 Allerton St., Lynn MA 01904) for 50¢ each.

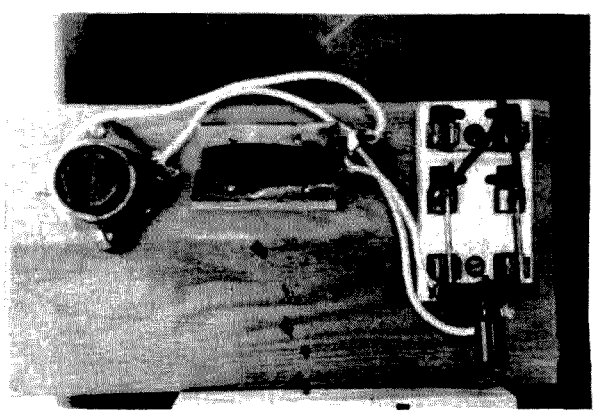
Easily Made Electric Timer



Here is a practical, useful little gadget that is easily constructed, and is so simple, it is ideal for a first construction project for a Novice. Just a simple timer that will turn a rig on automatically so when your sked time arrives, the rig will be all warmed up and help avoid undesirable frequency drift.

The heart of this timer is a cheap alarm clock. One that, when the alarm goes off, a key on the back of the clock turns or unwinds. My clock cost $1.98 and has worked perfectly now for four years. When the key turns, it drops off a shorting piece of metal, closing the ac circuit, as explained below.

The base board may be of any material. Mine is just a small board, 5 x 7 in. Its size, and the arrangement of parts, is not critical. If you wish you may rig a dust-cover, using a cardboard box painted with black paint.

You will need these parts: clock, ac plug and cord to reach from timer to electric outlet supplying current to your rig, DPST switch to open the ac line, socket to plug your rig into and a fuse holder and fuse, if you wish one. The switch that does the turn-on job is made from 2 lengths of ¼ round wood, about 3 in. or so long. You will need a few square inches of copper foil to cover the ¼ round wood pieces.

Glue a brad about 3/8 in. or so long onto the key on the back of your clock. Use

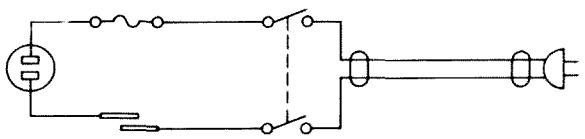


Fig. 1. Timer. Parts: 1. Socket to plug transmitter into. 2. Fuse – any kind is OK. 3. Switch – 2 pieces of ¼ round, copper covered. 4. DPST switch. 5. Cord long enough to plug into electrical outlet. 6. Plug.

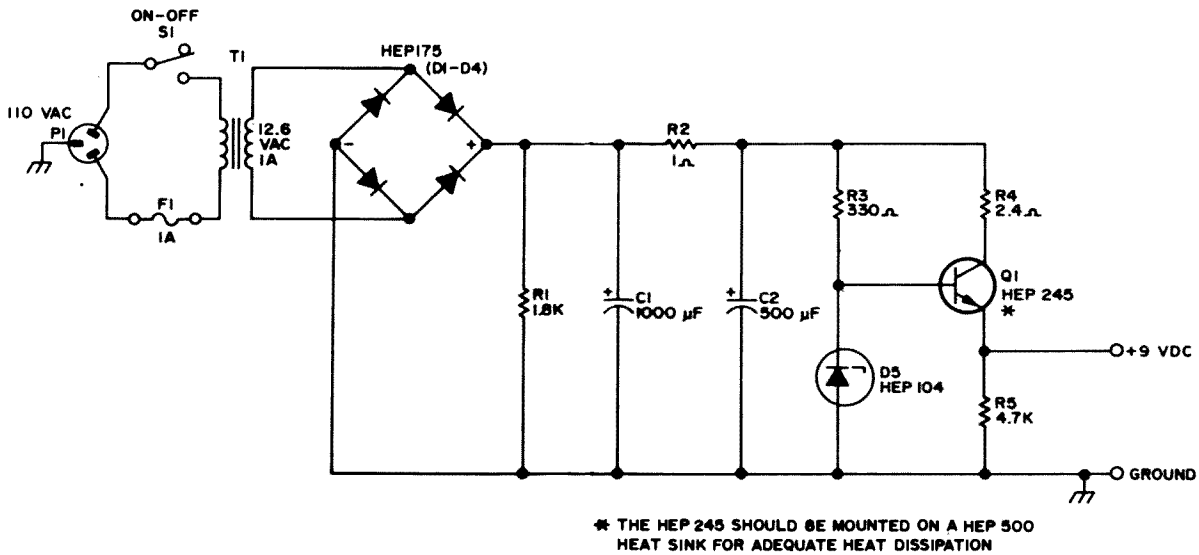
epoxy glue, and it will hold for years. Cut a brass or copper disc or square piece of stock about 5/8 in. or so, round or square, and drill a small hole in it toward one side, to fit easily over the brad on the clock key.

Cover the two pieces of ¼ round with copper foil and connect a wire to each and fasten the ¼ rounds to the base, very close together. The distance apart is such that when the metal piece drops on the two ¼ round pieces, it closes the circuit across the two pieces. Leave room for your clock to sit on the base, directly in front of the ¼ round "switch."

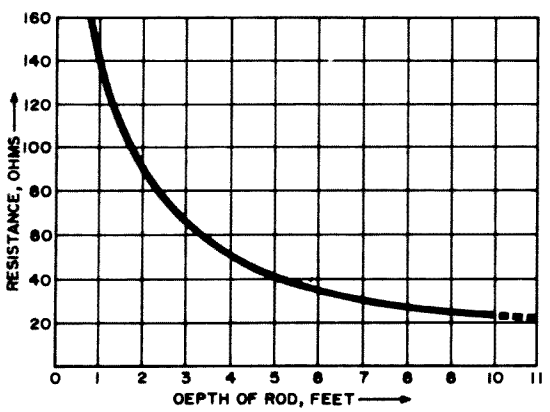
Set the alarm on the clock for the desired turn-on time; put the piece of metal on the brad on the clock key, and set the clock on the base so that the brad is up above the ¼ round "switch." When the alarm sounds, the key will turn, dropping the metal piece off the brad and letting it fall onto the "switch," closing the circuit. That's it!

I leave the rig switch on, and turn the rig off by opening the DPST switch, which takes all current off everything so you can pick up the metal piece and have it ready for the next time. Be sure to use a double pole switch so that both sides of the ac line are entirely cut off. If your junkbox won't provide a DPST switch, you can buy one at a very low price.



My timer uses a DPDT switch with one pair of contacts not used – just because I had this switch in the junkbox.

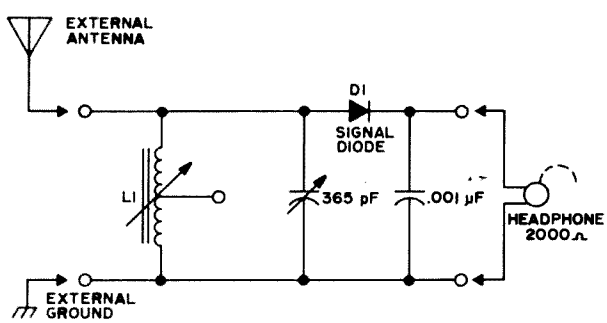
. . .W6LM



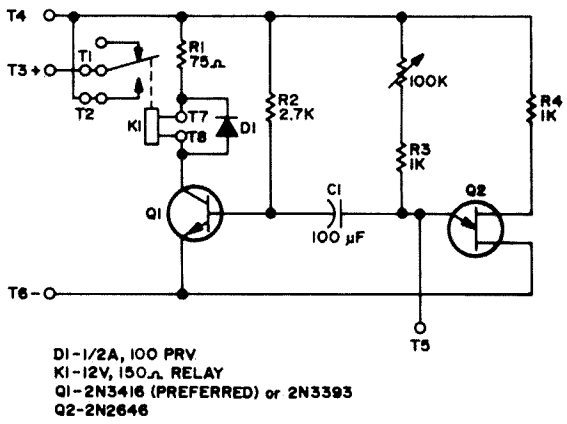
CIRCUITS, CIRCUITS, CIRCUITS...

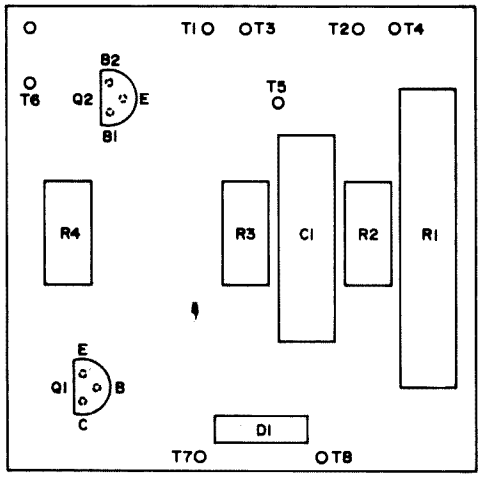
The following circuits have appeared in the referenced books, magazines, application notes, etc. While we try to reproduce all of the information that should be needed by an experienced constructor, readers may want to avail themselves of the original sources for peace of mind.

Readers are requested to pass along any interesting circuits that they discover in sources other than U.S. ham magazines. Circuits should be oriented toward amateur radio and experimentation rather than industrial or computer technology. Submit circuit with all parts values on it, a very brief explanation of the circuit and any additional parts information required, give the source and a note of permission to reprint from the copyright holder, if any, and the reward for a published circuit will be a choice of a 73 book. Send your circuits to 73 Circuits Page, 73 Magazine, Peterborough NH 03458.



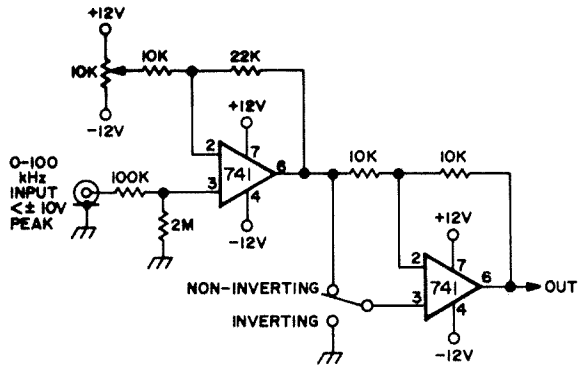
Simple power supply. Circuit courtesy of Motorola Construction Projects.



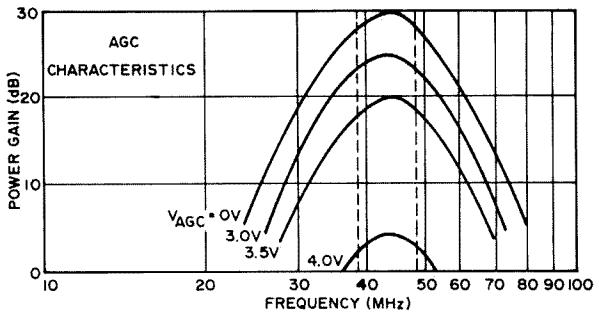


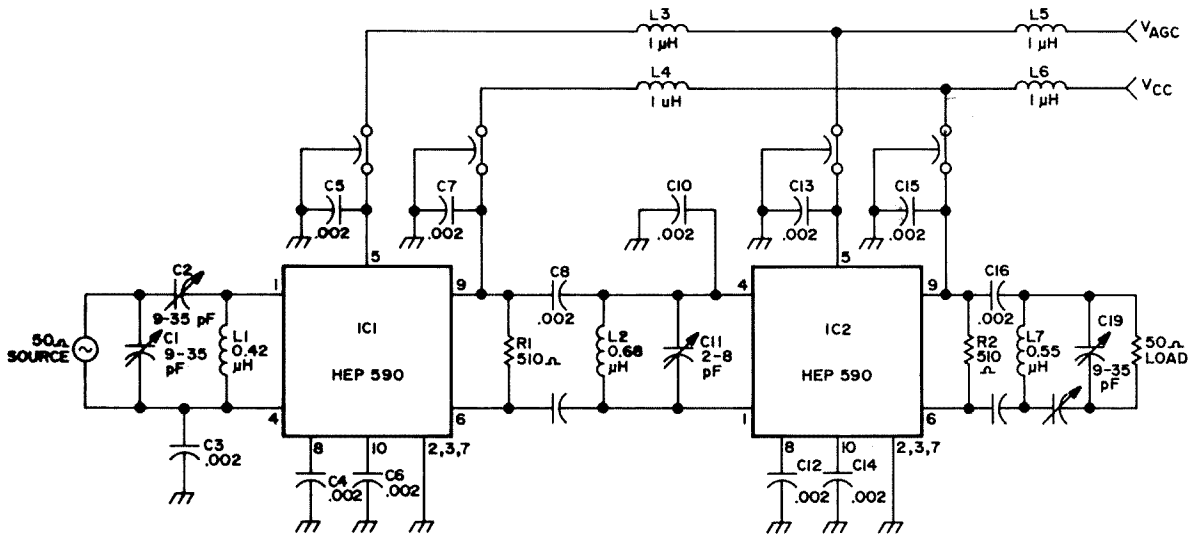
EARTH RESISTANCE DECREASES WITH OEPTH OF ELECTROOE IN EARTH.

When you find that your earth-electrode resistance is not low enough, there are several ways you can improve it: 1) Lengthen the earth electrode in the earth; 2) Use multiple rods; 3) Treat the soil. As you might suspect, driving a longer rod deeper into the earth, materially decreases its resistance. In general, doubling the rod length reduces resistance by about 40%. *The curve at left shows this effect. For example, note that a rod driven two feet down has a resistance of 88Ω; the same rod driven 4 feet down has a resistance of about 50Ω. Using the 40% reduction rule, 88 X 0.4 = 35Ω reduction. A 4-foot deep rod, by this calculation would have a resistance of 88–35 or 53Ω – comparing closely with the curve values.*

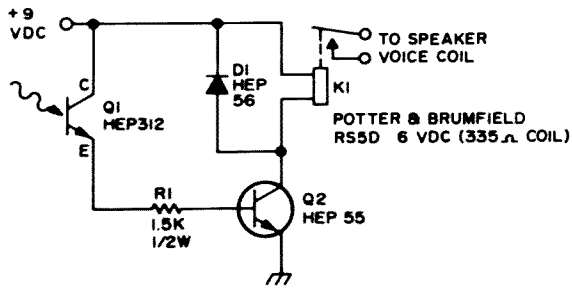


Crystal diode receiver, the simplest radio possible, runs forever without batteries. Signal diode is Calectro K4-550. Circuit courtesy of GC's Calectro·Handbook.

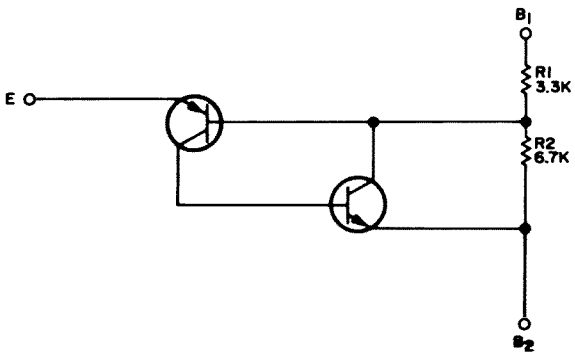


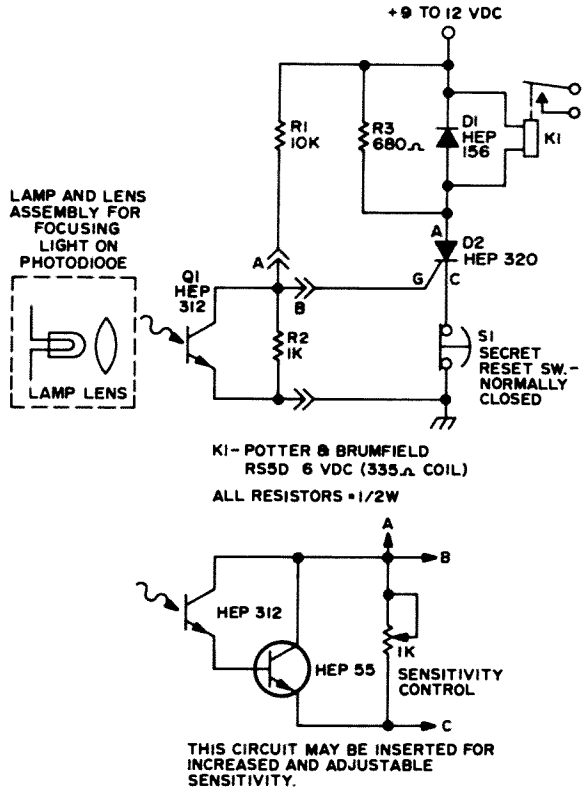


Timer board, adjustable 0 ~ 20 seconds. R1 – 12V, 150Ω relay; D1 – ½ amp, 100V; Q1 – 2N3416 (preferred) or 2N3393; Q2 – 2N2646 (K6AEH).

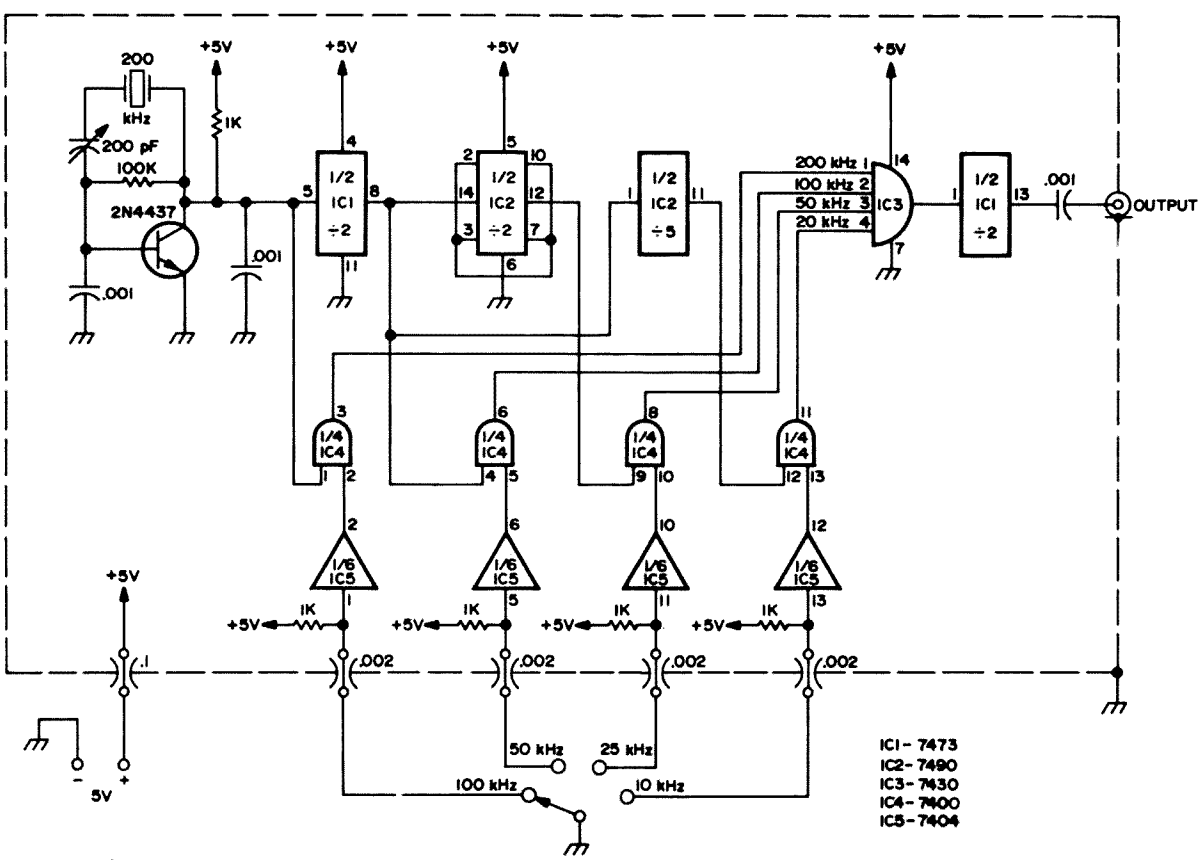


Low speed counter, scope or audio dc input level and polarity switcher. This circuit will change the level of the input signal by means of the pot. The polarity (rise and fall) may be inverted by means of the switch. (Thanks to WØLMD)

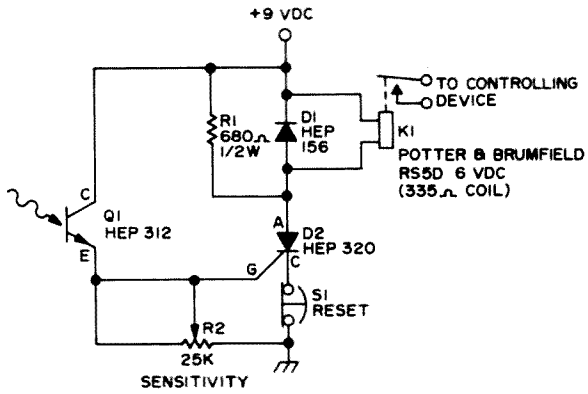




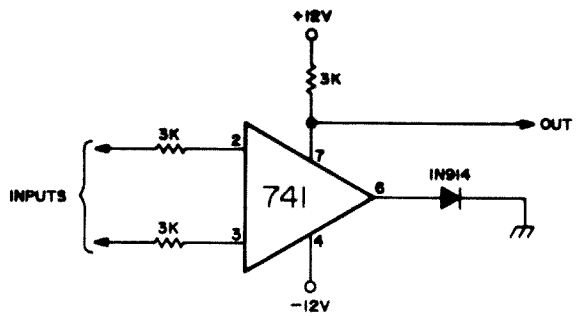
Wide band 45 MHz amplifier, with chart showing AGC characteristics. Circuit courtesy of Motorola.



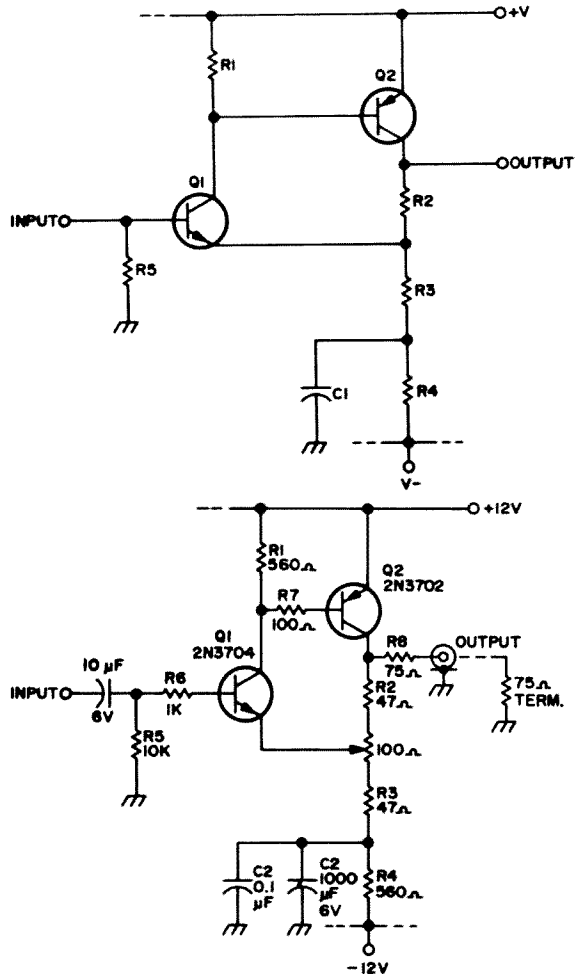
T.V. commercial killer, with no interconnecting wires. Use a flashlight to key relay. Circuit features low battery drain, auto reset. Courtesy Motorola construction projects.



2 transistor – 2 resistor equivalent of a programmable unijunction transistor (credit WB2VKU).



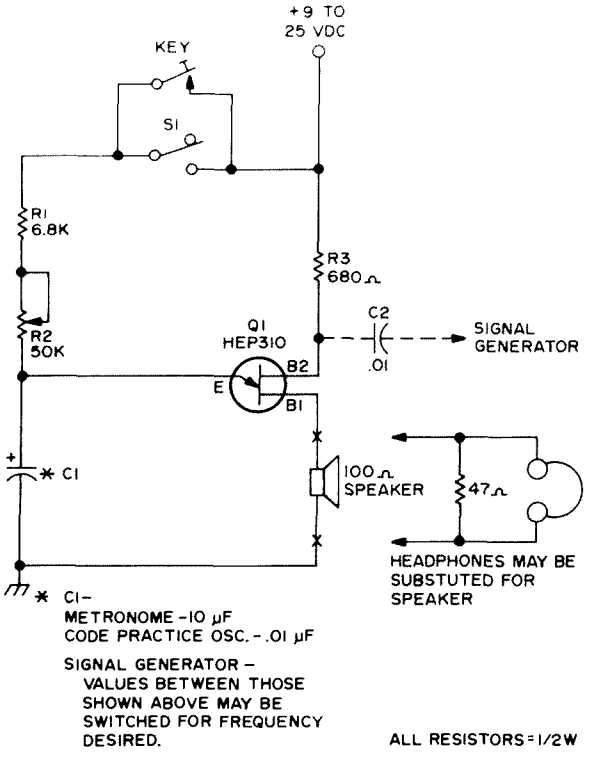
Burglar alarm (photoelectric) will actuate alarm when light beam is broken. Courtesy Motorola construction projects.



Crystal calibrator. This circuit gives symmetrical square waves out on 100, 50, 25 & 10 kHz. The frequency switch may be any distance from the totally shielded calibrator, as the lines have only dc levels. (Thanks to WØLMD)

Headlight operated garage door or light switch. Relay contact will close when light hits photodiode. Sensitivity adjustment is provided to prevent false triggering. Circuit courtesy of Motorola construction projects.

741 used as a high speed comparator. The output of this circuit varies from +12 to +2 volts and back with extremely fast rise and fall times. (Thanks to WØLMD)



Two transistor video amplifier, medium input impedance (5K) and low output impedance. Almost any small signal HF transistors will work in the circuit but ideally they should have a high cut-off frequency, reasonably high current gain and low output capacitance. In deciding on circuit values, the value of R3 should lie between about 22Ω and 100Ω and the value of R2 chosen to suit the gain required. Courtesy, Journal of BATC.

WORKED OHIO'S HIGHEST POINT AWARD

Sponsored by the Champaign–Logan County Amateur Radio Club. Will be issued for contacts made during field day and one of the VHF contests with the club station W8EBG; operating at Ohio's highest point located in Bellefontaine, Ohio. Only contacts made after June 1, 1972 will count. Send $1.00 or seven IRCs to cover cost of handling and mailing to: John L. Wentz, Box 102, West Liberty, Ohio 43357.

RADIO CLUB OF TACOMA HAM-FAIR will be August 19th and 20th at the Sportsmen's Chateau, 164th and Canyon Road, south of Tacoma. Activities will include contests, transmitter hunts, technical talks and displays, manufacturer's displays, auction, country store, beauty contest, and door prizes. Grand prize will be a solid-state 2 meter transceiver. Talk-in frequencies – 146.76 and 3965. Camping–$1.50 per night with electrical hookup. Advance registration will cost $5.00 and includes Saturday evening dinner, or $3.00 without dinner. Contact Emil Koth, K7GPK, 13616 10th Ave. East, Tacoma, Washington 98445, for registration forms or motel information.

ROCKFORD AMATEUR RADIO ASS'N The Bel-Rock Hamfest will be held August 20 at the Boone County Fairgrounds just north of Belvidere, Illinois on highway 76. Free coffee and donuts from 9:30 to 10:00 AM. There is no set-up fee and plenty of free parking is available. Talk-in on 146.94 MHz. Advance tickets are $1.00, $1.50 at the gate. For further information, contact: Lee Gehlausen, WA9WVY, 4610 Cayuga, Rockford, IL 61107.

SWAPFEST & PICNIC Sunday August 13, at the City Park in Levelland, Texas. Sponsored by the Northwest Texas Emergency Net and the Hockley County Amateur Radio Club. This event is for the entire family. Bring your own picnic basket. Free registration begins at 0900. Lunch at 1300. Swapping all day. Mobile talk-in frequency is the Net Frequency of 3950 kHz & 146.28–88, the Levelland Repeater (WB5EMR) or 146.34–94, through the Lubbock repeater.

7TH. ANNUAL MELBOURNE HAMFEST sponsored by the Platinum Coast A.R.S., will be held September 16th and 17th at the Melbourne Florida Civic Auditorium. Hours: 9 AM – 4 PM. Bring your gear to sell or trade. Plenty of paved parking. Registration $1.50 for each adult. Children free. For more information write Donald E. Sanders W4BWS, 1422 Virginia Drive, Melbourne, Florida 32935.

The annual Iowa 75 meter phone net will be held on the third Sunday in August, August 20, 1972, at Riverview Park in Marshalltown, Iowa. All amateurs and their families are cordially invited, or anyone interested in amateur radio. Each should bring a covered dish and his own service. Festivities will begin around noon. Prizes will be offered and a swap table will be available.

PRAIRIE DOG AMATEUR RADIO CLUB of South Dakota will hold its Summer 1972 picnic August 19th and 20th at the Isaac Walton League Club House on Lewis & Clark Lake west of Yankton, South Dakota. The festivities will begin at 1:00 PM Saturday with a talk-in on 3955 KHz and 146.94 MHz. There will be swap tables and a social get-together, transmitter hunt, films, tours of Electronics manufacturing plants and the Gavins Point Dam. Special interest sessions, programs for the ladies, bingo, and nearby swimming facilities promise to make this the event of the year. To pre-register, send $4.00 to P.D.A.R.C., PO Box 321, Yankton, South Dakota 57078.

The Shenandoah Valley Amateur Radio Club will hold their annual Hamfest in Winchester, Va. the weekend of August 5th and 6th.

A kick off Dinner will be held Saturday night, tickets $5.00 each. The Hamfest will begin Sunday at 10:00 AM at the Winchester National Guard Armory admission free. Registration for door prizes $1.00 each (no limit). For further information write for flier.

Shenandoah Valley Amateur Radio Club Inc. PO Box 139, Winchester, VA 22601.

The fourth annual Danville Hamfest will be held September 3 at Douglas Park. 146.94 will be monitored along with the Danville 22/82 and the Champaign–Danville 34/76 machines for talk-in traffic. $1 advance registration and $1.50 at the gate. For further information write Alan Woodrum WA9IAC, 1615 N. Bowman, Danville IL 61832.

The Zero-Beaters Annual Hamfest will be held Sunday, August 6, 1972 in the City Park at Washington Mo. Door prizes, free ham gear auction, free bingo for the ladies. Cake walk, free candy scramble for the kids.

The HAMFESTERS 38th Hamfest and Picnic will be held on Sunday, August 13, at the Santa Fe Park, Willow Springs, IL, southwest of Chicago. Exhibits for OM's and XYL's, famous swappers row. For information and tickets write to Joseph W. Poradyla, WA9IWU, 5701 S. California Ave. Chicago, IL 60629.

The Texas VHF-FM Society will hold its annual summer convention August 11, 12, and 13 at the Villa Capri Motor Hotel in Austin, Texas. Technical sessions, manufacturers' displays, door prizes, ladies activities. Call-In will be through the Austin 34-94 repeater. For more information write Gene Chapline, K5YFL, 2206 La Casa, Austin, TX 78704 or Larry Higgins, W5QMU, 2522 Old Hickory Trail, San Antonio, TX 78230.

The Burlington Amateur Radio Club, Inc, Burlington, Vermont, will sponsor the *1972 INTERNATIONAL FIELD DAY* at the Old Lantern, Charlotte, Vermont, on Sunday August 13, 1972.

Outstanding features include the Flea Market, Contests, Demonstrations, special events for the Ladies and the Rock Crowd. Refreshments available all day, excellent camping facilities on grounds, Saturday Nite Happy Hour from 6 to 12 PM. Come a few days early – talk in on 34-94, 22-82, 16-76, 28-88, all mountain-top machines (natch).

Registration $3.50 at the gate, $3.00 early bird. Write to: Al Snow, K1SLU, 12 Duchess Ave. S. Burlington, Vermont 05401. For more information contact IFD chairman Bob Hall, W1DQO, General Green Rd Shelburne, Vermont 05482. Phone (802) 985 – 2235.

On the 23rd and 24th of September, 1972, the North West Amateur Radio Conference is being held at the University of Lancaster, and they would like to extend a warm welcome to any American amateurs who will be in Britain at that time to attend the conference. Any interested amateur may write to Mr. Philip Jones, Department of Environmental Sciences, The University, Bailrigg, Lancaster, England.

BRAND NEW FREQ-SHIFT TTY MONITOR:
NAVY OCT-3: FM Receiver type, freq. range 1 to 26 MHz in 4 bands, cont. tuning. Crystal calib. Reads up to 1500 Hz deviation on built-in VTVM. Cost $1100.00 each! In original box, with instruct. book & cord, fob Mariposa, Cal. Min. signal needed: 15 mv. Shpg wt 110 lbs 49.50

HIGH-SENSITIVITY WIDE-BAND RECEIVER

W2NSD *(continued from page 70)*

tution and by-laws finally were mailed to the repeater groups. There is no hint yet as to how many groups will join the Association. The by-laws leave out more than they include, so some groups feel that in joining they are signing a blank check. No proposal has been made of expenses or goals for the NRA. When questioned about what the NRA could do for the repeater groups, the answer from Bob Waters was, "Don't ask what the Association can do for your group, just what your group can do for the Association." Some groups may want more than mere slogans to justify sending hard earned cash to Waters and Pugh in exchange for unstated goals and benefits.

The sudden resignation of Gary Hendrickson W3DTN, a highly respected Philadelphia FMer, as Secretary of the NRA immediately after the April meeting has not increased overall confidence in the Association.

. . .Wayne

W7DXX *(continued from page 160)*

all the reps of the manufacturers for a very good "Kass-vention." We'll see you there next year.

With both the Editor and Managing Editor of 73 avid DXers we decided to update the 73 hamshack. So, we replaced the Galaxy V, which has given years of faithful service, with the Kenwood Twins from Henry Radio. The trusty 3 element 20 meter beam, the one with the driven element 40 degrees off horizontal since the last snow storm, is being replaced by a 7 element 20 meter beam from Wilson Electronics. We have two other stations under construction. One is a Signal One CX7-A transceiver and the Alpha 70 amplifier. The other is our VHF station for 6 meters through 450. We will be using the Kenwood Twins for SSB and SSTV while the Signal One pair will be used for serious DXing both on SSB and CW. Other antennas include 7 elements on 15, 6 elements on 10, and a 4 element quad up 100 feet. The only problem we are going to have is putting out the magazine with all that new equipment to use.

I want to remind you again about the 73 DXpedition to Bajo Nuevo in November. We need a few more operators. If you can dig the idea of a DXpedition to a remote island, give me a call now. The cost will be around $500 per person. Also, the idea of DX is catching on. So, if your group has not written and called for information, do so now.

GDO COIL EXTENSION

A grid dipper is a great piece of test equipment and belongs wherever rf equipment is to be designed, constructed, or serviced. All writings on the subject seem to be prefaced with this comment, and I hesitate to break tradition. Now that the formalities are over, we will proceed with the subject matter.

Probably the one most inconvenient feature of all grid dip meters is the physical size of the instrument. This holds true for the two unit commercial models as well as the more common self-contained types. It is not so much that they are large but rather that the head will not always fit into the nooks and crannies which seem to be designed into most equipment. This situation will more than likely become more severe as integrated circuits come into more general use. At lower frequencies the coil assembly is usually long enough to reach to within shouting distance of the desired circuit, but as the frequency is increased the dipper coil shrinks to perhaps an inch protruding from the case. Try getting this even near a circuit buried 2 or 3 in. deep in a chassis and you will fully appreciate the magnitude of the problem.

There is a way of relieving the difficulty which requires neither a great deal of time nor expense. It is only necessary to put to use some basic theory which each of us was required to know in order to get a ham license. Required are perhaps a 3 ft length of small coax (RG 174/U), 6 in. of hookup wire and a ballpoint pen casing. The innards of the pen are removed, and the business end reamed slightly to accept the ends of a ½ in. diameter one turn link formed of hookup wire. Inside the barrel of the pen the ends are soldered to the coax, insulated, and cemented in place. The remaining wire is formed into a 2 turn link which fits snugly on the coil form of your grid dipper. This link is soldered to the opposite end of the coax and secured. Shrinkable tubing is perfect to cover the joint.

The next time you face this perplexing problem hold your head high and fear not. Merely slip the link over the coil form, place your probe so as to allow coupling into the desired circuit and proceed as usual. The only difference will be a more or less fixed load on the oscillator which doesn't affect its ability to indicate resonance. As always, best results are obtained with minimum coupling.

LED 7-SEGMENT DISPLAY

$4.95 Each

50-99 $4.75
100-999 $4.50
1000-70 $4.25

Large ¼" 7-segment LED readout similar to the popular MAN-1 but with improved brightness. Has left-hand decimal point. Fits in a DIP socket. Expected life: Over 100 Yrs. Regularly $12.95 in single Lots. These are BRAND NEW with full data sheet and 4-page MULTIPLEXING Application Note. Needs a 7447 for driver and ONE CURRENT-LIMITING RESISTOR PER SEGMENT. We can supply you with one or ten thousand FROM STOCK. Also available, ±1 OVERFLOW digit at the same prices. Mixing of Regular & Overflow digit allowed.

Package of 8, ¼W Limiting R's ..... .30¢

Incandescent Type of 7-segment display. With right-hand decimal point. Rated 8mA per segment at TTL supply of 5V. Design life of 50,000 hours. Needs a 7447 as a driver. In DIP Package. Each $3.25

MOLEX IC SOCKET PINS: Use these economical pins instead of soldering your IC'S to PC boards. Sold in continuous strips in multiples of 100 pins only.
100 for $1.00; 200 for $1.80; 300 for $2.60
400 for $3.40; 500 for $4.20; 600 for $5.00
700 for $5.80; 800 for $6.60; 900 for $7.40
1000 for $8.20. Each Additional 1000 $7.50

CERAMIC DISC CAPACITORS. Type 5GA-10000WVDC.

50 MEGAHERTZ DX

Paul Schuett WA6CPP
14472 Davis Road
Lodi CA 95240

After I worked some fine DX on six this summer, I have come up with some conclusions to pass along to other VHF devotees:

It would appear that the band is open more than most of us suspect. The problem is that there is nobody around working the openings. Of course, there are lots of people *listening* – it's just that they are all sitting in the shack minding their own business without even knowing about the opening. Since most openings come to light when you hear some exotic contact making some noise, take advantage of the situation and make some noise yourself – so the other fellow can hear you.

The easiest way is to engage in a local QSO, but orient your antennas in various directions. Now and then I'll talk with a fellow eight miles away. Aligning the antenna on a precise aximuth for such a distance is not necessary (the signals are so good that they come in on the noise blanker), so one of us aligns the antenna northeast; the other southeast. We cashed in on this with a breaker from Albuquerque.

There is no need to run out of things to talk about, unless you are particularly boring yourself. Talk about anything – the weather (yesterday, today, tomorrow); articles in the current issue of *73* (if he doesn't have it, you can read the article to him); discuss paragraphs from the FCC Manual (it is surprising the number of people who have forgotten some of the rules, or at least don't use them consistently); practice code, or anything else. We had a 3-way round table that had a break-in from Colorado in this manner. When the other guy hears you, he will come in.

It's a good idea to use your VOX instead of PTT, since you can hear the breaker and not ramble on for another five minutes or so and miss the DX because of changing conditions.

Nobody to talk to? Then make a lot of noise every ten minutes or so. A CQ only takes one line in the log, and you might turn up something fascinating. A fellow from Texas heard my CQ one morning – neither of us had any idea the band was open.

The call CQ DX is silly. If any DX stations hear, you can be sure they will answer; they are as anxious to work double-hop as you are. Most of these calls end up with a local contact anyway, so we are back making noise, which will be picked up on an opening.

Be a gentleman when the band is open. It is amazing how many nice guys turn into fiends with sharpened teeth when the band opens.

1. Don't tune your transmitter on the working frequency. Move up a way; things won't change that much, and the rest of us won't have to work through the carrier.
2. Don't send on top of someone except to give your call. One fellow was calling CQ in CW on top of a DX QSO, making it impossible to hear the stations' IDs.
3. Wait your turn in a pileup. If someone else is transmitting, bite your fingernails until he's through.
4. Don't ragchew in a pileup. Others are waiting. Remember the Golden Rule. Ragchew when it is apparent everybody around has checked in and you have a roundtable going.

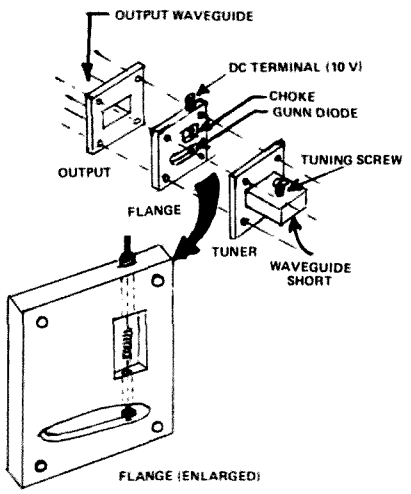
My first Ohio contact was marred by somebody hollering *INTERFERENCE INTERFERENCE INTERFERENCE . . .* " all the way through the 4-minute QSO. If this guy has a gripe, let him get on the air and tell me – I'll apologize. Meanwhile, like the rest of us, such a person should simply wait his turn, then give the desired station a call.

These suggestions have been successful in detecting elusive 6-meter openings. Let's not sit around listening – let's make some noise to let the DX know we're around.

. . .WA6CPP

Microwaves

The microwave news this month revolves around a letter sent by Dean Lewis (WA1NOQ) describing a series of commercially available Gunn Oscillators that appear to be cheap, cheap, cheap to make.



Before describing the Gunn oscillator, perhaps it would be of some interest to define exactly what we mean by a "Gunn" oscillator, or an "Impatt" oscillator. In fact, perhaps this is as good a time as any to make a small comparison between the microwave power generating diodes.

Bulk-Effect Diodes

The bulk-effect devices, made primarily from Gallium arsenide (GaAs) – because silicon and germanium won't work – are divided into two major categories: Gunn devices and limited supercharge accumulation (LSA) devices.

Gunn diodes, invented by J. B. Gunn of IBM in 1963, make use of the fact that a microwave oscillation will "ripple" through the entire semiconductor, much as a wave ripples across a swimming pool. Placing a voltage source across the diode causes these ripples to build up in amplitude until a large useful oscillation results. Voltages required for these devices are low (less than 15V) and are applied in the forward direction at currents up to one ampere. Output powers are from one watt at C band to ½ watt at K band. This is CW power.

LSA devices operate at lower frequencies (L band), higher voltages (up to 1 kV) and higher PULSE power output (2 kW), but do not operate in the CW mode. They were invented in 1967 by John Copeland of Bell Labs. Although they will work well into L-band, they are much more efficient at 8 GHz and above.

Avalanche Diodes

The avalanche devices make use of the fact that a reverse biased diode will reach a certain point where the current will increase astronomically for a small increase in reverse voltage. Some people call this the zenering point, and have noticed that diodes used as zeners generate noise. This "noise" is actually oscillation in the avalanche mode. There are two main modes of avalanche oscillation: Impatt and Trappat.

Impatt (IMPact Avalanche Transit Time) diodes operate on the principle of drift across the reverse biased junction. The time necessary for a particle to cross the junction is the so called transit time, and hence the name Impatt. These particles give rise to a negative resistance characteristic, and hence may be used as amplifiers or oscillators. Impatt devices operate from about 100 volts, and put out oscillator powers (CW) of one watt at S band, rising to 3 watts at X band. Pulse powers of 10 watts and X band and 5 watts at K band have been reported.

Trapatt (TRApped Plasma Avalanche Triggered Transit) diodes typically operate at 1/3 the frequency and 3 times the efficiency of IMpatt devices. In the trapatt, instead of the normal zenering action, a plasma is actually formed which supports the oscillation. CW output powers of 10 watts at 1 GHz and 2 watts at S band have been recorded.

Now, what Dean Lewis sent me was the method used by Fairchild and Microwave Associates to get powers of 50 milliwatts or so by means of a Gunn flange oscillator. These oscillators are meant for low power transmitters and local oscillators in superheterodyne receivers, and are quite adaptable to amateur X band. (For an excellent set of references see: *Electronics* magazine, 1 March 1971, the Fairchild data sheet, "Go(x)-100 Series X-band Gunn Flange" November 1970, and Gunn Diode Circuit Handbook by the Microwave Associates people, February 1971.) The machining necessary to build one of these devices is extremely simple (see sketch) and should be well within the capabilities of most microwave amateurs. The only trouble is the cost of the Gunn diodes. The industrial net price in onesey-twoseys is still around fifty bucks. Hey, how about some of you scroungers digging up a good, cheap source of Gunn diodes. If you dig up a few or a few hundred, I'll be glad to come up with an article for *73* with complete construction details for this particular diode. Until then.

MARS

Say, Oldtimer, do you remember the good old days when hams were a friendly, happy, extroverted bunch? Remember when you would attend a club meeting or a hamfest, and fellowship would be boiling over everywhere? When you knew every ham in the entire area, and all it took to get a coffee klatch going was a flip of a switch and a couple of words into the mike? Or when you would join a half-dozen friends on a Saturday morning to help some fellow put up a better or higher antenna? Do you recall being saddened when a fellow ham suffered an illness or a reverse, or rejoicing with him in his triumphs? Do you remember when becoming a ham made you a member of a very special fraternity with an informal motto of "All For One and One For All!"

Hello, young man! So you're a brand new ham, huh? Gee, I'll bet you are proud of that ticket! I notice you are sort of wandering around all alone – where are all your friends? Oh, you don't know any other hams except on the air! Do you wonder how you can break into that loudmouthed group having so much fun over there? You say you haven't been able to find any members of that happy, unselfish group that you have always heard made up the wonderful amateur radio fraternity?

Well, here s news for both of you! That fraternity which you so fervently seek is alive and doing well! You haven't been able to find it, simply because the particular type of ham that makes up the majority of such a group moved off the ham bands and is now operating as a member of the Military Affilitate Radio System – MARS!

It s not that these people are no longer hams – heaven forbid! They are still interested and active in all facets of ham radio – it s just that they have banded together with others who have similar interests, such as emergency communications, handling morale-type messages or phone patches from overseas military personnel, while at the same time learning to be rapid, efficient communicators, and having a ball on the military two meter repeaters!

The MARS membership includes teenagers and octogenarians, generals and privates, housewives and career girls – people from all walks and economic strata, bound together by a simple and sincere love of the MARS way of life. Nor is ours a static (sorry

50 MHz BAND

Bill Turner WAØABI
5 Chestnut Court
St. Peters MO 63376

VE4 "Morning After" has been joined by VE4 "Morning Prior," both from Winnipeg. Mike runs a modified SB-100. Welcome to 6, Mike – very pleased to be your first contact. Another VE4 heard for the first time from this QTH, is VE4YW.

VP5RS was worked immediately following the above contact with the beam still north. Signals were 5-9 in that direction, climbing to 25 over when the beam heading was optimized. Bob reported 550 contacts during the first 50 hours of operation. Arizona was the best DX to that time. This station made contact four of the first five days of operation, but signals never again approached the level of the first day. Thanks are due to Bob, Hoppy and Joe, as well as Bert and Tex of XE2XN and Allan 9P63N, for providing a little spice to what in this area, at least, was a rather blah contest week end. It is understood that Allen is to be a permanent fixture on Barbados, has a code wheel going, and may be expected to supply many interesting contacts in the future.

In connection with the above, split frequency operation is difficult for the transceiver owner, but there is a way around this if the rig is an SB-110 and there is another SB series rig in the shack (100–300–400). A short length of RG 174/U with a phono connector on one end is plugged into the LMO of the low band rig. The opposite end is connected to ground and the coax removed from the PC board pad which forms the junction of C38 and C39. After this installation it is possible to transceive on either LMO or operate split frequency using the internal LMO for receive and the low band LMO for transmit. Plugging the LMO into the crystal socket or the crystal oscillator grid and ground will not work. The rotation direction in the low band LMO is reversed, making it necessary to tune backwards (50.110 is .390 on the LMO dial.)

Numerous reports this month of KL7 contacts from the west and southwest – calls mentioned include KL7GFB, KL7GLL KL7HIF, and K7WXW/KL7. KL7DFE was also mentioned, but I suspect this is a misunderstanding. GFB and DFE sound very much alike. W4GDS finally QSO'ed a VE7. Bob needs only KH6 and KL7 for WAS. A number of California stations made the WAS list by contacting Art, WA1EXN, of Maine. Dave WA7JEI tells me he worked PY9GM on CW May 27th with 3-3-9/4-4-9 reports exhcanged. K4RNG, the only rebel from Ohio, is back on the air on a limited basis. I am sure friends all over the country wish Les a speedy and complete recovery. Six meters hasn't been the same without him. VE5US remains active with Doug doing most of the mic work. SYL is still around but deeply involved in other projects and not getting on the air much.

WAØTXV points out something which is obvious yet commonplace. Bob mentioned the practice of many working scatter during the contest to repeat the callsign of the called station over and over again after the effort to pass information was under way. As Bob says, "The station called knows his callsign, he wants to know yours." To this I would add the advisability of always *calling* on the same frequency (except in the case of QRM) during skip and scatter operation. All too often you hear a signal, get a portion of a callsign and are waiting for a QSO to end or for an opportune moment, only to have the signal disappear completely. After waiting for a period of time and not hearing anything further, you tune a little and discover the desired station up or down the band, then the whole procedure starts over. Tune if you will, but return to the same frequency to call and you will receive greater benefits for the hours spent.

On the 27th of May, while in QSO with WB4WXZ, "VUQ9W" joined in. His conversation, as relayed by Dave, consisted of the information that he was located on an island off Australia so small there was no callbook listing. The transmitter was 5 watts AM, solar battery powered because there was no source of commercial power available. It was stated that no QSL should be sent because there were only two mail deliveries per year. "John" was coming home in five months and would at that time contact all stations worked. Over the period of the next hour and a half or so, this station made numerous contacts with Florida stations, all strangely reporting 5-9 signals with their beams North. There must be a truly bright moon over the South Pacific! I trust the FCC noted the striking similarity in callsign to that of a well-known SSB hater in the north-central area.

Many thanks to those who included an SASE with their request for the list of TV manufacturers who supply TVI filters or help on problems related to 50 MHz operation. It has been a pleasure corresponding with many of you and I hope it has been worth while from your viewpoint, too. As always, activity reports, questions about 6 meters, TVI problems, and what have you, are welcome .

73 . . . WAØABI

DX WORD GAME

Buried in the maze below are the names of at least one hundred "good" DX countries. The names may read forward, backward, up, down and diagonally. A letter may be used in more than one name. How many can you find?

AMSAT NEWS

Michael Frye WB8LBP
640 Deauville Dr.
Dayton OH 45429

When Oscar 6 is launched many amateurs will want to process the Morse code telemetry data coming from the satellite. This can be done in a number of ways, first the code could be copied down by hand, but this is a tedious and time consuming process. A much better way is to use a Morse code to teletype converter. Then feed this into some form of home brew computer. With the proper program the data could be printed out in engineering form, such as volts, amps, degrees centigrade, etc. The results could then be sent to AMSAT (PO Box 27, Washington DC 20044) either by mail or over one of the HF radio links.

A-O-C when in orbit will be identified by a Morse beacon sending the letters HI (. . . . . .). This will precede and end each telemetry transmission, so that telemetry or CODESTORE information will be easily recognizable. The beacon will operate on 29.45 MHz within the repeater passband and will have an expected output of 0,2 watts.

CODESTORE

CODESTORE is a Morse code message storing system. It is a static shift register memory which is loaded from the ground through the AMSAT command network. After loading CODESTORE will repeat the same message until changed by ground command. CODESTORE will operate on the 29.45 MHz CW beacon. The memory length of A-O-C's CODESTORE is 768 bits, this is sufficient to permit storage of approximately 15 words in Morse code. The device is set to retransmit messages at 13.4 wpm, at this speed teletype characters can be recorded in CODESTORE and retransmitted to the ground at one-quarter standard 60 wpm teletype speed. To decode the teletype, one need only to tape record the message at 1-7/8 ips and play it into a teletype system at 7-1/2 ips. It will be entirely possible to store teletype messages up to 96 characters long by this method. A good example of the use of CODESTORE is shown in the following message: "orbit number 2109 had an ascending mode equatorial crossing at 1101GMT at 101 degrees west longitude. For later orbits add 115.113 minutes to the time and 27.781 degrees to the longitude per orbit." This would be read as: "ORBIT 2109 1101Z at 101W ADD 115.113 MIN AND 27R781 DEG PER ORBIT." In addition, emergency and request messages can also provide CODESTORE with many uses.

A Morse beacon operating on 435.10 MHz is also planned for A-O C. If it's completed in time it too will be used for telemetry or CODESTORE CW transmissions.

MARS *(continued from page 144)*

about that!) organization – our membership includes some of the finest technical brains to be found anywhere! Example: Third US Army MARS owns the world's entire supply of 2300 MHz moon-bounce operators – A4HHK and AA4RJ! Army MARS became operational in February, 1948. In order to keep the organization abreast of the times and state-of-the-art, periodic meetings and conferences are held at all levels where problems are outlined and solutions offered. Such a conference was recently held in Washington – and attended by *every* Command MARS Director in the United States, Europe, Asia and the Pacific!

If you are still not convinced that such an organization exists, that there is such camaraderie, fellowship and goodwill, just walk over to the MARS meeting being held at the next hamfest you attend – you will be welcomed! How can you become a part of this outstanding ham organization? Simply address a card, letter or radio message to:

THE TRAVELING HAM

OR, THERE'S MORE THAN ONE WAY TO GET A QSL CARD

Richard Musicer WB6URS
11970 Montana Avenue
Los Angeles, CA 90049

There is no need to tell those of you who travel overseas the advantages of being a ham. If you haven't yet been abroad, let it suffice to say that the enjoyment and education provided by any trip can be multiplied many times over by eye-ball QSOing with hams of other countries. However, there are important do's and don'ts when attempting to meet our foreign brethren. If you follow the following suggestions I've carefully outlined, your chances of a successful encounter will be much greater.

Once you have selected your itinerary, turn on the rig (no, not the one with the channel selector, the one with the VFO) about a month or two before departure. Look for hams in the countries you want to visit and tell them that you are planning a visit to their country on such and such date. Don't push them, but if they seem interested in meeting you, ask for their phone number, both at their home and where they work. Most will be very pleased at the suggestion. Keep in mind that no one is better qualified to suggest hotels and restaurants than these hams (but tell them what kind of accommodations you are used to). Also, you might ask them when their local radio clubs hold their meetings. Often they are weekly rather than monthly and you may wish to rearrange your itinerary slightly so that you can attend. This is a good way to meet many hams in a short time as well as an interesting way to hear their problems, which usually are very different from ours. (I don't remember one African club ever once mention TVI!) Say 73 and keep tuning – don't stop with one ham. It wouldn't be the first time to happen if you find your DX friend "out of town," etc. when you reach your destination.

After your suitcase is all packed (I hope you haven't shut it yet), here's what to throw in on top of your nicely folded coat. (If the XYL complains about the weight, take one of her five pairs of shoes out.) Your bible on the trip will be a recent foreign Callbook. (Nothing is more exasperating than to find that no one in your 1962 issue is to be found in the local phone directory when you arrive.) Throw in some of your nicer QSL cards and bring along some new commemorative U.S. stamps – you'd be surprised how many foreign hams collect them. Do not bring your ham rig. It's too big, too heavy, and your crummy portable dipole won't work anyway. Use your new DX friend's rig and beam when you visit his QTH. In addition, you'll never clear your equipment through customs in many countries, especially in Africa and the Far East. (In this article I won't tell you about the conversion from Drake transceiver to Sony FM Stereo where the plate load and tune become the bass and treble controls, and the mic gain turns into a balance control, etc. . .) Only schlepp parts if someone specifically asks you to.

If you already have phone numbers when you arrive, your job will be much easier. Just make the call (be patient with their phone service – it won't be like ours) and introduce yourself. However, please note that

(continued on page 148)

TRAVELLING HAM
(cont. from page 146)

just because the ham speaks English on the air is no indication that his family also speaks English. Ask for your friend by name or try a key word like "radio" to make yourself understood. When you do reach the ham (don't give up, it might take awhile) tell him about your good impressions of his country and suggest you get together at your hotel for a drink. Don't expect him to rush over to pick you up and take you immediately to his shack. If all you want to do is just get on the air, the best line to use is "I have a schedule with stateside in a half hour and would it be possible for us to give it a try?" (I'll never forget a certain ZS2 who drove about ninety miles per hour down the wrong side of the road to avoid the traffic so I could meet my sked.)

If you arrive somewhere and have no phone numbers, it s time to break out the Callbook. If there aren't too many hams in the city of the country you are in (like ZD5 or VR4), than a quick check with the names in the local phone book will probably be useful. Usually the latest listings, those at the end of the list, will be the newest and most active hams and the most receptive to visitors. Call them first. Those at the beginning of the list (ZX2AA, ZX2BB) are usually not very active, are old, and tired of visitors, but they may know the newer hams and how to reach them. In large cities, the local radio clubs are often listed and can give you phone numbers and addresses of hams. A good example of this is the WIA in the major cities in Australia. The Sydney branch is especially helpful in locating people. In more remote countries go to the local telecommunications office since they are usually the licensing authorities and often know who is active.

If all else fails, use your eyes. When you are in a taxi or on a tour bus, always look up. I have met many people both in large cities and in small VK9 villages by the old "bang-on-the-door" technique. These people are often the friendliest of all and will really go out of their way for you. The surprise factor is always fun, too.

There is a general rule to figure out how receptive hams in given countries will be to foreign visitors. When there are not many hams and a great number tourists, you can expect a lot of door slamming, not answering the phone, and disconnected doorbells. A good example of this case is Greece (Athens) or Fiji. If there are not many visitors, but lots of hams, expect the royal treatment. This applies to most of the larger African cities like Johannesburg and Salisbury. If there are very many hams and also a large number of visitors, you will still have an enjoyable time. This applies to Japan and Australia. In the case of countries where there are only one or two hams, but very few visitors (i.e., VR4, ZD5, VK9), you will probably enjoy yourself the most. Usually the hams in these places are the nicest you'll meet anywhere since they generally have much free time with little outside pressures or excitement which means that your arrival merits more attention. Needless to say, it's also more fun to get on the air from these places.

As a final hint, never expect anyone to do anything for you – you'll be much happier this way. And if nothing else, remember that you are the guest in any other country, and that when you travel you are your country's number one ambassador to the people you meet. Your actions ,courtesy, and politeness reflect on every one of your countrymen and if you act like you do in a pile-up, you'll hear your friend in the foreign, and not in the American phone band. Have a good time!

EVER HAVE A DREAM COME TRUE?

Sheldon K. Davis
98 Rex Avenue
Indiana, PA

Since Indiana, Pennsylvania is known as the "Christmas Tree Capital of the World" I have often thought how great it would be if there were a call available with the word TREE in it. Then along came the FCC with their special call signs.

I planted and nurtured the idea of the special event call of WT3REE in many club meetings – and suddenly it bore fruit! Helpers and club sponsorship were obtained.

The next hurdle was the FCC and their permission. Letters and phone calls established the fact that such special calls were getting harder to get. But – our request was a little unique – so permission to use it for four days in May to coincide with our local Christmas Tree Candlestick Festival.

Why a Christmas tree celebration in May? Easy! It's too cold in December. In addition, we are too busy cutting and shipping nearly a million plantation grown Christmas trees for shipment all over the world. In the merry month of May, the new growth on the evergreen trees resembles "candles" on the boughs. So the local leaders elect a Queen Evergreen, invite commercial exhibitors, local service clubs and others to get activities and ideas that will help separate the tourist from his hard earned buck.

It works too. About 20,000 people attend, eat hot dogs and pancakes, view stage shows and take tours of the "tree farms." About 400 campers used the event for a "camp-in."

Our local radio club borrowed a crank-up trailer from a dealer, scrounged up a big tent, set up rigs, made signs and handouts, put up antennas and were in operation WT3REE caper. Of course "little" things like hassles with the electric company about power. Oh they were willing, and even ran power to the top of an adjacent pole. But we couldn't get together with proper safe and acceptable material for the "bottom" of the pole. Ham ingenuity came through, though. All rigs and lights were operated from one little light socket in an unused ticket booth nearby (which permission was also hard to come by!) Antennas were strung up with the usual fun and havoc. They even worked – mostly!

Operators were easy to come by – at convenient times and with competition from a hamfest. Fortunately, a dedicated few braved the wee hours to make over 600 contacts in 24 states and Canada. Many listeners failed to see the TREE in the call WT3REE – but were happy to get the special contact anyway. Many more contacts might have been made but much rag-chewing went on both on CW and phone. But then again, that was the real purpose: to publicize the county and its tree industry!

Comes now the battle of the QSLs. The local Tourist Promotion Bureau is helping with the cost of the cards – but someone has to sit down and fill them out. A SASE was requested but some failed to get the message. We

(continued on page 150)

SSTV SCENE

It is really fascinating to see the programs some of the slow scan boys have worked up. Here one really has a chance to show originality. (Woe be unto us if K1YSD ever gets on slow scan!) Here's some thoughts to keep in mind when recording them when the band is dead and you have time. Try for the same audio level on all pictures. Clean the tape recorder heads (and de-magnetize if necessary) before starting to record. If you are using a battery operated recorder make sure fresh batteries are installed, or else, later when you install fresh batteries you'll pick up hum bars like in the June column picture. Also, make sure the slow scan system is properly calibrated; i.e., sync – 1200 Hz, black – 1500 and white – 2300 Hz. You might also check the 15 Hz horizontal sync rate (by reflecting a small amount of light from a lamp or VR tube onto the camera or phototube, or by pulling a ground on the video loose temporarily). Four vertical hum bars indicate 15 Hz. They tear to the right or left if the frequency is too high or too low. If you have Robot gear, turn the contrast to 9 o'clock and adjust the camera's controls to produce the best picture definition. This will assure maximum frequency deviation from the camera. A few minutes to check these few points will repay you ten-fold with quality pictures you'll enjoy sharing with other SSTV'ers for many times to come. And don't be afraid to splice pictures – they'll mate up quite easily with a little experience. Tapes not only provide a larger picture to time ratio, but they also free the camera and/or flying spot scanner for live relays.

I recently toured the radar facilities of an airport control tower, and a rather large ship. Those 14 and 16 inch P7 tubes really caught my eye. They also carry a few spares. A possible source of large screen P7s? Check around. . .they are more plentiful than the old 7290 slow scan vidicon.

Say, when are some of you YLs going to get on SSTV? If you think you rock pile-ups now with the feminine voice wait 'til you try slow scan and show yourself around. Gals are better to watch than receiver dials anytime! Come on – get "in" and on. . .SSTV.

The slow scan picture this month comes from Paulo, PY1DCB. This was sent from W6TEZ and was Paulo's first attempt at slow scan photography. Now he is in trouble with the XYL and wonders if anyone knows what magazine the pix was in. Sure that's not your next door neighbor, Paulo? Any rate, a very high resolution picture, with good gray scale and no QRM. You non-slow scanners – you are too close – hold the book at arm's length and look at the picture – don't read it.

Incidentally, a lot of fellows have been having a ball photographing pictures directly off the screen. This is most easily accomplished with a Polaroid camera (since the results can be seen immediately). Set the camera speed for a time exposure so when the shutter is opened it will stay open until you release it. A camera shop can make this modification if your camera doesn't have it. Openings of F4 or larger are sufficient for photographs with 4000 speed film. Place the camera squarely in front of the monitor (a tripod or stack of books may help) and open the shutter at a slow scan picture top, when you hear the vertical "blip," let the trace sweep down the screen its 8 seconds, then close it. (You did remove the yellow filter didn't you?) You will probably need to turn the brightness down, producing a dim picture on the screen, since the blue initial trace produces the picture on the film, and too bright a trace will "bloom" and not leave dark areas (washed out print). A close-up lens added to the camera will produce pictures almost as good as the ones on the screen, and will fill the photograph almost entirely. W4RKS made a nice monitor camera using an old Polaroid camera (lens swapped to 50mm, and refocused on film to produce close-ups) with a minibox bolted to the front. The minibox then fits onto the monitor firmly and the screen is viewed through a peep hole in the top. I believe Tectronics makes one like this, but the cost is around $300.

The other picture this month is from Franco, I1LCF and is a photo of the 1st prize of CQ Electtronica's slow scan contest, a Silver Thaler of Maria Theresa. It went to Don Miller, W9NTP. Congratulations Don!

Don't forget to drop me a card if you would like to see a U.S. Slow Scan contest this winter. These cards are our "poll" on how well the contest would be received.

. . .K4TWJ

EVER HAVE A DREAM COME TRUE?

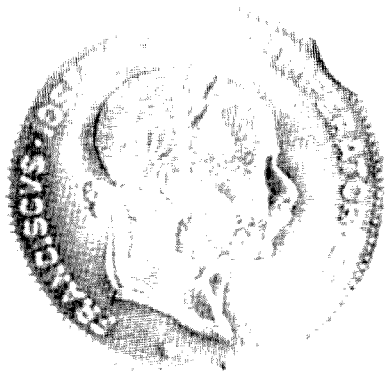
(continued from page 148)

hope to QSL 100% with all contacts. I hope that patience is a virtue of all hams (it is isn't it?).

The outstanding event was a visit from Ann Parks, the newly elected Queen Evergreen IX to the ham shack. She had never heard of ham radio so was duly impressed and surprised to find herself in conversation with WB4OWW down in St. Petersburg, Florida. She mentioned that she had an uncle down there. At this point, Jim, WB4OWW, spent much time in tracking down the phone number of the elusive uncle.

Finally the young lady jumped up and down with youthful joy and enthusiasm crying: "That's my Uncle Bob!"

And it sure was! The little Queen was able to tell her uncle of her election to Queen the night before. Both Jim and the local ops were proud and honored that we were able to make a little lady happy by her introduction to ham radio. Who knows: maybe a future YL op?



We made many mistakes – and many sins of omission! But we did make many contacts and helped many hams with a rare and exotic call sign. It is a great feeling to be on the other end of a pile-up.

One of the big – really big – outcomes was the cooperation and help from our own club members as well as assistance from the local VHF club. It was a great way of coordinating and consolidating club members and increasing club morale.

The local public relations – with help from the local news media – was also a plus to the event.

Yes, dreams do come true!

. . .Davis

LETTERS

Regarding the comment by K9MGX on page 4 of the June issue, for your information, a 73 dB acoustic level certainly is not near what is normally considered the point of ear damage, (although this is loud). In addition, this figure is meaningless unless you specify whether it is rms or peak. But, either way, a symphonic orchestra is well-capable of levels in excess of that figure in an acoustically "live" auditorium at 50 feet! Are you trying to contribute knowledge or ignorance?

Clyde Wade
Little Rock AR

I'm not the type of person to write letters, but I must write and congratulate you in respect to the articles on old radio pioneers and especially the article on lightning in the June issue (written by W2FEZ).

I'm fascinated and awed when reading these articles by Mr. William Hood. These are always the first articles I read, when I open the pages of a new issue. I have re-read many of his articles several times.

Please publish more of this type of article if possible.

W. Rush W8WAT
Tucson AZ

With the increase in use of Progress Line units, I thought I would mention a few pointers on converting them for 2 meter operation. In the 4ERC25B2 receivers both coils in the antenna transformer T301 should be padded with 4 pF ceramic tubular capacitors. The whole transformer can be removed by disconnecting the coax lead and unsoldering one lead of C5, which comes out of the bottom of the can and goes to Pin 1 of the 6AK5. Remove the 2 mounting screws from the bottom of the can and lift the transformer off the main chassis. Remove the 2 sub-assemblies from the can by taking out the screws on the sides. The padding capacitors can now be placed across each of the trimmers. If any of the rf trimmers (C305, 307, or 310) on the main chassis do not tune, they can also be padded with 4 pF. In the 4ERC25D2 receiver, only the antenna transformer T336 has to be padded (using the above procedure), as everything else will tune ok. In the 30 watt transmitter the final will have to be padded with a 4 pF capacitor soldered directly across the plate trimmer C157. The 50 watt and 80 watt transmitters generally don t require any padding at all.

Jim McCullough VE3CSO

I would like to thank you for publishing the General and Advanced Class License Guides. They enabled me to pass my exam.

Also, I believe that the June, 1972 issue is the best, or one of the best, you have ever printed.

Bob McCormick WB9HFD
Champaign IL

You've finally done it. After all those articles on FM, I have no choice but to go FM. The Gods have willed it, and who am I to argue with them? "Very good," say all you FMers out there. But here's the problem. Being a student, money's a little hard to come by, and when it does, it doesn't go to ham radio. So, if somebody would like to take my Swan 270B off of my hands, I'll use the money to go FM.

I really enjoy *73* but what happened to all of the chicks on the cover?? And Wayne is so crazy that I call him the Evel Knievel of ham radio. Any takers?

Scott Liebling WA3OXG
Pittsburgh PA

I read some time ago that RCA is phasing out the 2N398A, which has been popular for quite a while as a grid-block keying transistor. It was one of a very few cheap, high voltage, PNP transistors. Some of the gang may be interested to know that the 2N5415 has come on the market recently, and at just about the same price. There are a few differences to be aware of, however. The 5415 is a silicon transistor, and its maximum safe reverse bias on the base is 4V, versus 50V for the 2N398A. Its saturation voltage is higher, 2.5V instead of 0.35V. Thus, some circuits may need a little redesign before the substitution will work. On the other hand, the 2N5415 can switch 200V, which is nearly twice as great as the 2N398A. There is an NPN which is complementary to the 2N5415; the 2N3440.

John A. Carroll K6HKB/1
Malden MA 02148

I am not a life subscriber to any magazine, but if the May '72 issue is representative of your standards, you will have my life subscription when my current one expires.

Bill Winstead WA5TND
Philadelphia MS 39350

It would be appreciated if you would announce the formation of the "Purple Martin Net" which will be on 7.251 MHz every Sunday afternoon at 4 PM CST. The purpose of the net is to bring together those amateurs who are interested in this wonderful little bird. WA5MPQ is the NCS and I (W5BW) will be the alternate. Thank you for your attention.

Thomas W Braidwood W5BW
Alternate NCS—Purple Martin Net

You've got to be kidding! Asst. Ed.

Note Asst. Editor. *QST* and *Ham Radio* did not think so. See page 57 June *QST* and page 87 June *Ham Radio* – Now who is kidding. W5BW

Well, different strokes for different folks! Keith, Managing Editor.

Thought I'd QRX from work and drop you a line to tell you how pleased I am with my subscription to *73*. I find it not only interesting, but practical. It's well worth the money (no matter how long it takes to scrape it up).

Whilst down at the Dayton Hamfest, I thought I'd try a little experiment – I subscribed to every major ham mag while I was there and then waited to see who was "on their toes." Congratulations! I received my copy of *73* first. Next in order was *CQ QST* (renewal) and last (even though I had received a postcard saying my subscription would start soon) was *Ham Radio*.

Right now I m working about 11 hours a day at my present job: which leaves almost no time for amateur radio or anything else. But rest assured that I certainly will find time for each issue of *73*.

Keep plugging on Wayne, you're doing a great job!

Charles J. Rabley WA8RUO
Greenville OH

MORE K1YSD?

I was at my friend's house reading through the June issue *73* and happened to notice the K1YSD article. I read it. Two hours later, after reducing my laughing convulsions to short bursts of snickering, my friend's parents asked me to remove myself from the premises. While walking out the door I heard them mumble something like "moron" and "bad example." Now I guess I'll have to subscribe, since whenever I go over to his house, they lock the door and won't let me in.

Joe D. Rippel WB8IMG
Chagrin Falls OH

Step on the Klutz has to be the funniest thing written in. *73* Magazine since Bob, Bob, Bobbin' Along. C'mon Wayne, MORE, MORE!!

Gordon Bello WA1JWQ
Brookline MA

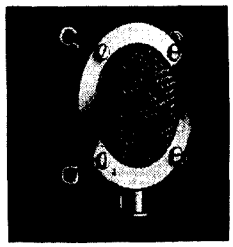
MORE LETTERS

This is in response to your letter of 22 March 1972 concerning amateur radio operations aboard U.S. Navy ships and the morale benefits afforded by such operations.

The morale benefits derived from shipboard amateur radio operations are well recognized. It is the policy of the Department of the Navy to support and encourage amateur radio activities, including those on board our ships. Shipboard amateur radio operations are generally allowed only during extended unclassified ship movements. This limitation is necessary in view of the requirements for communications security, as plain language communications to and from naval ships at sea have been determined to adversely affect our ships' operational security.

Amateur radio operations, as well as other means used for plain language communications to and from our ships at sea, have been a major concern to Fleet Commanders in Chief and to the Chief of Naval Operations from a security standpoint, particularly in times of crisis, and on a continuing basis in the western Pacific. From time to time it is necessary to curtail these operations to preclude the transmission of information over unauthorized circuits, which in the aggregate would be of value to a potential enemy. In area West of 160 degrees East Longitude have been curtailed consistently. Continued security difficulties in the Pacific area caused the Commander in Chief, U.S. Pacific Fleet, on February 1, 1969, to promulgate a directive curtailing afloat and airborne amateur radio operations, hospital ships excepted, within the Pacific Area until such time as active hostilities in that area have ceased. Since that time, the exception has been extended to include all ships on special unclassified operations such as the Apollo Prime Recovery ships.

The policies governing shipboard amateur radio operations are periodically reviewed. After a recent review, it was determined that, although the morale benefits derived from shipboard amateur radio operations are considered to be substantial, the communication security aspects are paramount. Therefore, the current policy will be continued.



In the event an article is published in your magazine, I would appreciate it if you would express my profound gratitude to the many amateur radio operators, including those affiliated with MARS, for the services they are providing our Navy people and their loved ones.

S.L. Gravely, Jr.
Rear Admiral, U.S. Navy
Director, Naval Communications
By direction of Chief of Naval Operations

Although I hated like fury to cut up my new *73* and my 1935 Rayo catalog, I just had to draw your attention to how little the venerable 104 mike has changed in 35 years – practically none!

From Ham Buerger ad, 1970: $25

From Astatic ad, 1935: $25.20

Odd how the pictures were taken from the same perspective and that the price is virtually the same. The only difference in the 1970 model apparently is the omission of the eyelets for ring suspension.

Bob Kuehn WØHKF
St. Paul MN 55118

How about a *73* oriented brain-teaser?

A group of chess playing hams planned to have a round robin chess tournament on the air. When the schedule was set up, 153 games were just too many. So they split into two equal groups and played two round robins, and the winners met in a play off. How many games did that arrangement take?

John Hunt
Pittsburgh PA 15236

ANS. A round robin takes n(n–1)/2 games.
So n)n–1)/2 = 153 given 18 men.
A 9 man round robin plays 36 games. Two of these plus the play off gives 36 + 36 + 1 = 73!

May 1 bring up one small point not mentioned in the aritcle "Easy Amps" in the May issue? This metering circuit monitors the current from or to the auto battery by measuring the voltage drop in the ground cable. This ground cable also is used in the starting motor circuit, and starting motors pull on the order of 200 amps when the starter has a normal load and much higher under abnormal conditions (the engine stalled in the middle of a traffic intersection on the hottest day of the year, and the air conditioner has been on all along!). One might wish to check this out before commiting a good meter. Of course, it will depend on what kind of overload the meter will take.

A similar current monitor scheme is used on many late model full size Chevrolets (especially the 1965 models) These particular models have the battery on the right, the alternator and regulator except starter motor current, is fed thru a number 12 or 10 red wire that goes across the top of the radiator frame. The factory option ammeter uses the voltage drop in this four foot wire. This method puzzled me for a while, a few years back, when I removed the idiot light cluster and replaced it with an option gauge cluster from a wrecked Impala Super Sport, and I could not find the meter shunt!

Sheldon Daitch WA4MZZ
Louisville GA

I have come up with an idea. Maybe it will or it won't work, but anyway, here it is. Since it is possible to transmit SSTV on the HF bands, why not have SSTV on FM subcarrier transmission on the VHF bands. It could be demodulated through a receiving setup similar to that of FM stereo. The main carrier could have a pilot signal or subcarrier of say 2 kHz, or possibly a subaudible frequency, or maybe a radio frequency in the VHF range, say of about 10 or 20 or 30 kHz. The only problem being that most FM signals are now being transmitted on narrowband deviation, and not wideband, in order to comply with "the-state-of-the-art" and modern receiver bandwidths. This system, of course, could be used on 1296, 220, or 450 MHz, or even 2 meters (in an unused portion of course).

Getting back to demodulation, however, the pilot signal would be the "television" video and the main "corner" the audio portion. This, of course, could be made narrowband by using a "pilot" signal or subcarrier of about 1 to 2 kHz, way below the standard deviation of 5 kHz, in use all over the country today. Is this possible? It could be, if some other hams who are interested could write to me at 50 South Porter St. Manchester, NH 03103. Any suggestions or comments would be welcome.

Michael J. Kane WA1PJG
Manchester NH

We had an odd situation here in NYC March 11th. I was on duty in the Empire State Building at altitude of 1000 ft and could see the snow coming down in a real blitz, not only nice white snow, but also big blue lightning flashes . . . on my way home I noticed that two cars with "burglar alarms" were blasting away. The guard at the exit of the building told me that they went off when "we had that big blue flash." So it seems these devices are capable of being triggered by external fields of extremely high amplitude, transient nature.

Neil W2OLU
NYC

Solid state alarm control systems can respond to transients caused by electronic fields such as lightning.

FOUNDATION for Amateur Radio Annual Hamfest, Sunday 22 October 1972 at Gaithersburg, Maryland Fairgrounds.

...AND MORE!

I always thought in your magazine and Repeater Bulletin, the "Letters" section was devoted to letters to you, but I find in Bulletin No. 5 a copy of a letter to *me* from Dick Morris, K1WZR complimenting our service. Thank you very much for including it ... it was really a surprise, although I noted on Dick's letter that he did send you a copy. To me, after putting in 10 and 12 hours daily, then several sleepless nights weekly due to ideas "buzzing around in my head" about how we might improve our service to customers and build our business – after all that, the sweetest sound in the world is a letter of appreciation like this one.

We're building our business on service, Wayne, and I feel much like a friend who was recently trying to "dream up" a spare-time business: He said "I know there are many people out there who are willing and anxious to spend money on some service I can provide – all I have to do is find out what it is." In our case, our decision is what we can offer the amateur that will make him decide to deal with us rather than our competitors, and the best answer we've found is service. We've been told as we grow, our ability to offer such fast personal service will decrease. I hope not, and am formulating plans to insure that it won't. As of now, however, we *can and do* provide it, and letters like Dick's are an excellent way to get this message over to the amateurs, and we do deeply appreciate your help in this rather unusual way!

HOME AND AUTO BURGLAR ALARMS

In designing these circuits, the following three points were kept in mind: One, reliability; two, simplicity; and three, low cost.

The home burglar alarm uses magnetic reed switches (normally open). They are composed of two halves. One half is a magnet, the other half is a switch. One complete unit is required for each door and window. The magnet half is embedded in the top of the door or window, the switch half is embedded in the top of the door or window jamb, with connecting wires.

The embedding is done with a router. The relay is a single-pole contact with a 12V coil. The contact rating is determined by the amount of current necessary to activate the alarm (horn or bell). As will be noted from the diagrams, no current flows until one of the switches is activated. When this takes place, the relay closes, thus completing its own electrical path, so even if doors or windows are closed after opening, the alarm will keep going. The only way it can be stopped is by either the key switch or the battery running down. Naturally, a time relay may be used to shut off the circuit after a predetermined time. However, I prefer continuous operation. Battery life is normal shelf life unless the system is activated.

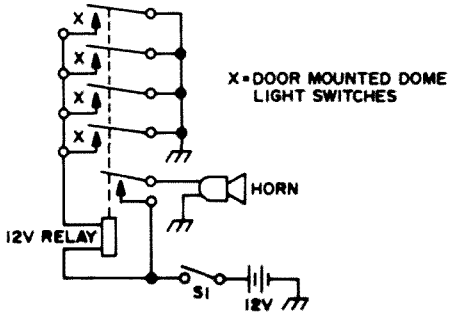

Fig. 1. Auto alarm.

The automobile alarm uses the existing dome light switches which are embedded in the door jambs, and in no way alters dome light function. Also, the alarm horn is the existing horn. The key switch to activate or deactivate the system is placed in some inconspicuous place on the body of the car. If the hood is to be protected, use a magnetic reed switch or a mechanical switch, so that when the hood is closed, the switch is open. The wire from the battery to the relay contacts and from the contacts to the horn should be at least #10 wire.

I have a little bad news for some Technicians who use repeaters. Several citations have been issued to users of the Los Angeles WB6ZDI machine which uses 146.610 as the input and 147.330 as the output. Both Richard Burton, WB6JAC, and Carl Siminow, WA6JOW were cited for "OPERATING ON A FREQUENCY NOT AUTHORIZED FOR TECHNICIAN CLASS LICENSE. NON-COMPLIANCE WITH SECTION 97.7 (c) OF THE FCC RULES AND REGULATIONS." I was under the impression that a Technician could legally be transmitted out of his segment if the licensee of the repeater had a General Class license or higher. Not so says the FCC. I had a very interesting telephone conversation with Mr. Jack W. Bazhaw, K6FLO who is the Engineer in-Charge of the Santa Ana, California FCC Monitoring Post. Mr. Bazhaw, himself a repeater user. (W6FNO) explained that the FCC considers it illegal for a Technician Class licensee to be retransmitted out of his frequency authorization. The important point to note here is that the FCC puts the burden of responsibility on the Technician and not the repeater owner or licensee. I know of several repeaters around the country with an output above 147 MHz. I know there are many Technicians innocently using these machines and not aware of the Commission's decision. Hopefully, Docket 18803 will solve this and other problems. However, until 18803 is acted on, remember, it is illegal for a Technician to use a repeater with an output above 147 MHz. I realize some of you are asking, "What if the Technician does not realize he is being retransmitted out of the band?" I know there are a few areas of the country where, because of several repeaters using common inputs, you can transmit and never know on how many frequencies you are being repeated. I am afraid that there is just no way you can be sure, especially if you have a good installation for a base station and operate during the frequent band openings on two meters.

While we are awaiting the outcome of Docket 18803, the Europeans have made their decisions and rule making for repeaters. Their new rules and regs parallel those of the United States, in many ways. I am told the delegation used areas of our country where the repeater operation is organized for their guide. They used southern California to show how not to do it. I greatly admire the southern California group. They were, for the most part, responsible for the rapid growth and acceptance of FM and repeaters. However, times are changing. The entire country, with the exception of the southern California area has organized and standardized. Without ruffling any feathers, I do urge the repeater owners and operators in that area to follow the trend of the country and now Europe.

Back to the FCC, on another subject, the Commission has authorized U.S. amateurs to communicate with XV5AC near Saigon. So, another restricted country is back on the OK list.

I was invited down to Philadelphia on June 17 for the first annual Kassvention, along with such people as Bob Cushman of Cushcraft, Sam Rainwater for Henry, Doug Horner from Drake, and many others. Everyone had a great time. Kass has, in my opinion, one of the finest facilities around. Just about anything needed from complete stations to those hard to get parts can be found at Kass. Thanks to Vince and Al of Kass and

EDITORIAL BY WAYNE GREEN

SLOW SCAN PROGRAMS

It is one thing to get on the air with slow scan and it is another to come to terms with this new media. You can't use it for very long the same way that you use your phone rig. The problem is the same one that has croppered commercial television – the medium eats up material at a rapid rate.

If you are careful to always make new contacts you have no problem. On the first go round you can get away with sitting there smiling into the camera, flashing your QSL, or a few hastily made posters. From there you can work up some photographs of the wife, children, the shack, house . . . but where do you go from there?

The "professionals" at the game have long since hooked up a good cassette tape recorder to their slow scan system and settled for putting their programs on tapes. As you quickly discover, it will keep you hopping if you have to change flash cards every few frames, swing the camera around and focus it on you or the shack, change your lighting, etc. You will do better to set up your programs similar to the way a television director does the job. Yes, I used to be a TV director, so I can speak with authority.

The first contact should be relatively simple, and consist of a few pictures of you smiling into the camera, a couple of the shack, one of the wife, and a QSL. In practice you'll need two different programs for the first contact, one for working stronger stations and one for weak DX work through QRM. With the weak ones all you really need is a very simple QSL with your call and location on it, probably in big white letters on black.

The second time around you may want to be able to spring something more complicated on your contact. You might do a program showing some of your interests. If you fly, drive an unusual car, have a boat, cameras, or whatever, these are all good grist for the television mill. If you are living in an area of special interest you could shoot some frames showing details about that. Don't forget your kids. You can even hoke up some shots of your baby sitting at the rig or with a mike on a tricycle – you know. The family dog is good for one DX Hound shot.

If you make any trips, keep your slow scan in mind and take some black and white pictures which you can enlarge and put on slow scan tape.

The fact is that there are unlimited possibilities for slow scan programs. I would like to be able to present some of the more interesting ones in the pages of 73. Please get your cameras and cassette recorders set up and, when you come across an interesting program, tape it and send in the pictures so we can pass them along to the readers.

By the way, it is interesting to note that the new slow scan system that has just been announced by Linear Systems (SBE) has a cassette recorder built right into the monitor! This is a logical development. We've been promised one of the new SBE systems and hope to have some interesting news of how it works for you.

The J&R unit has promise too. We did have a chance to try out an early test model for a couple of weeks just before the Dayton Hamvention and were impressed. J&R is making some changes and improvements on the unit and we expect to be able to give you full details and our evaluation before the end of the year. The J&R has a slightly smaller monitor screen than the Robot and there were some slight problems with triggering the vertical scan, but the tuning indicator was most helpful. A good deal of the time you discover a slow scan signal by virtue of the picture being sent and, unless you have a terrific ear or a tuning indicator, you have a tough time getting the picture tuned in right. Once you hear the voice you can zero in just fine, but by then you've missed a lot of pictures.

Most of the slow scan articles so far have been steeped heavily in the technical aspects of the mode. Now that Robot, with SBE and J&R close behind, has reduced much of the technical end to black box (grey, actually) practicality, perhaps we need more information on applications, techniques, use, and such. We certainly do need info on getting the units into tune. It can be most frustrating to the average black box (even if it is grey) user to plug in his camera and monitor only to be told that his contrast or something isn't set right. What to do?

Slow scan is presently limited to the Extra and Advanced segments of the lower bands. Is this a reasonable limitation? Is the use of this new mode part of the reward for getting a higher class license? Is this part of the incentive? Let's have some individual or group out there petition for slow scan on all phone frequencies and see what is what.

The band limitations right now for slow scan are 3.8–3.9, 7.2–7.25, 14.2–14.275, 21.25–21.35, and 28.5–29.7 MHz on the lower bands. All of the phone frequencies above that are open for slow scan. What do you think?

HIGHER POSTAGE

A recent publishing industry magazine revealed that the reason for the postage increases during the last few years has been an end motive of stopping the mail delivery of all magazines and making them be purchased on the newsstands.

When you consider the amount that postage for second class mailing has gone up, this seems not unlikely. It is interesting to note that recent increases have been even steeper than those in the past. The July increase was almost a 50% jump in postage rates for mailing magazines. As near as we can estimate this will make it necessary to increase the yearly subscription rate by a minimum of a dollar – and more probably two! And when you consider that there is no end in sight for this, it is frightening.

The cost of mailing a single issue of 73 has increased over 300% in the few years we have been publishing. Inflation has been serious, but nothing to match that increase.

The post office could, if they wanted, get the cost of handling magazines down to a fraction of today's costs. When you consider the number of magazines that they handle, this is an obvious candidate for automation. Yes, I know that the post office has tried automation and failed miserably – but perhaps magazines could be a different deal.

If the P.O. had a special price for magazines which would fit their automated sorting equipment, the magazines would quickly come around and make the magazines to fit the automation. I should think that something about the size of 73 would go through automatic address readers and sorters quite easily. Larger magazines might tend to bend and fold. Magnetic ink on the addresses would simplify the sorting, allowing machines to decipher the zip codes and speed them in the right directions.

With all magazines the same size, except for thickness, there would be

little difficulty in having the handling of them almost completely automatic. It is people that make for higher costs of handling mail . . . and for slower handling. A magazine sorting machine could zip through thousands of magazines an hour . . . maybe tens of thousands. If the addresses were put on the spine of the magazine they could be "read" and sorted as they moved along.

Unless something like that comes about the post office will eventually be able to force magazines out of business except for newsstand circulation.

EXPO 72

While not the dud of Expo 71, this is still not a hamfest to drag in the troops in quantities. Much of the problems facing the committee running the hamfest this year were the results of gross exaggerations made by last year's committee which resulted in enough resentment on the part of many exhibitors to keep them away in 72.

As an exhibitor in 71 it seemed to me that the 10,000 or was it 50,000 promised was in actuality a few dozen. This year they soft-pedaled the promises and few of the exhibitors were disappointed.

Expo is, by large, an FM affair. A few CB groups turned out to display, but most of those attending were FMers. CQ wisely decided not to support the hamfest this year. Ham Radio was there with a whole bunch of free subscriptions. QST did not support the hamfest either.

One of the most exciting exhibits was the two meter synthesizer at the RP Electronics booth. This gadget had the FMers waving their arms in anticipation. The prototype looked good. It had a numerical readout for the transmitter channel and the receiver was automatically 600 kHz higher. Thus all you had to do was set it for 146.16 and it would receive on 146.76 . . . etc. They are working on a model with separate dials – but since almost all repeaters today are 600 kHz spaced, by the time they get the second unit in production it may not be needed.

General Aviation was there showing off their new transceivers . . . and the pileups around the booth were as heavy as any we saw at the hamfest. Thirty watts and ten channels for only $250 may be a popular combination.

The Clegg 27A, now being delivered at long last, was on display and was a focal point of interest. It was an FM hamfest, for sure. Keith W7DXX and I manned the 73 booth. We took along a 27A for our own use in the rented car, this being a better-than-average solution to the need for a lot of new channels. The Chicago repeater situation is not all that might be hoped – with just one major repeater serving an area with thousands of amateurs. This is not to in any way put down the service provided by WA9ORC – a truly remarkable machine, with ears everywhere and fantastic coverage. But, when you consider that there are about twenty repeaters ready for instant use from Peterborough, the three or four Chicago channels seem scant.

Erickson Communications had an interesting booth, filled with nice Standard radios and Tempo amplifiers. Fred Deeg K6AEH was there from Standard, thus winning the prize for the manufacturer who came the furthest for the hamfest. Jim O'Connell W9JZK, the prexy of Erickson, asked around for a competing two meter amplifier to put alongside the Tempo so customers could see the incredible difference in design and construction between the two . . . he located one which a local amateur was anxious to dump and put it next to the comparable (and lower priced) Tempo amplifier. It wasn't too long before the word got around and the other manufacturer came by for a look. He looked . . . and looked . . . and got red in the face. "How much do you want for that?" he asked. "Oh, forty dollars will take it," said Jim – two twenties were in his hand immediately and off went the amplifier. "Don't you want the screws for the bottom?" called Jim after he stormed off.

One of the interesting items unveiled at Expo was the new Standard tone burst encoder – five channels – and designed to plug right into the back of the 826's. It is designed to mount right under the transceiver, matching it, and the price is about $80.

Another crowd gatherer was the line of rf preamplifiers shown by Crawford Electronics. The 146 MHz unit has been out for some time and has earned a very nice reputation. The new units for 220 and 450 MHz look promising.

Few HT-220 owners have not looked with desire at the very flat touchtone unit which has been available to selected cognoscenti . . they are now coming out for the hoi polloi (us). Waller Electronics in Maryland has a complete unit available for about $55 which mounts on the 220, making it about 1/8" thicker. A larger version is also available for $35 ready to connect to other hand and mobile units . . . $30 in kit form. The very small size of these units is made possible by the use of a flat touchtone pad and a tiny IC to generate the tones. Watch for ads from Waller – and an article in 73.

The little 73 FM Log Books (25¢) sold out almost in minutes when "Ev" Everett of the FCC turned up, smiling. I don't think anyone has ever seen fellows wandering around a hamfest before, making logging motions after every portable contact – and the walkie 2m FM transceivers were everywhere – in great profusion. All you had to do was say "BOO" on 94 and your voice would echo back to you from hundreds of belts.

If the Chicago group keeps up the good work, this event could turn into a major yearly hamfest.

AUTOMATIC ID

The FCC seems to be moving along inexorably toward a system of automatic identification for all transmitters. Though this may be another big step toward Big Brother, still it may have enough advantages to offset any "invasion" of privacy that might bother us.

The basic system is simple – build a miniature IC identification unit into each transmitter so it can be identified whenever it comes on the air. This would be built in by the factory on commercially made gear – would be permanently installed and supposedly tamper-proof. The module would transmit a binary blip every time the transmitter was operated and repeat it every 30 seconds. The whole process would take about 5 milliseconds, so it wouldn't be likely to bother anyone much.

Early estimates are that the identifier might cost about $10 at the manufacturers level, which might add about $30 to the ham price for a rig – but experience with IC costs indicates that competition and mass production would probably cut that substantially, probably not adding more than about $10 at the most to the end price.

Obviously the FCC problems with monitoring the many services it runs herd on will be simplified. Monitoring stations need a computer to catch the identification and compare it with license information in the memory. The problems they have with marine operators, police, business and even CB could be quickly eliminated. Rigs without identifiers could be quickly spotted and put off the air. Illegal CB contacts certainly would stop once identification became instant and positive.

As far as amateur radio is concerned, this could be the ticket to getting rid of the antiquated rule requiring us to log all transmissions. And think how fast contacts could be made if it only took 5 milliseconds to call CQ! And how great it would be to have an immediate identification of

that DXpedition that forgets for hours on end to mention their call.

I can hear it now. "Blip?" "Blip – – blip!" "QSL."

"Blip?"

SSTV in QRM

Most of the slow scan pictures in the magazines have been taken under ideal conditions. The conditions on 14,230 are not invariably ideal. The result is that some of your DX slow scan contacts may be touch and go, with the DX station having to send quite a few frames before one is received that can be deciphered. My first VK contact was through quite a lot of interference and it took about twenty frames before I got one that came through well enough to call it a contact. The picture above shows what happens when the QRM begins to build up on the slow scan channel . . . this was received by K3SLJ from me on Navassa. You can read it, but that's about all.

INCENTIVES

In a recent letter to an amateur Prose Walker of the FCC Amateur Division mentioned that he was taking steps to find out why 95% of the amateurs have not obtained the Extra Class license. I am one of the 95% and perhaps my own reasons are not entirely irrelevant.

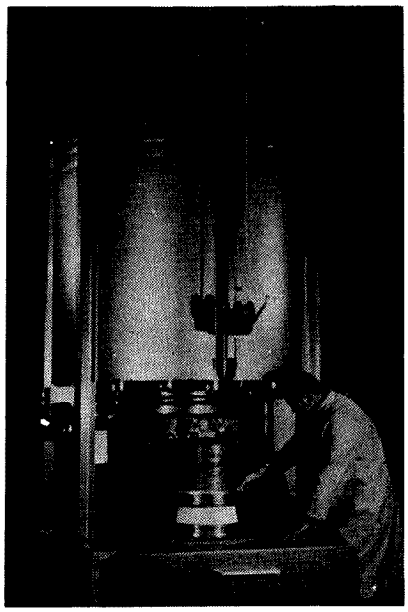
The technical aspect of the license exam looks like a breeze. I am sure that with one or two readings of our Extra Class Study Guide that I would have little trouble getting through the written part. But the code is something else.

I do miss not being able to operate on the low end of the 75m band. That was where I used to hang out, looking for DX and keeping in touch with the gang that hangs out in those waters. Once the band was taken away from me I stopped using 75m almost entirely. But I will be damned if the FCC is going to punish me into taking the Extra Class license – and I will continue to resist, even if they force me up to 1200 MHz.

If the FCC had offered me anything at all in the way of an incentive to get an Extra license I probably would have been right in there, but you do not get action from me by whipping me into submission. This was my reason for protesting the whole idea when the ARRL first suggested it – and again when they petitioned the FCC. I want some kind of reward, not just a cessation of punishment.

My interests in amateur radio are wide – very wide. I enjoy FM, repeaters, RTTY, SSTV, DXing, rag chewing, DXpeditions, and so on. One thing that I don't care for is CW. I am quite sure that if CW was voluntary I would be right in there, getting a big kick out of it. But it isn't voluntary at all – it is compulsory, and the result of that is to get my back up again. The technical exam for some reason makes sense to me – I can understand why that is needed to screen out people who want the amateur license. I don't understand what the relevancy of being able to send and receive code has to do with the matter. I have been an amateur for almost 35 years now and have used voice, RTTY and slow scan signals, but my use of code has been minimal – so why should I have to develop a useless skill of 20 wpm code for a higher phone license? Baloney!

You may wish to call me lazy – and I admit that I am lazy – very lazy when it comes to things that are a complete waste of my time and energy. I will work like hell for something that I want and seems reasonable. How many people are basically different about being lazy?



The FCC has turned me off for the time being on 75m and 15m by taking away some of my phone frequencies – but I'm still hanging in there on the other bands. If they come along and dump on me some more I will probably retreat. The psychology is so simple that it is incredible that it is so totally ignored by the FCC – if you want people to go along with you you offer rewards, not punishment.

FM EMERGENCY CHANNEL?

A few of the curmudgeon old timer FMers, inculcated with commercial practices, have been grumbling that repeaters are for emergencies and shouldn't be used for rag chewing. Pish tush and nonsense. If there are enough repeaters in the area to permit rag chewing, then why not? If there are not enough repeaters, how about setting up some more?

There is something to be said about the problem of trying to break in on a pair of inveterate rag chewers. There is a lot to be said. But what is the use of trying to say it when you can't get a word in edgewise? May I suggest an emergency priority input channel? This would allow the gabbers to talk away, repeating themselves as much as they like, pouring forth clichés and trivia, but would still enable the repeater to be used instantly in case of emergency. How about a national panic channel on, say, 145.74 MHz?

A priority channel would certainly be helpful. It would have been nice the other day when I was zipping along the interstate and came across an accident. Sensing the chance to use amateur radio for public service I got a message from the dazed woman who has been driving and wanted her father and husband to know that she and the children were on their way to the hospital. You guessed it, before I could break through on the nearest repeater I was able to phone the message from a gas station. Rats.

WA1KGO Increases Power

Alerted by several ops monitoring the 19–79 repeater that WA1KGQ in Vernon (CT) is stepping up its power in a possible first step of an escalation to take over the 79 channel, the engineering staff on Pack Monadnock swung into two shifts a day to get the new amplifier for KGQ in operation. Here you can see the new final for KGQ being tuned up on 79 by the 73 Technical Editor. Note the nice diplexer built into the plate tank circuit.

SABOTAGE?

One of our readers ran across a weirdie – he bought a piece of surplus which arrived in the original unopened package and, upon close examination, he found that a strategic wire had been cut down deep inside, rendering the unit unworkable. Since the unit had obviously never even been opened by the military, this was a factory "prank." Has anyone else run across anything like this? . . .Wayne

SSTV SCENE

A lot of newcomers have asked about operating procedures and typical picture transmissions. So, first off this month I would like to pass along some ideas to new SSTVers.

Generally most of the gang calls CQ on slow scan for a few frames, interspersed with audio IDs like "K4TWJ calling CQ on Slow Scan TV" a couple of times, then maybe another frame or two of CQ before standing by. This way your video will be noticed if perchance your audio isn't. Pictures you will probably want to record and have ready to transmit often will be pictures of yourself, the XYL, rig (with close-ups of home brew gear) and maybe your city. Plus plenty of IDs. These pictures when recorded on tapes, marked with leader tape as to their content (you can write on paper leader with a ball point pen) make positive transmission of a given picture a snap, while leaving the camera free for candid shots or "instant QSLs" (those menu boards with lettering or blank sheets for the flying spot scanner). Try to briefly explain complex pictures before transmitting them so the other fellow will know who or what you are showing. Then two or three frames of each picture are usually enough for good copy without getting dull. There is usually some of the SSTV group hanging around 14.230 kHz and most of them acknowledge breakers immediately since a group means more pictures and information in a shorter length of time. (And if you are not good friends then, you soon will be).

An item which is just starting to catch on in slow scan popularity is continuous tape loops. W1VRK mentioned this briefly in his recent QST article. Tape loops are ideal for CQs and IDs and are easy to make and use. Just mark a frame of your ID immediately before the vertical pulse (that 1200 Hz "blip") with a grease pencil on the outside of the tape. Let the tape run for 8 seconds (120 lines) and mark it again at the picture bottom (right before the next 1200 Hz vertical pulse). Now splice out the marked frame and splice the frame together to make a loop with the beginning and end of the frame butted together. Drop this loop into the tape recorder, and let the slack just dangle over the side – no spacers, rollers, or reels necessary. Since the end of the frame is spliced to the beginning the loop will play over and over across the tape recorder heads until you stop the tape. Marking the direction of feed and tape content with a grease pen will help if you make up a group of different loops. And hang the loops close by – they'll probably get quite a lot of use.

It is good to see the W7ABW/W7FEN scope adapter in the 1972 ARRL Handbook. This is still one of the least expensive and quickest ways to get on SSTV, and should inspire quite a few to put those old scopes to use as a monitor. Speaking of that, have you noticed how those old scopes are being snapped up at hamfests? It will not be long before scopes are scarce and prices up with the swing to SSTV. (P-7 cathode ray tubes have already started to climb!)

One who is making news with SSTV on 6 meters (and above) is WA1NNW. Ed has worked over 5 states and shooting for WAS/SSTV on six, using a 'scope adapter and W9NTP sampling cameras. He's another one planning SSTV use of the coming satellite. Need Massachusetts on six? Get in touch with him.

Well, I may be taking my life in my hands, but I have another item to pass along this month. Gray scale tapes. These tapes are ideal for setting up and aligning slow scan gear. They consist of 7 shades of gray, and run at 3¾ IPS, 1/2 track. I have approximately 50 of these on 3" reels, and when these run out, I'll cut you a few frames off my 7" reel, and you can splice it into a loop, like I mentioned in the first of this article. Send me a SASE, box, or manila envelope (preferably with a 3" reel of tape inside so I can just swap or dub). If I'm out of the 3" reels I'll return yours and send you some frames to splice into loops.

That's it for this month, be "seeing" you on 14.230.

. . .K4TWJ

* * *

THE COMPLETE SSTV ROSTER?

The chaps at Robot have published their list of slow scanners, and it is a formidable one, with operators in 52 countries listed. Like a repeater list, there is no way to have such a list complete and accurate – even an effort such as the one by Robot is difficult.

It would be nice to be able to publish an up-to-date list of the SSTVers, but I suspect that it would take more time than I could handle. Of course, if there is someone out there who digs slow scan and who is retired or has a lot of time available, perhaps he (or she?) might like to be custodian of The List? Can you ask for a more rewarding and lower paying job?

If someone would like to tackle this list I think that 73 can help. I had in mind asking via 73 for slow scanners to sit down and make a list of all the slow scan stations (two way) that they had worked. Even if only about 10% of the active slow scanners sent in the list the result would contain virtually every active TVer. For that matter, if we got a list of everyone worked by about a half dozen of the most avid scanners we would probably have 99% accuracy. Any takers?

. . .Wayne

* * *

Here are some recently submitted slow scan pictures – all received over the air and photographed from the Robot monitor.

W8YEK has his Polaroid camera ready whenever something unusual pops up on slow scan. Here is a recent picture Gene picked up from a ZS3 in South West Africa.

Postage stamp received by K4PRT. This shows you what can be done with the Nikon 55mm lens.

50 MHz BAND

Bill Turner WAØABI
5 Chestnut Court
St. Peters MO 63376

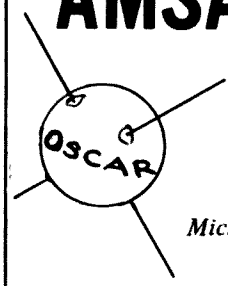
From most reports band conditions for the June VHF contest were rotten and at first this writer was inclined to agree but after counting all sections worked and heard it really wasn't all that bad. From this area of the midwest openings all though the summer E season were frequent and well distributed as to direction. It seemed that there was a tendency to open an area for a few minutes, close suddenly, only to open to an entirely different area moments later. On the air conversations and correspondence with numerous observers from Maine to Arizona and British Columbia to Puerto Rico indicate similar conditions to have prevailed over most of the country. There was naturally exceptions to the rule but the hours long openings to one area of years past were in general few and far between. Openings to the Pacific Northwest seemed more frequent than in recent years. Several years back the writer spent the better part of three summers attempting to work Oregon for number 48, finally working K7RWT. This year Dave was worked on three occasions and other contacts in Oregon, Washington and British Columbia were commonplace. WA7UBI was a very popular Idaho station, contacts being reported by many. K6TYW/7 was also busy passing out Idaho to the many who need it.

W4GDS says he received numerous VP5RS QSL's without an SASE, these will not be answered until the sender provides one. Bob, Joe and Hoppy made over 1000 contacts on 6 meters and 2500 on HF during their brief stay on Caicos, the cost of postage alone on this many cards is staggering, not to mention the writer's cramp involved in addressing that many cards. If you forgot to do your part, do it now if you want confirmation of this rare one.

WA1EXN reports the VE1ASJ DXpedition to Prince Edward Island didn't get off the ground due to rig problems the previous night. Hopefully Andy's second try in late July was more successful. Art also reports K7ZOK is waiting for confirmation of a New Hampshire contact with WA1GCU to complete his second WAS on 50 MHz. He already has one from previous activity in Zero land. This must be a first.

Dick, WB8GZL, told me the other evening about the Ohio 6 meter net. This group meets on 50.160 at 0100 every evening. Monday through Saturday, the net is called from Dayton; Dick is net control from Waverly on Sunday. There are an average of 25 or so check-ins from 4 or 5 states. Calls are made in all directions and additional check-ins are solicited.

Several months ago in this column, assistance was offered to anyone having a problem with equipment, TVI, getting on the air or whatever. I enjoyed hearing from many of you and trust the answers and references supplied were helpful. The offer still stands and will as long as time is available. There are only two criteria: the problem must concern 6 meters and an SASE must be enclosed. It would be helpful if as much information as possible is included. Brand of rig, schematic diagram (or the source of same if it is home brew equipment), details of what happens (or doesn't happen), are often left out requiring further correspondence and unnecessary delay.



In connection with the above, the answer to one question already asked several times is as follows. Frequency instability in early Swan 250's may usually be cured by one or both of the following. Do not operate the rig in close proximity to an open window, air conditioner, or fan. Cover the "frequency range megacycle" capacitor with a cardboard box or a plastic sandwich bag. Either, when taped to the chassis around the edges, will prevent airflow across the capacitor and the associated drift in frequency. Another problem common to this rig is instability in the carrier null setting. The best fix I know of is to replace the carrier null potentiometer with the best grade composition pot you can find. The Ohmite type AB or the Allen-Bradley type J are recommended.

Response to a previous request for source material for this column was quite good but there remain areas from which no response has been received. Active and knowledgeable hams are a very necessary part of a 6 meter column, conditions and activity vary widely from one area to another and only through reports from YOUR area can the condition of our favorite hobby be accurately evaluated. Drop me a card and I'll explain what is needed and the time factor.

The ARRL has announced a new (3rd) edition of the VHF Handbook, it has not however appeared on the shelves of the local ham emporium. A new (19th) edition of the Editors and Engineers Radio Handbook is also due shortly. Both of these volumes are required reading for any serious 6 meter ham.

AMSAT NEWS

Michael Frye WB8LBP
640 Deauville Dr.
Dayton OH 45429

Rescheduling of A-O-C Launch

A shuffling and rescheduling of Delta launch vehicles by NASA has caused a four-month delay in the launch of the OSCAR-6 (A-O-C) satellite. The launch of the ITOS-C meterological satellite has been cancelled, and NASA has decided to launch ITOS D (on which A-O-C was to piggyback) with the ITOS-C launch vehicle. Unfortunately, the ITOS-C booster does not have sufficient payload margin to allow OSCAR-6 to be launched with the ITOS-D. NASA has therefore rescheduled our satellite as a secondary payload on the NIMBUS-E meterological mission presently scheduled for launch in November of this year, pending approval of the NIMBUS project office. A-O-C is now expected to be placed in a 690 statute mile circular polar orbit with a period of 108 minutes and an inclination of 99.9 degrees. A sun synchronous orbit is planned with overhead passes expected around local noon and midnight each day.

Reprinted from AMSAT newsletter

This delay mentioned above will allow time for AMSAT to mold together a lot of projects it is currently involved in. Such things as a workable communications network to broadcast information direct from the launch site to amateurs all over the world. In addition AMSAT still needs volunteers to complete its ground command network. After the launch, amateurs are needed that will perform day after day. With the dependability of a net worker, to copy down the data from the telemetry unit and send it to AMSAT.

Another interesting note is that the FCC has approved the waivers sent to them by AMSAT. That is, in addition to other allowances, novices and technician class licensees can operate through the two-to-ten repeater on board A-O-C. This will allow a lot of newcomers to the field to participate in this exciting project.

Please send questions, comments, etc. as I would like to know how this column is being received.

WB8LBP

The Golden Jubilee Hamfest of the Northern Alberta Radio Club is all set for the 16th and 17th of September 1972. The event will take place in the Silver Slipper Saloon on the Edmonton Exhibition grounds. Pre-registration, at $9.00 per person will be accepted until August 15th. Regular registration, which will begin at the Hamfest site on the evening of Friday, September 15 will be at the rate of $10.00 per person. Children's admission to the Sunday morning breakfast in the park will be $1.00 per child.

All those attending will have a chance at valuable prizes. Also, there'll be technical and social events, bunny hunts, and other technical contests, a banquet and a casino in the saloon.

Bring along the kiddies and the XYL. You can park your trailer right nearby if you wish. There'll be special events and prizes for the ladies.

Listen on 80, 40, 20, 15, and 10, and on 2 meters for VA6NC, the special Hamfest station. We'll have special QSLs for all contacts.

* * *

The Peoria Area Amateur Radio Club, Inc. will hold its 15th annual Hamfest Sunday, September 17, 1972 at Exposition Gardens (same place as last year), located on the northwest edge of Peoria, IL. Lunch will be available. There will be plenty of activities for the entire family, beginning with the campsite opening the preceding evening and the banquet Saturday, Sept. 16 at V Junction, $5.50 per person. Door prizes for men and women, cocktail hour 5:30 to 6:30, dinner 6:40. Two motels within walking distance. Free coffee and donuts from 9:00 to 9:30 AM CDT.

Free swap section, parking, contests, cartoons for kiddies and of course the many eyeball QSO's. Advance registration $1.50, at gate $2.00. For further details and advance registration for banquet or Hamfest tickets write Wendell McWilliams, WN9DVJ, Box 1, Rome, IL 61562.

VK/ZL OCEANIA DX CONTEST 1972

WIA and NZART invite all amateurs to participate in the 1972 VK/ZL/O DX Contest. The usual contest rules apply, while the following is a summary of the important facts, condensed to aid publicity.

1. When – Phone: 24 hours from 1000gmt Saturday 7 October to 1000gmt Sunday 8 October.

2. CW: 24 hours from 1000gmt Saturday 14 October to 1000gmt Sunday 15 October.

3. Scoring: For Oceania Stations other than VK/ZL: 2 points for each qso on a specific band with VK/ZL; 1 point for each qso on a specific band with the rest of the world. For Rest of World other than VK/ZL: 2 points for each qso on a specific band with VK/ZL; 1 point for each qso on a specific band with Oceania stations other than VK/ZL.

4. Final Score: is derived by multiplying total qso points by the sum of VK/ZL call areas worked on all bands. (The same VK/ZL call area worked on different bands counts as a separate mult).

5. Serial Numbers: Will consist of five or six figures made up of the RS(T) report plus three figures which should commence with 001 and increase by one for each successive qso – 002, 003, etc.

6. Logs: (a) Must show in this order: Date, time in GMT; call sign of station contacted; band; serial number sent; serial received. Underline each new VK/ZL call area contacted and make separate log for each band used. (b) Summary sheet to show call sign; name and address (use block letters please); details of equipment used; and for Each Band, qso points for that band and VK/ZL call areas worked on that band. "All Band" score will be total qso points multiplied by sum of VK/ZL call areas on all bands while "Single Band" scores will be that band's qso points multiplied by VK/ZL call areas worked on that band. **Sign a declaration that all rules and regulations have been observed.

7. The usual attractive certificates will be awarded to each country (Call Area in W/K, JA/JH etc.) on the following basis: (a) Top Scorer using "all bands" (b) Separate awards for phone and CW and (c) Other certificates will be awarded (e.g. 2nd/3rd and separate bands awards depending on conditions and activity).

Listeners' Section to count for points, a VK or ZL station ONLY must be heard in a qso and the following details noted in the log – date, time in gmt, call of the ZL or VK station heard, call sign of the station he is working, RS(T) of the VK/ZL station heard, serial number sent by the VK/ZL station heard, band, points. Scoring is on the same basis as for the transmitting section and the summary sheet should be similarly set out.

All logs should be posted to reach: NZART CONTEST MANAGER, Box 489, Wellington, N.Z. or NZART CONTEST MANAGER, 152 Lytton Rd. Gisborne, N.Z. before 25 January 1973.

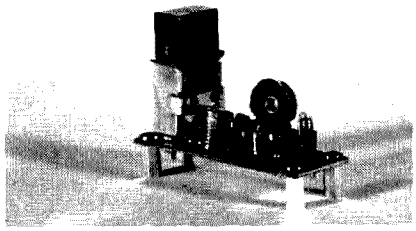
The ILLINOIS REPEATER COUNCIL proudly announces its birth. Your Repeater Organization is needed to help us grow. Tell your President, or Trustee to contact: Ray Thill WA9EXP, P.O. Box 455, Arlington Heights, IL 60006, or call: 312-253-2058. The IRC is currently composed of member repeater and remote base organizations representing over fifteen hundred FM'ers. Membership is open to any such organization operating in the state. The next meeting will be August 17, 1972. Call or write for details.

* * *

KENTUCKY HAMFEST. The Greater Louisville Hamfest will be held August 27, 8 AM to 5 PM at Pine Grove, Otter Creek Park, S.R. 1638 off U.S. 31W near Fort Knox. Registration is $1.00, Fleamarket, $1.00, Door Prizes, Food, Picnic Tables, Auction, Ladies Program. Contact: Guy Partridge, K4KZH, 8276 Walker Rd. Louisville KY 40258.

* * *

An Operating Achievement Award Certificate signed by Governor Daniel J. Evans will be offered by the Puget Sound Council of Amateur Radio Clubs for contacts made during Washington State Amateur Radio Week, September 9th through 17th. For further information write to The Puget Sound Council of Amateur Radio Clubs, 12306 80th Avenue, East Puyallup, Washington, 98371.

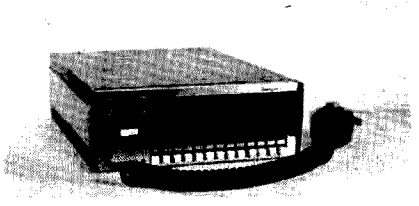


* * *

18TH. ANNUAL VHF CONFERENCE at Western Michigan University, Kalamazoo, Michigan will be held October 21, 1972 (Saturday). Flea market, speaker from AMSAT, etc. For full details write: VHF Conference, PO Box 934, Battle Creek, Michigan 49016.

NEW PRODUCTS

SUB-AUDIBLE TONE ENCODER



The Communications Specialists continuous tone encoder is a wee one, about 2½" long, 7/8" wide and 1¾" high. It uses the resonant reed made by Motorola or Bramco to determine the exact frequency. The oscillator will operate over the range from 67 to 3000 Hz.

The unit pictured has a Motorola 4A reed plugged in, resulting in a continuous 141.3 Hz tone being generated. There are a few repeaters that are turned on by this type of tone instead of the more ordinary carrier operated system. These are listed in the Atlas with a "PL" or "PL4A." If you run up against a PL type of repeater without knowing it, frustration can set in rapidly. You can hear fellows talking with each other over the repeater even though you cannot break through. These are in use by some repeaters who wish to be more exclusive than others such as WA2UZE on Long Island and WA2UWR in New Jersey. PL stands for Private Line, a Motorola patent and trade marked term.

The above encoder costs $14.95 wired and tested from *Communications Specialists, Box 153, Brea CA 92621.* The reed is an extra $17.50. The connections are simple – 12 volts and one audio wire. The unit is small enough to fit inside of just about any FM transceiver made.

SIMPSON MODEL B FM TRANSCEIVER

How about a 12 channel two meter FM transceiver with a full 25 watts output? The Simpson Model B has been getting rave notices in the VHF marine field, but has not been formally introduced to the amateur market yet.

The Model B Simpson uses the same boards as the well known Model A – and beauties they are, too – plus a 25 watt transistor power amplifier. No tube here, this is all solid state power. The receiver output goes into a front speaker with two full watts of audio power so you can turn up the volume control and hear this speaker clearly and without distortion even in a tractor. It's designed to be heard over the roar of a boat engine. The front speaker is a great advantage as the sound from the big oval speaker comes straight out at you, not via the floor of the car or from under the dashboard.

In the low power position the rig puts out one watt – which is handy now and then. The 25 watts will help your signal to go over hills, around buildings, and generally get into the repeater a whole lot more than the lower powered transceivers will.

The instruction manual is a marvel of clarity – complete with blown up layouts of the circuit boards which show the profusion of test points and clue you into the schematic diagram. This manual is put together for a technician, not an appliance operator.

The price for this gem – about $300 – how can they do it? By selling direct and cutting down the normal markup substantially.

Note that they have not skimped in the area that several manufacturers have: trimmers for the receiver. The fact is that most crystals will not hit the receive frequency exactly and if your receiver is at all sharp the chances are very good that you will be listening off to one side of the repeater. This rig has trimming capacitors on both the transmit and receiver crystals – and not those inexpensive compression types either, these are miniature (and expensive) air padders! Each one has a plastic shield so you won't bend it when you stab it with a screw driver and miss the first time or two. This is just typical of the attention that Simpson has lavished on this rig.

The amateur who has any enthusiasm for getting into a rig and modifying it can have a ball with the Model B. With a little prodding it might be possible to buy an extra oscillator board from Simpson which provides a second set of twelve push buttons. This can be mounted immediately under the present board, giving you a 24 channel transceiver. At least one such modification has been made, so this is not pure conjecture.

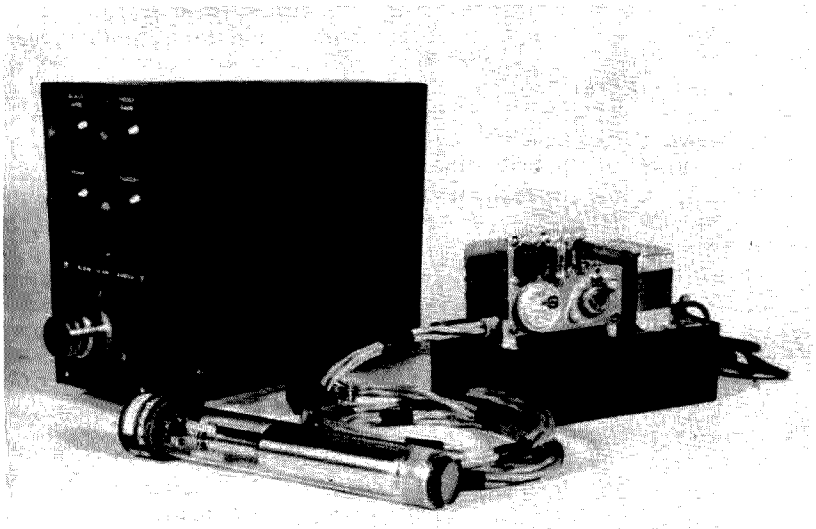
The enterprising amateur interested in whomping up a repeater could do a lot worse than start with the Model B. Indeed, one commercial firm has done exactly that, though they apparently have run into some difficulties doing this in production quantities, judging from the complaints. Nevertheless, the B boards are suitable for such a modification, the transmitter being on one side of a completely shielded box and the receiver on the other. Even the little 25 watt amplifier is in its own box, connected by coax cable, complete with a plug in the cable.

It is unlikely that any article submitted to *73* on modifying the Model B (or, indeed, the Model A, which is very similar to the B, but runs a mere ten watts) for repeater use would be given short shrift. *Simpson Electronics, Inc., 2295 NW 14th St., Miami FL 33125.*

GENAVE 2m FM TRANSCEIVER

The General Aviation GRX-2 FM transceiver will have some of the other manufacturers getting a little on edge. Here is a ten channel push button rig that is solid state and has a full 30 watts output!

The size is small – only 2½ x 6½ x 10" deep. It should fit just about anywhere in the car – and that 30 watts should get the user into the repeater, even if the repeater has a bigger mouth than ears – which many have.



The layout is clean. The bottom is wave soldered so there is little chance that parts are going to be cold soldered or break loose. The trimming capacitors are right out there in the open where you can get at them easily to tweak onto channel. The high-low-off power switch is a nice deal in that you don't have to lose your volume setting every time you turn off the rig. It gets to be a bother to have to turn off the squelch and adjust the volume every time you turn on a rig. Hooray for a separate power switch. The low power position is handy for saving your car battery or for use if you decide to make a shoulder portable out of this unit with a few rechargeable nicads.

The mike plugs into the side of the rig, which many seem to prefer now to front jacks. It does keep it out of the way. This rig is so clean inside that even a rank amateur (pardon the term) would have no problem in moving the mike jack to the back of the rig, if he wanted. The chap who likes to fool around and add things will have a ball with this transceiver – for despite its small size, there is all sorts of room inside to play

The loudspeaker is immense for a wee transceiver, four inches in diameter, and the audio power is there to push it – 1.5 watts! They don't have a jack to feed this to the car radio speaker, but it shouldn't take you ten minutes to put one in. There is plenty of room on the back of the rig to drill

(Continued on page 106)

Construction of a PLUMBICON SSTV Camera

Introduction

The use of fast scan vidicons in slow scan TV cameras was described by Taggart in *QST* for December, 1968 and by Hutton in *73* Magazine for February, 1969. Several amateurs have experimented with fast scan vidicons in SSTV camera circuits but the overall results have not been as good as expected. The problem is one of dark current, i.e. the inability of the vidicon's target to discharge properly when scanned at slow rates causing a picture to be gray and white, not black and white. The resulting pictures do not have the full range of gray scales as those generated with a flying spot scanner or a 7290 vidicon slow scan TV camera. The only sucessful use of a fast scan vidicon in the slow scan mode has been in the sampler type of operation as described by Stone in *Ham Radio* for July, 1971, or by Miller in *CQ* for August, 1969.

A new camera tube suitable for use in amateur SSTV cameras has appeared on the scene and is called a Plumbicon[1]. This tube was developed in Europe by The Phillips Company and is used in many color TV cameras in this country. The first use of this tube in a SSTV camera known to me is by Art Backman SMØBUO and was briefly described in *ATA International* for May 1969. Bob Taylor W4YHC was able to acquire several of these tubes and I, along with several other SSTV experimenters, have been building cameras using the Plumbicon. The camera described in this article is the results of experiments carried on by Bill Briles W7ABW and me. The pictures produced by this camera are of the same quality as that produced by a 7290 vidicon equipped SSTV camera. The construction is very straightforward and the adjustment is no more critical than for any vidicon equipped camera.

1. Plumbicon is a registered trademark of the North American Phillips Company.

How It Works

In the camera block diagram, the vertical oscillator and amplifier is used to generate a sweep voltage at 1/8 Hz to deflect the

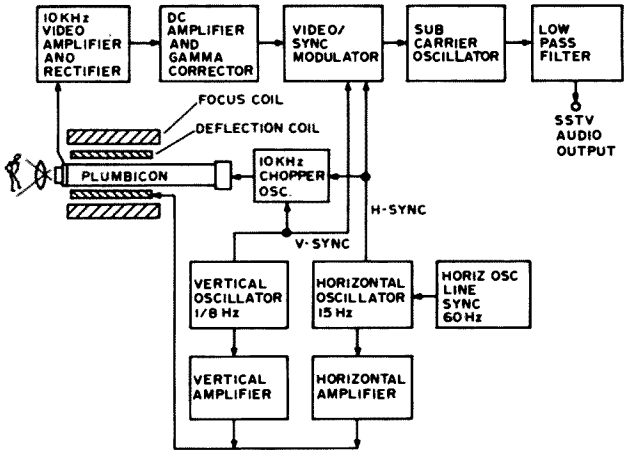

Fig. 1. Block diagram.

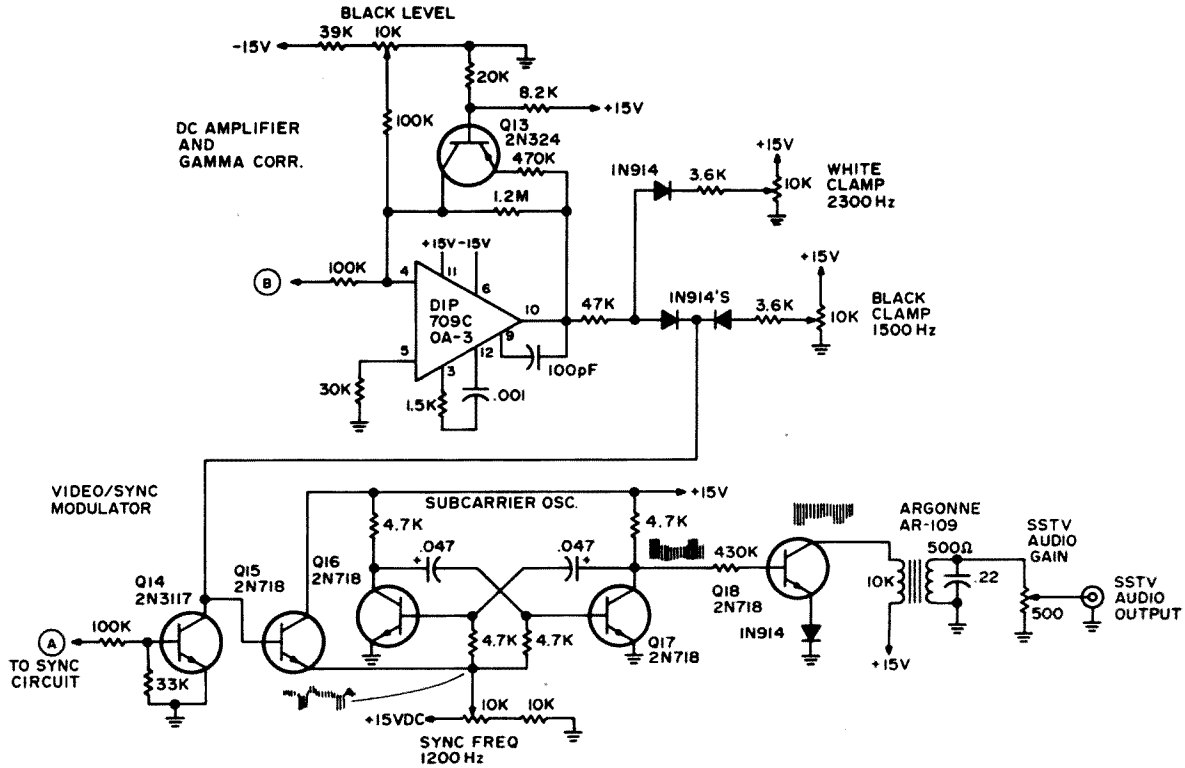
electron beam in the Plumbicon vertically. The horizontal oscillator which is synchronized to the 60 Hz power line is amplified in the horizontal amplifier and is used to deflect the electron beam in the horizontal direction at 15 Hz. This deflection will generate a scanning raster on the back side of the camera tube target of 200 lines in 8 seconds. The electron beam is chopped at a 10 kHz rate by the sync keyed 10 kHz oscillator.

The target voltage appearing at the output of the Plumbicon is an ac signal which is amplified in a two stage amplifier. The output of the "video" amplifier is rectified and the signal is then amplified in a dc amplifier whose response is controlled by a Gamma corrector. This is done to correct the response of the camera tube to that more like the human eye. (Similar to the standard vidicon response). The amplified dc signal is fed to the video/sync modulator where the polarity of the video signal will cause the subcarrier oscillator to swing anywhere between black (1500 Hz) and white (2300 Hz) depending upon the picture content. Vertical and horizontal sync pulses are sent from the sweep oscillators to the video/sync modulator which causes the subcarrier oscillator to swing down to 1200 Hz during the presence of either a vertical or horizontal sync pulse. The square wave output of the subcarrier oscillator (a free running multivibrator) is filtered in the output and the SSTV audio signal is now ready for transmitting over the air on a SSB transmitter, monitoring, or recording on a tape recorder.

Construction

The camera shown in the photographs is the second version constructed. The first



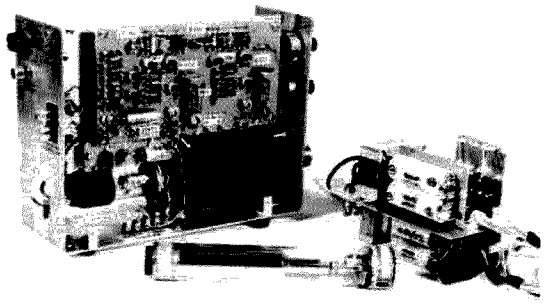


Fig. 2. Schematic (Part 1).

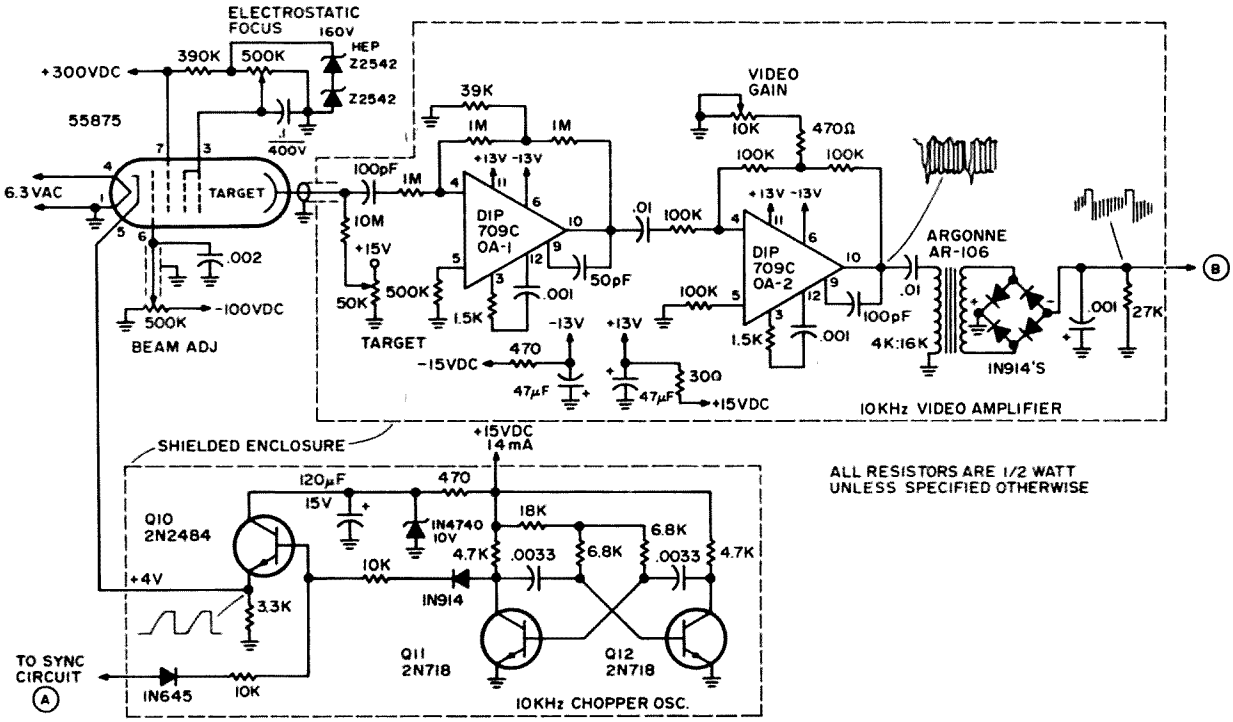
Innards of Plumbicon camera.

model had an integral power supply, but it gave nothing but trouble from its strong magnetic field. Extensive shielding of the transformer compartment with conetic material failed to reduce the interference to an acceptable level. The Plumbicon is very susceptible to stray magnetic fields which show up in the monitor as vertical stripes. The power supply was moved to a separate chassis and the camera rebuilt. It then produced excellent hum-free pictures. The camera electronics assembly is 3½" wide by 7½" high by 9¾" deep. The power supply is built on a plastic instrument case 3¾" wide by 2" high by 6¼' deep. Power from the unit to the camera head is provided by a multi-wide cable and a Jones plug at the camera head rear panel.

The electronics for the camera was assembled on perfboards using push pins. The 10 kHz chopper oscillator and video amplifier should be assembled in shielded boxes as shown in the photographs. The boxes were made from galvanized tin and are 3¾" wide by 4¼" deep by 1¼" high for the video amplifier, and 1¼" wide by 4¼" deep by 1¼" high for the 10 kHz chopper oscillator box. The 10 kHz chopper oscillator, the video amplifier, the dc amplifier and gamma corrector, the subcarrier oscillator, the video and sync modulator, and the SSTV audio output stage are mounted on one side of the camera. On the other side of the unit, the circuit board containing the 60 Hz line sync, vertical and horizontal sweep oscillators and amplifiers, the magnetic and electrostatic focus circuit are mounted.

Sockets for Plumbicons are usually difficult to locate, so one was easily made from an old octal socket, by drilling out the center to pass the glass seal on the base of the camera tube and also, drilling out one of the socket pins for the alignment pin.



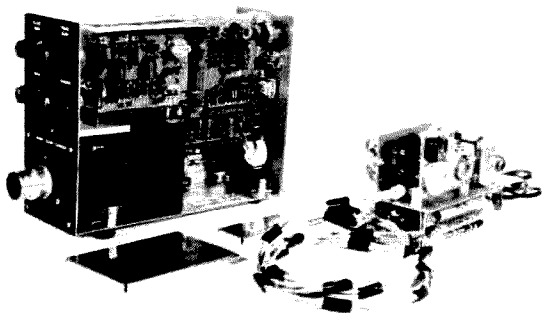


Fig. 3. Schematic (Part 2).

Plumbicon camera with video amplifier and 10 kHz chopper oscillator exposed.

The Plumbicon deflection yoke and focus coil were handmade, as there are no kits for this type of assembly. Information on the techniques of making camera tube deflection components may be found in *ATV Anthology* available from *73* Magazine. The focus coil form was made from a cardboard mailing tube 4½" long with an inside diameter of 2". The focus coil plywood end bells are 3-1/8" by 3-1/8" by 1/4" thick, and are glued over the ends of the cardboard tube making the coil winding area 3¾" long. This form was wound with approximately 5000 turns of number 32 wire. The dc resistance was around 400 plus 50 or minus 100 ohms.

Due to the lower vertical and horizontal sweep frequencies used in SSTV, the deflection coils will contain more turns of wire than those used in fast scan TV. The deflection coil window form was 1½" by 3/4" by .050" thick. Each vertical coil has approximately 620 turns of #36 wire. Each horizontal coil has approximately 800 turns of #36 wire. The series dc resistance of the two vertical deflection coils is 320 plus or minus 20 ohms and the resistance of the two horizontal coils in series is 220 plus or minus 20 ohms. The important thing is that each pair of coils be matched in individual resistance (same number of turns) or you will have unequal deflection in that particular plane. The Plumbicon is a bit larger in both diameter and length than the standard vidicon and will require a deflection coil form with an inside diameter of approximately 1¼". Such a form may be found inside a box of plastic sandwich bags, and should be cut to a length of around 5 inches. Install the Faraday shield, and deflection coils on the form as per the procedures in the *ATV*

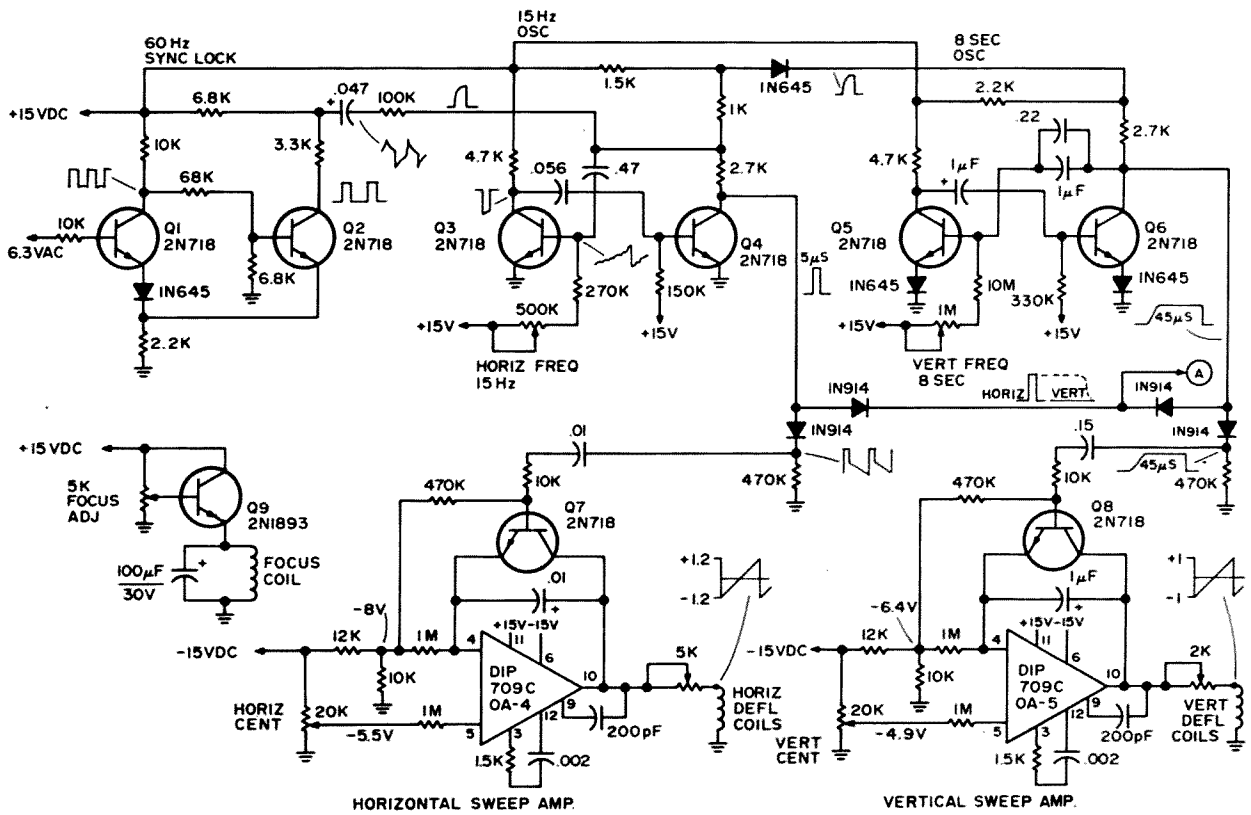

Fig. 4. Schematic (Part 3).

Anthology. Watch out when you phase those coils as I connected my vertical coils out of phase and had no vertical deflection when the camera was first tested. (I had built over a half dozen of these vidicon deflection assemblies and became over- confident!)

The lens of this camera was salvaged from a surplus gun camera. It is of 25mm FL and required a spacer of about 3/8" between the front of the focus coil assembly and the back of the front panel. The exact spacer required for each camera will depend upon the lens used and its focal length.

Camera Adjustment

It is a good idea to check out the various circuits of the camera before plugging in the camera tube. Using a dc oscilloscope, check for proper wave forms and voltages at the junction of the two resistors in the collector of Q-2. This is to confirm that the 60 Hz lock-in pulses are being generated. Observe the output of Q-4 and adjust the Horizontal Frequency Control to 15 Hz. While monitoring the output of Q-6, adjust the Vertical Frequency Control to one pulse every 8 seconds. I use a stop watch to check the timing of the vertical oscillator. Now move over to the output of the horizontal sweep amplifier and set the Horizontal Size and Centering Controls to obtain the deflection voltage and wave shape as shown on the diagram. Repeat the same procedure for the output of the vertical amplifier.

Check the output of the 10 kHz chopper oscillator by monitoring the output at the emitter of Q-10, or pin 5 of the camera tube socket. To adjust the subcarrier for proper operation, connect a jumper between the collector and emitter of the sync modulator Q-14 and adjust the Sync Frequency Control for 1200 Hz as monitored at the SSTV audio output connector. Remove the jumper and adjust the White Clamp Control so that the wiper is at the 15 volt end. Remove the dc amplifier OA-3 and adjust the Black Clamp Control for 1500 Hz as monitored at the SSTV audio output connector. Reinstall OA-3 and adjust the Black Level Control to about 2/3 of its control rotation toward the minus 15 volt end. Now adjust the White Clamp Control for 2300 Hz as monitored at the SSTV audio output connector. Adjust

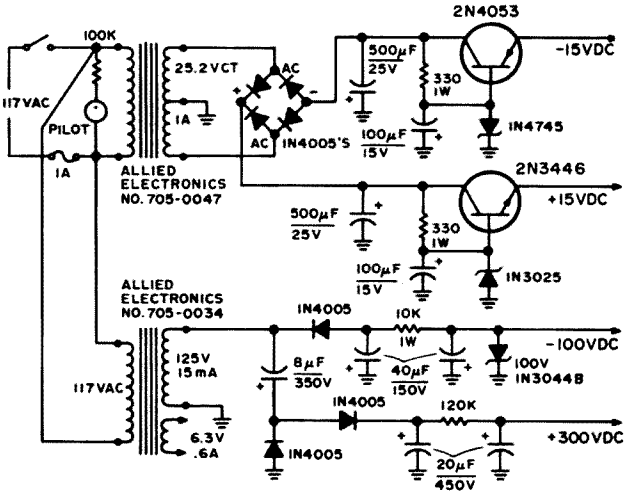

Fig. 5. Power supply unit.

the Black Level Control back to a point where the SSTV audio output is 1500 Hz.

Turn off the power now, and install the socket on the camera tube. The following table is a list of the control settings and voltages at critical points as found in the K7YZZ SSTV camera. They will provide the builder with a good starting point when beginning final tests and adjustments.

Beam	-41.5V
Target	+15V
Electrostatic Focus	+62V
Magnetic Focus	+5.3V
Black Level	-.40V
White Clamp	+4.8V
Black Clamp	+3.8V
Sync Freq	+3.0V

It should be noted that there is interaction between the optical focus, electrostatic focus, and magnetic focus in the process of getting the sharpest and best quality picture from the camera. For portrait work I use a black cloth background and a couple of Sylvania Soft White 40 watt bulbs in reflectors to illuminate the subject. The Soft White light seems to have the best output for the Plumbicon tube. I spent around two weeks experimenting with the controls and lighting, learning how each one affected the camera operation. The thing with slow scan cameras is to not get in a hurry but take your time and the end results will be very gratifying.

I wish to thank Bob Taylor W4YHC and Bill Briles W7ABW for their help during the construction and testing of this camera.

WWVB 60 kHz FREQUENCY COMPARATOR RECEIVER

This system uses a heterodyning and intergration process to display the error between WWVB at 60 kHz received frequency and a local frequency standard on a linear phase versus time plot. Before describing the theory of the system there were certain design criteria requirements.

1. Low cost ($50) exclusive of recording system.
2. Straightforward construction and no critical circuit adjustments.
3. Resolution to 1 part in 10^{10}.
4. All solid state using readily available RTL IC devices.

Introduction

Many frequency control system applications dictate the use of secondary frequency standards sharacterized by fractional frequency stability better than a few parts in 10^8. Instrumentation packages which employ internal secondary frequency standards include digital counters, frequency synthesizers and communication equipment. Low cost frequency standards and most instrument packages employ a quartz-crystal controlled oscillator having stabilities better than a few parts in 10^8.

All secondary frequency standards exhibit frequency drift characteristics which, over a period of time, result in cumulative frequency errors. The term "aging rate" is used to describe the time rate of change of the oscillator frequency. For quartz-crystal standards the aging rate itself is a variable which tends to decrease in magnitude with time (when the oscillator is operated continuously without interuption of power). Practical means for calibrating secondary frequency control devices against reliable sources of known frequency (primary standards) are required in order to maintain reasonable limits of output frequency uncertainty.

HF and LF Propagation

The hf transmissions from the National Bureau of Standards (NBS) stations WWV and WWVH are radiated at precisely known frequencies: however, due to the relative instability of hf propagation, variations of a millisecond or more in path delay are experienced. Changes in path delay in turn cause apparent received carrier frequency fluctuations. These effects cause measurements of the hf carrier frequency, or of the time-tick modulation period, to become very time consuming. Resolution of a part in 10^9 requires about two weeks.

The lf transmissions from NBS station WWVB at 60 kHz are far more stable because the signal is propagated as if it were in a waveguide (i.e. the surface of the earth and the lower regions of the ionosphere forming the wave guide). Since the ionosphere acts as a boundary rather than as a direct reflector, its variations have a much reduced influence. Variations in propagation conditions due to the ionosphere do, however, exist and techniques are available for

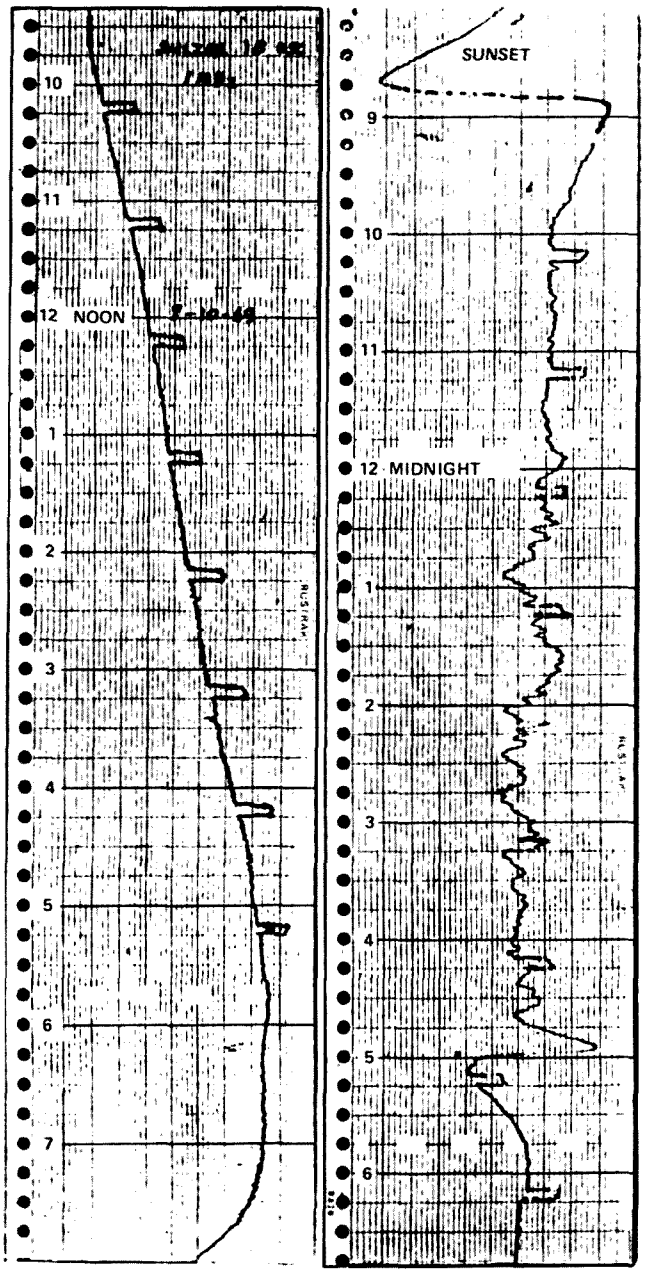

Fig. 1. Chart recordings.

working around them. Factors affecting path phase velocity include ionospheric conditions (diurnal shift-phase shifts occurring at sunrise and sunset), ground conductivity, and surface roughness. Since the phase velocity of long range lf signals depends to an extent upon the effective height of the ionsphere, sudden atmospheric disturbances such as those occurring during solar flare events will cuase sudden phase anomalies. Diurnal phase shifts and other anomalies are not a serious problem provided the user is aware of them. Resolution of part in 10^{10} requires less than a day using lf frequency transfer techniques.

PRICES SLASHED!

7-SEGMENT READOUT Plug-in, 5V-60 ma. per segment. $3.85, 10/2.85, 100/2.49. Mating socket, .40.

Frequency

Frequency tolerances are normally expressed in some part in 10ths. The following example shows the relationship between parts in 10ths and cycles per second.

Total μsec per day = $\frac{1{,}000{,}000\ \mu\text{sec}}{\text{SEC}}$

$\frac{60\ \text{sec}}{\text{MIN}} \quad \frac{60\ \text{min}}{\text{HR}} \quad \frac{24\ \text{hrs}}{\text{DAY}}$

$=86{,}400{,}000{,}000$ μsec per day
OR $86{,}000 \times 10^{6}$ μsec per day
OR $8{,}640 \times 10^{7}$ μsec per day
R 864×10^{8} μsec per day
OR 86.4×10^{9} μsec per day
OR 8.64×10^{10} μsec per day

In frequency comparison the following term is used.

8.64 μsec = 1 PART IN 10^{10} per day
17.28 μsec = 2 PARTS IN 10^{10} per day
86.4 μsec = 1 PART in 10^{10} per day

As an example consider a 1 MHz oscillator which has drifted 6 parts in 10^{10} during a 24 hour period. This represents a total of 51.84 μsec. Average frequency of the oscillator during the measurement period is:

Fav = Fnom 1 + △F/F Where Fav = average frequency

Fnom = nominal oscillator frequency

△F/F = average frequency error parts in 10ths

Fav = 10^6 (1 + $6/10^{10}$)
= 1,000,000.006 Hz
Indeed a small error.

Chart Recorder

The If Phase Comparator plots the phase difference of a local frequency standard vs. that of the received carrier by means of the Rustrak strip chart recorder. Full scale chart width is 16 2/3 μsec phase difference. If radio propagation phenomena were perfectly stable, (no noise or other error causing factors) and the local standard is in exact agreement with WWVB at 60 kHz, the chart trace resembles a continuous straight line. If the standards are not operating on exactly the same frequency scale, then the phase of one relative to the other will change with time, thus the chart trace will be a saw-tooth wave shape if the drift is more than 16 2/3 usec.

Referring to Fig. 1 a typical chart recording, the steep phase shifts at 5 AM and 8 PM are associated with differences in daytime and nighttime propagation characteristics. Also, greater phase noise is observed at night due to spheric activity. These factors make it advisable to perform calibration on the basis of daytime data taken either during one day, or taken at the same time on several consecutive days. In the following example, we are using data taken at 11 AM to 5 PM, for six consecutive hours. At 11 AM the chart read 5 μsec and at 5 PM 13.5 μsec. Total drift of the standard is 13.5 − 5 = 8.5 μsec. To use this data enter the charts of Fig. 2 vertically from the bottom (microseconds) to where the line intersects with the slanting 6 hours line. Then project horizontally to the left from the intersection and read fractional frequency error. In this

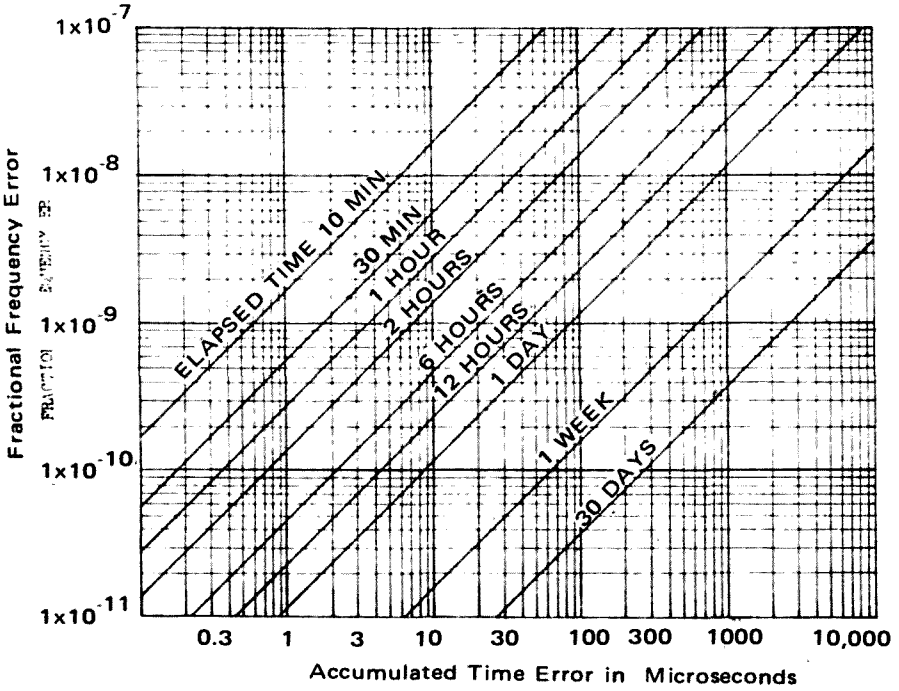

Fig. 2. Accumulated time error vs. fractional frequency error.

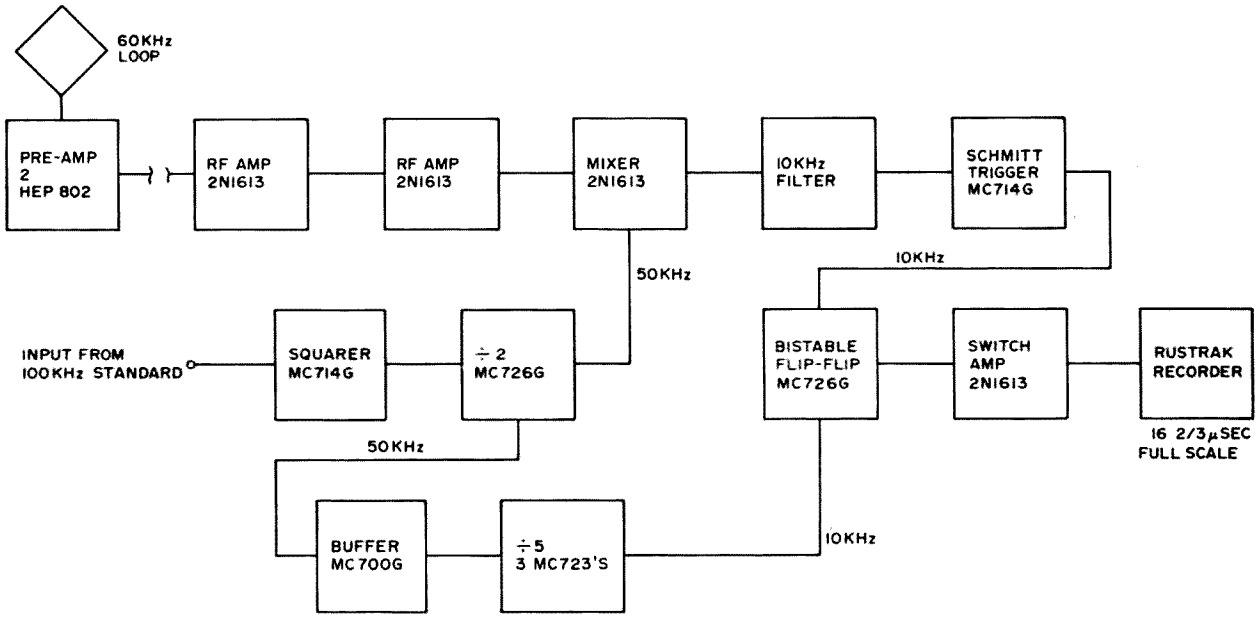

Fig. 3. Block diagram.

case the oscillator drifted 4 parts in 10^{10}

Gaps in the trace are caused by once-an-hour 45 degree phase shifts introduced into WWVB carrier for identification purposes. These gaps begin ten minutes after the hour and end fifteen minutes after the hour. If daylight fading should occur, it is a certain indication that ionosphere disturbances are taking place and are likely to be accompanied by apparent received phase instabilities.

WWVB Signal

Code information is also transmitted along with the continuous carrier. Time code information is presented by means of a level-shift carrier code. The time signals are indicated by 60 drops in the power level per minute, one marking each second and the amount of each drop is 10 dB. Also WWVB is off the air every other Tuesday during the daytime for maintenance.

Since this frequency comparator would operate best from a steady 60 kHz carrier, the 10 dB drop in carrier level does, unfortunately, affect the quality of the recorder trace when approaching either side of the chart.

Theory of Operation

Refer to the block diagram and the schematics for the following description (Fig. 3, 5 and 6).

The loop antenna is a balance unshielded type, wound with plastic covered wire on a wooded frame. Two square loops three and six feet on a side with 30 and 24 turns respectively were constructed and tried with satisfactory performances. The larger loop did furnish a greater signal level to the receiver.

The pre-amp is followed by two rf stages and a linear mixer. An rf gain control R2 is used to control the gain of the two rf stages. The background noise level at If is quite high due to atmospheric noise, lightning strokes and man-made noise. For this reason the system should include a noise suppressor and a very narrow bandwidth filter in order to maximize the signal-to-noise ratio. A pair of silicon diodes, connected back to back to the base of the linear mixer makes an effective noise suppressor and clipping level is controlled by the rf gain control.

A 10 kHz filter follows the mixer. The one shown using the cup cores has a bandwidth of 100 Hz. Several filter configurations were tried including a Q multiplier. Cores salvaged from 88 mhy coils used for RTTY gave a 200 Hz bandwidth. A more optimum bandwidth would be approximately one Hz.

The pre-amp, two rf stages and mixer are the only linear stages used in the receiver. The rest of the stages are either saturated or turned off. This is one panel control and two

trimmer controls located on the chassis.

Local oscillator injection to the mixer is derived from the 100 kHz frequency standard. A dual RTL IC gate converts the 100 kHz waveform to a fast-fall time square wave to act as a clock pulse for the divide-by-two RTL flip-flop. CR1 is to protect the IC from negative-going inputs. One of the two 50 kHz outputs from this flip-flop drives a 50 kHz tuned circuit to change the square wave to a sine wave for the mixer. The other output is fed into a divide by five circuit which generates a 10 kHz output.

The output from the 10 kHz filter drives a dual gate IC that functions like a low-hysterics Schmitt trigger whose threshold level is adjusted by R3. The Schmitt trigger drives one input of a MC726G flip-flop that is used as a Bistable flip-flop. The 10 kHz output from the divide-by-5 circuitry drives the other input to the Bistable flip-flop.

A Bistable flip-flop has two stable states and is forced from one state to the other by turn-off pulses received from WWVB or from the local frequency standard at a 10 kHz rate. When the two inputs are 180 degrees out of phase the integrated output current would be 50 percent duty cycle. As the phase changes between the two inputs, the average current would change and this is the purpose of the 2N1613 transistor and associated components to integrate the Bistable flip-flop output. A O1mA full scale, 1 inch per hour Rustrak recorder is used to display the integrated current.

Construction Hints

Only basic details and approximate dimensions will be covered since the diagrams and pictures are self-explanatory. The pre-amp is built on a 2 by 4-¾" one sided copper-clad printed circuit board and housed in a 5 by 2-¼" Bud CU-2104-A minibox. The receiver used a 4-½ by 9-½" printed circuit board. Scrub the foil side of the board with fine steel wool, soap and water. Rinse in clear water and dry. After the board is completely dry, spray the foil side with clear Krylon and the Krylon does not interfere with soldering. Nearly all components are mounted on the copper foil side of the board. Transistor sockets were used for the 2N1613 transistors but the leads on the IC's were bent and soldered directly. USECO type 1425 terminals were used to mount components onto and for tie points. Coils are mounted, using nylon screws and fiber washers. Approximate parts layouts is shown in Fig. 4.

Acquiring the required cores for the coils may be difficult because they are not across-the-counter or mail order items. The manufacturer usually has a $25 minimum order charge. Therefore, most builders will

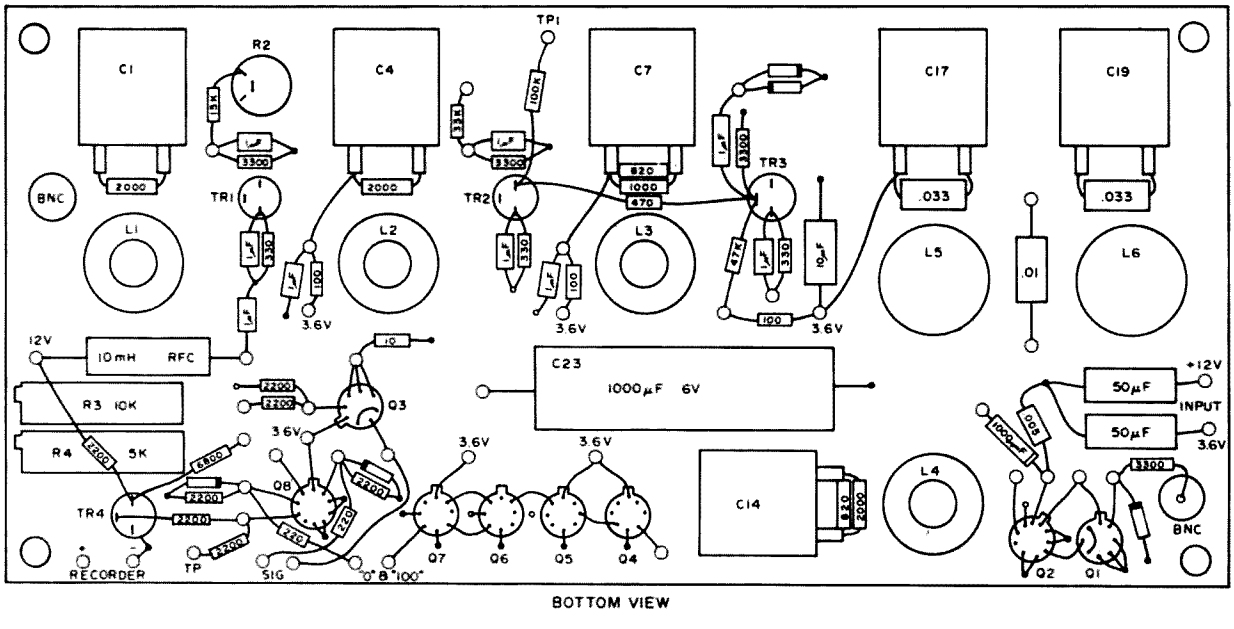

Fig. 4. Components lay-out.

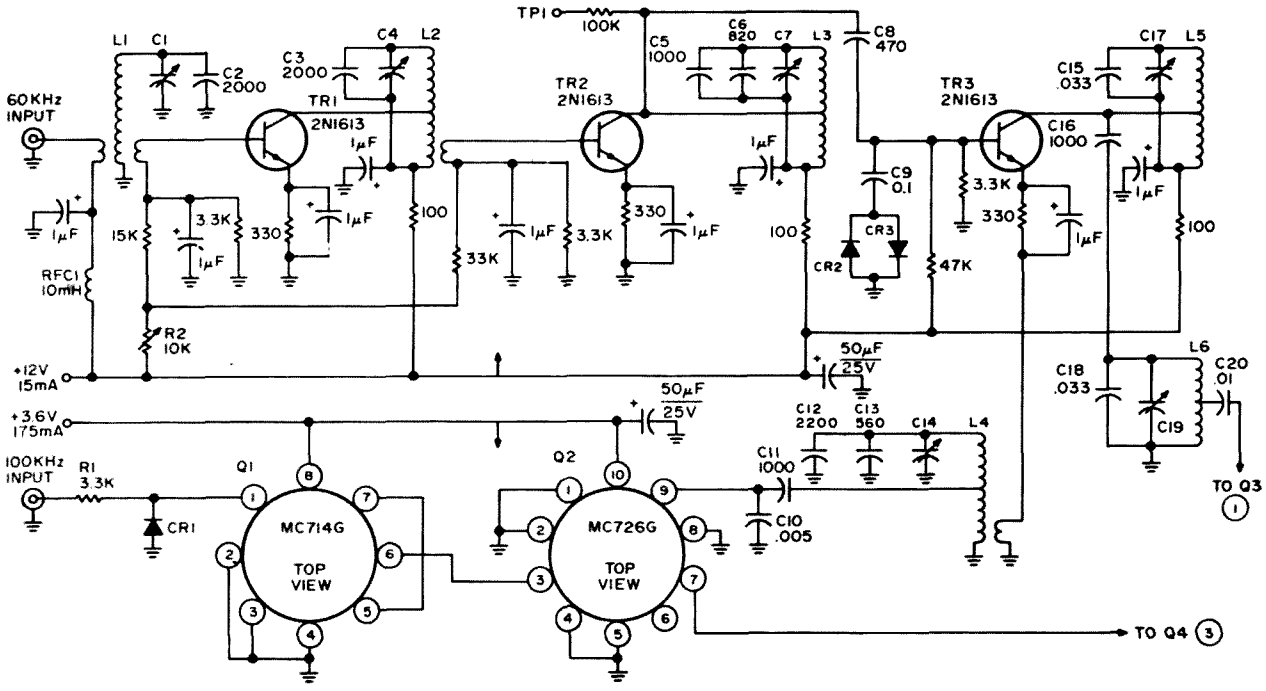

Fig. 5a.

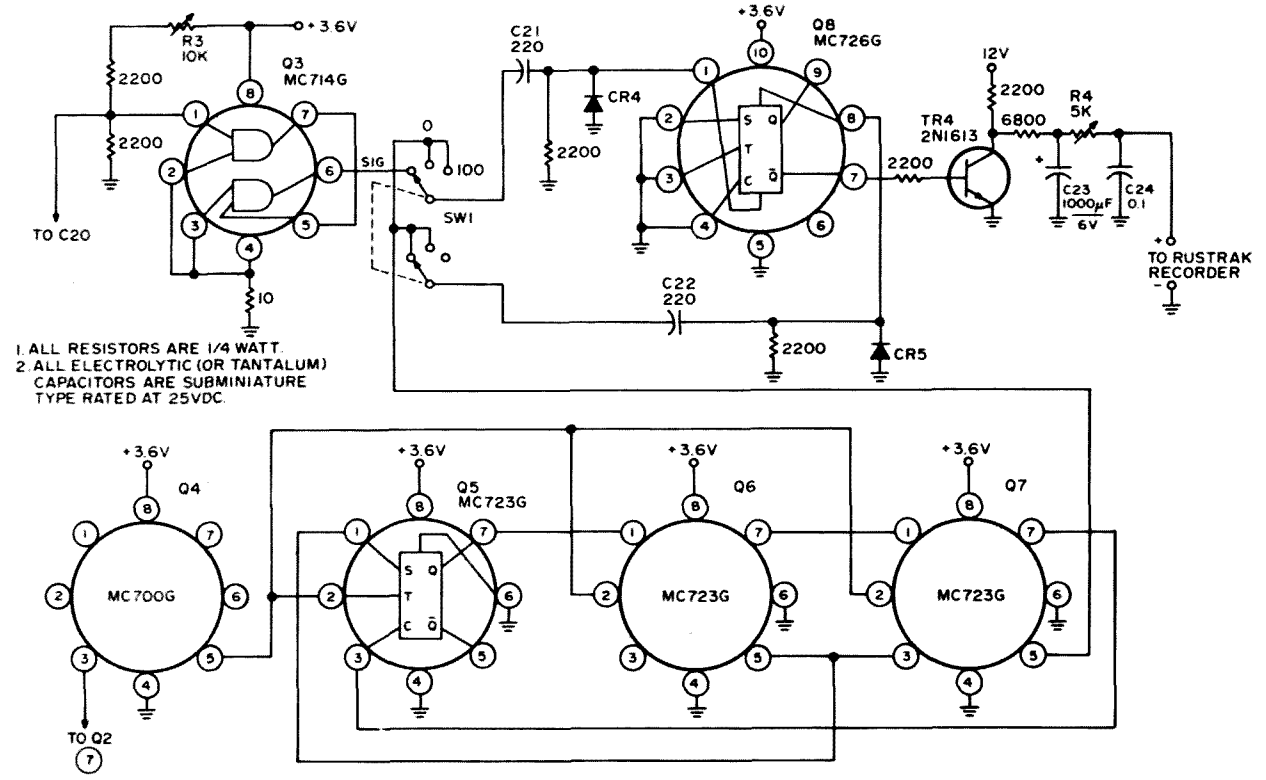

Fig. 5b.

Schematic.

have to do a little scrounging among friends or surplus stores to find suitable cores. The three 60 kHz coils on the receiver board have a Q of 70 and the pre-amp output coil has a Q of 200.

Other RTL IC's may be substituted for the ones specified, such as the Fairchild 914 or Motorola MC724P for the MC714G gates and Fairchild 923 or Motorola MC723P for the MC723G flip-flop.

Adjustment

A signal generator capable of tuning to 60 kHz and an oscilloscope is required. Connect the scope to TP1 and couple the generator to the loop antenna by wrapping a turn or two of test lead around one side of the loop. Peak the loop and the 4 60 kHz tuned circuits to 60 kHz. Move the scope to the mixer emitter and peak the 50 kHz tuned circuit. The 50 kHz signal should be adjusted for approximately 1VPP at the mixer emitter (this is assuming that a 100 kHz frequency standard is connected and the flip-flop is putting out a 50 kHz square wave). The input level of Q1 gate should not exceed 4VPP and may be adjusted by R1 to suit the 100 kHz frequency standard used by the builder.

The 10 Hz circuits can be peaked up by monitoring the Schmitt trigger input with a scope when a 60 kHz signal is fed into the receiver input. After this is accomplished connect the scope to the Schmitt trigger output and adjust R3 for a symmetrical wave form (be sure to keep the generator 60 kHz output level low). Check the output of the divide by circuit for a 10 kHz output. Switch Sw is used for calibrating the Rustrak recorder when the switch is placed in positions 0 and 100. The recorders full scale indication may be adjusted by R4 when the switch is placed in the 100 position. There is no adjustment for zero scale indication.

Disconnect the generator and test lead from the loop antenna. Connect the scope to the mixer base and adjust the rf gain control R2 until clipping of the received 60 kHz signal occurs.

Experience has indicated that best results are obtained when a minimum number of manual corrections are made to the frequency standard to bring it within tolerance. It is desirable to over-compensate, rather than set the standard exactly on frequency. This results in the maximum time period between adjustment in order to maintain the standard within specific tolerances.

Local Frequency Standard

The frequency comparator requires 100 kHz from a local frequency standard with a minimum output of 4 VPP. Crystal calibrators similar to those used in communication receivers are not stable enough for use in this system (the same is true for most crystals mounted in snap action type ovens). A good frequency standard employ a crystal mounted in a proportional control type oven. Most crystals used in frequency standards are 1, 2.5 and 5 MHz with appropriate signal conditioners.

Performance

The performance of the frequency comparator described in this paper meets all of the design criteria requirements. The system phase shift caused by a 20 dB drop in input signal level is approximately 0.33 μsec. The rf gain control will introduce approximately 1.6 μsec phase shift over its full range but this is a fixed shift. With a stable frequency standard the system will phase track a part in the 10. There are limitations to this type of frequency comparator (compared to a complex phase-locking type), but never the less, this system will out perform any hf systems presently in use.

Two common questions have been asked whenever I have demonstrated the 60 kHz frequency comparator receiver and these are:

1. Would there be an error in the comparator measurements as the 100 kHz standard is being divided down to 50 and 10 kHz.

2. Where should the loop antenna be located?

Let's assume that a 100 kHz standard has drifted 10 Hz. A one Hz at 100 kHz is 10 usec long in time and 10 Hz at 100 kHz would be 100 usec. Dividing 100 kHz down to 50 kHz would also divide the drift by two but one Hz at 50 kHz is 20 μsec long and 5 Hz at 50 kHz would be 100 μsec. Thus by dividing a frequency it never changes the error but only the number of cycles.

Referring to the block diagram (Fig. 3), let us assume that the 100 kHz standard did drift 10 Hz high over a period of time. The output from the divide by two circuit will be 50 kHz plus 5 Hz. The 50 kHz plus 5 Hz does however mix with the received 60 kHz signal to produce a 9.995 kHz and this signal drives one input of the bistable flip-flop.

The 50 kHz plus 5 Hz is further divided by five to 10 Hz plus 1 Hz and this signal drives the other input of the bistable flip-flop. The bistable flip-flop counts a difference of 6 Hz between the two input signals. Since everything is in reference to the 60 kHz signal (one Hz at 60 kHz is 16-2/3 μsec) the 6 Hz in μsec would be 6 x 16-2/3 μsec = 100 μsec and this indicates that the 100 kHz standard did drift 100 usec.

As with any antenna the loop should be located clear of all structures, etc. To avoid regeneration, the loop should be at least 30 feet from the comparator receiver. The loop should be pointed edge wise toward Ft. Collins, Colo.

With the 3 foot loop located in the basement the comparator did phase track but the 60 kHz signal level was down. I compromised by installing the loop in the attic and this also solved the weather problem.

This project was for Area 5 MTS of the Air Force MARS program for updating methods of calibrating frequency standards. The writer would like to express his appreciation to Dick Bingham, W7WKR for his assistance in the write up, Bob Ellis, W7FNA/AF7FNA and Fred Reid Jr., W7EJD/AF7EJD for their assistance in the project.

CIGAR TUBE GE Audio-RF Signal Generator

Miniature audio-rf signal generator (Fig. 1) for injecting signals into audio amplifiers or receivers can be constructed with a dozen components and contained in an aluminum cigar tube slightly larger than a pen. The circuit will operate with almost any pair of NPN or PNP transistors, whether silicon and/or germanium, by merely changing the battery polarity for the type transistors used. Surplus computer circuit boards or junked transistor radios can provide almost all the components necessary to construct this simple generator.

CIRCUIT

Circuit

The generator, Fig. 2, is basically an astable multivibrator which oscillates at approximately 1000 Hz. The sharp edges of the audio square wave signal are rich in harmonics up to approximately 200 MHz. and a single 1.5 volt penlight cell supplies the necessary power. Battery polarity for the various types of small signal PNP or NPN transistors is as listed in the table below:

Transistor Pair Type	Battery Polarity
A. 2 NPN silicon	As shown on diagram
B. 2 PNP silicon	Reversed
C. 2 NPN germanium	As shown on diagram
D. 2 PNP germanium	Reversed
E.1 NPN silicon and 1 NPN germanium	As shown on diagram
F.1 PNP silicon and 1 PNP germanium	Reversed

Fig. 1. Cigar tube audio-rf generator.

Construction

An aluminum cigar tube slightly larger in diameter than a penlight cell is used to house the generator. The generator as shown in Fig. 3 was fabricated on a small piece of Vector-Board and wrapped with electrical insulation tape. If more desirable

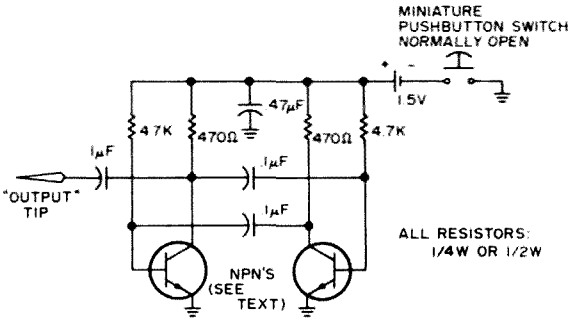

Fig. 2. Note All resistors—¼ or ½ watt.

Fig. 3 Component layout.

the generator may also be constructed on a small printed circuit board or soldered together in a string arrangement and wrapped with insulating tape. A feed-thru insulator with a small pointed tip is attached to one end of the tube to inject the output signal into circuits under test. A small male pin from a scrapped connector could be soldered onto the end of the feed-thru insulator to provide a longer extending output tip. Layout of the components inside the aluminum tube is not critical. A miniature push-button switch is located in the other end to apply power to the multivibrator.

Operation

The signal generator is operated by simply placing the pointed output tip of the generator on the electronics circuit to be tested and depressing the push-button switch on the other end. A wire lead may be connected between the case of the aluminum cigar tube and ground of the circuit to be tested. Grounding may also be accomplished by holding the signal generator with one hand and touching ground of the circuit being tested with the other hand. Signal injection into rf circuits may not necessitate the use of a grounding circuit from the generator to the rf circuit under test.

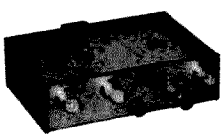
SELECTED
CONVERTERS AND RECEIVERS

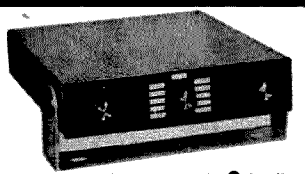
40 dB GAIN 2.5–3.0 N.F. @ 150 MHz



2 RF stages with transient protected dual-gate MOSFETS give this converter the high gain and low noise you need for receiving very weak signals. The mixer stage is aiso a dual-gate MOSFET as it greatly reduces spurious mixing products – some by as much as 100 dB over that obtained with bipolar mixers. A bipolar oscillator using 3rd or 5th overtone plug-in crystals is followed by a harmonic bandpass filter, and where necessary an additional amplifier is used to assure the correct amount of drive to the mixer. Available in your choice of input frequencies from 5–350 MHz and with any output you choose within this range. The usable bandwidth is approx. 3% of the input frequency with a maximum of 4 MHz. Wider bandwidths are available on special order. *Although any frequency combination is possible* (including converting up) best results are obtained if you choose an output frequency not more than 1/3 or less than 1/20 of the input frequency. Enclosed in a 4-3/8" x 3" x 1-1/4" aluminum case with BNC receptacles, power and antenna transfer switch. Thousands of our converters are now in use by satisfied customers, many of whom are government agencies and universities.

Model 407 price: 5–200 MHz $42.95
201–350 MHz $44.95

Prices include .005% crystal. Additional crystals $5.95 ea.



UHF 20 dB MIN. GAIN 3 to 5 dB MAX. N.F.

This model is similar in appearance to our Model 407 but uses 2 low noise J FETS in our specially designed RF stage which is tuned with high-Q miniature trimmers. The mixer is a special dual-gate MOSFET made by RCA to meet our requirements. The oscillator uses 5th overtone crystals to reduce spurious responses and make possible fewer multipliers in the oscillator chain which uses 1200 MHz bipolars for maximum efficiency. Available with your choice of input frequencies from 300–475 MHz and output frequencies from 14–220 MHz. Usable bandwidth is about 1% of the input frequency but can be easily retuned to cover more. This model is now in use in many sophisticated applications such as a component of a communications link for rocket launchings.

Model 408 price $51.95
.005% crystal included.

VHF FM RECEIVER
11 CHANNELS • 135–250 MHz

● 11 crystal-controlled channels. ● Available in your choice of frequencies from 135–250 MHz wide. ● I.F. bandwidth (channel selectivity) available in your choice of +/–7.5 kHz or +/–15 kHz. ● 8-pole quartz filter and a 4-pole ceramic filter gives more than 80 dB rejection at 2X channel bandwidth. ● Frequency trimmers for each crystal. ● 2 to 3 μvolt for 20 dB quieting. ● Dual-gate MOSFETS and integrated circuits. ● Self-contained speaker and external speaker jack. ● Mobile mount and tilt stand. ● Anodized alum. case, 6" x 7" x 1-3/8"

Model FMR-250-11 price: 135-180 MHz $109.95
181-250 MHz $119.95

Price includes one .001% crystal. Additional crystals $6.95 ea.

HOW TO ORDER:

All the preamps on this page are available only from Vanguard Labs. For receivers and converters, state model, input and output frequencies and bandwidth where applicable. Remit in full, including sales tax if you reside in New York State, direct to Vanguard Labs. Prices include postage by regular parcel post. For air mail or special delivery include extra amount; excess will be refunded. Send money order or certified check for faster shipment.

the CW EXcavator

Digging signals out of the noise was a problem when Hertz made his experiments, and it's still a problem when we communicate with the astronauts. It's not just your QSO's that fade into the noise or get buried in the confusion. It only seems that way. One of the best tools for digging out a signal is a filter with a response that just matches the spectrum of the signal. The closer the match the better the digging. The CW excavator is an audio filter that really digs a signal out of the mud, and does it without ringing like a bell.

A filter that matches phone signals is nothing like a match for CW signals. A phone signal has a bandwidth of about 2.5 kHz to 2.8 kHz, while a CW signal has a bandwidth of less than 50 Hz. The actual bandwidth is directly proportional to dotting speed, and when the going gets tough most operators slow down so that the actual bandwidth required for communicating drops. Consequently, a receiver with a beautiful response for phone has a bandwidth more than fifty times wider than necessary for CW signals. When your QSO is the only one going, the extra bandwidth may not hurt much, but when the band is crowded it makes more than 50 more chances for interference. That is a lot of unnecessary QRM.

Ideally, only the signal within the filter's passband should be heard; all other off-frequency signals should be completely attenuated. A real world filter attenuates the off-frequency signals, but not completely. Fig. 1 shows how several typical filters perform. The dotted curve results from a single resonant circuit with a Q of ten tuned to 800 Hz. The 3 dB bandwidth is 80 Hz but the 40 dB bandwidth is 8000 Hz. If the Q were increased to 20, the 3 dB bandwidth would decrease to 40 Hz and the 40 dB bandwidth would decrease to 4 kHz off-frequency.

The dashed curve in Fig. 1 shows the result of cascading a similar resonant circuit with Q of 10 and also tuned to 800 Hz. The second cirsuit really helps. Increasing the Q of both circuits to 20 reduces the 3 dB bandwidth to 25 Hz and the 40 dB bandwidth to 400 Hz. This represents a big

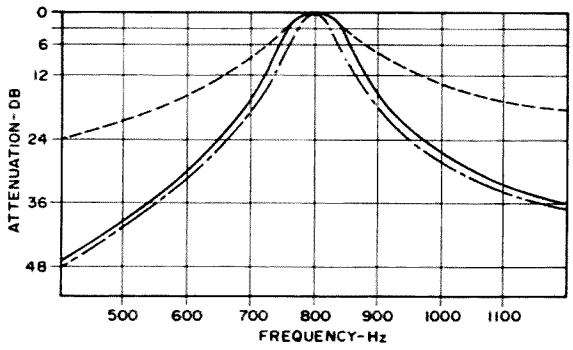

Fig. 1. Response of one and two tuned circuits.

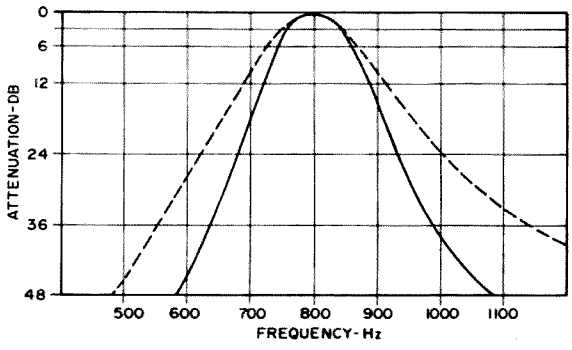

Fig. 2. Response of four stages.

improvement in cutting QRM but tuning and receiver stability become much more demanding and you may even notice a bell-like quality in the signal. Even a 50 Hz bandwidth makes receiver tuning touchy, and if your receiver is a little drifty, keep your transmissions short.

There is a way to have your cake and eat it too. Relatively high Q circuits tuned to slightly different frequencies increase the 3 dB bandwidth without giving up too much off-frequency attenuation. The solid curve in Fig. 1 results when two tuned circuits are stagger tuned; that is, one is tuned to a frequency above 800 Hz while the other is tuned below 800 Hz. The tuned frequencies are 772 Hz and 828 Hz and the Q's are 14. The 3 dB bandwidth, 80 Hz, is as wide as a single circuit with Q of 10 but the skirts are about as steep as two stages.

Since two tuned stages are better than one, and stagger tuned is better than synchronous tuned, we might conclude that the more stagger tuned circuits the better. They are – if they are on the right frequency and the Q's can be achieved. The CW Excavator uses four tuned stages arranged to form two staggered pairs. Fig. 2. compares the response of two staggered pairs, the solid curve, to four synchronously tuned stages; that is, four stages all tuned to the same frequency of 800 Hz. In both cases the 3 dB bandwidth is arranged to be 100 Hz.

To avoid the problems of tuning and loading coils and maintaining the proper impedances, the CW Excavator uses active filters. The active filter achieves the effects of L and C with R's and C's and an operational amplifier. Unlike the LC resonant circuit, the active filter is relatively immune to load changes, and it can provide gain as well. Although the CW Excavator has limited power output, it can easily drive a pair of high impedance phones.

The schematic of the CW Excavator, shown in Fig. 3, may not look like a filter so let's take it apart and see how it works. The componenets shown within area "B" make an active bandpass filter 85 Hz wide tuned to 756 Hz. The components within area "A" make an active bandpass filter 93 Hz wide tuned to 844 Hz. These two stages make a staggered pair with a bandwidth of 125 Hz centered at 800 Hz. Cascading two such pairs produces a filter with a 3 dB bandwidth of 100 Hz centered at 800 Hz. The theory behind the active filter is rather new and the derivation of the working equations is quite involved. Fortunately the qualitative description of an active filter is straightforward, even though the quantitative analysis is something else. Basically, the active filter is a feedback amplifier in which the magnitude and phase of the signal fed back determine the overall frequency response.

A brief discussion of the workings of a feedback amplifier will help in understanding the active filter. The block diagram, Fig. 4, shows a general amplifier. For the sake of discussion, the amplifier is assumed ideal: The input impedance is very high; that is, no significant signal current flows in the input. The gain of the amplifier is very large. The output of the amplifier is exactly out of phase with the input. The output impedance is very low; that is, the output voltage is independent of the load. Since the voltage gain is very large, a minute voltage, e, at the input causes a very large output voltage. Since there is no signal current flowing in the input of the amplifier and the voltage e is essentially zero, the current I m must be

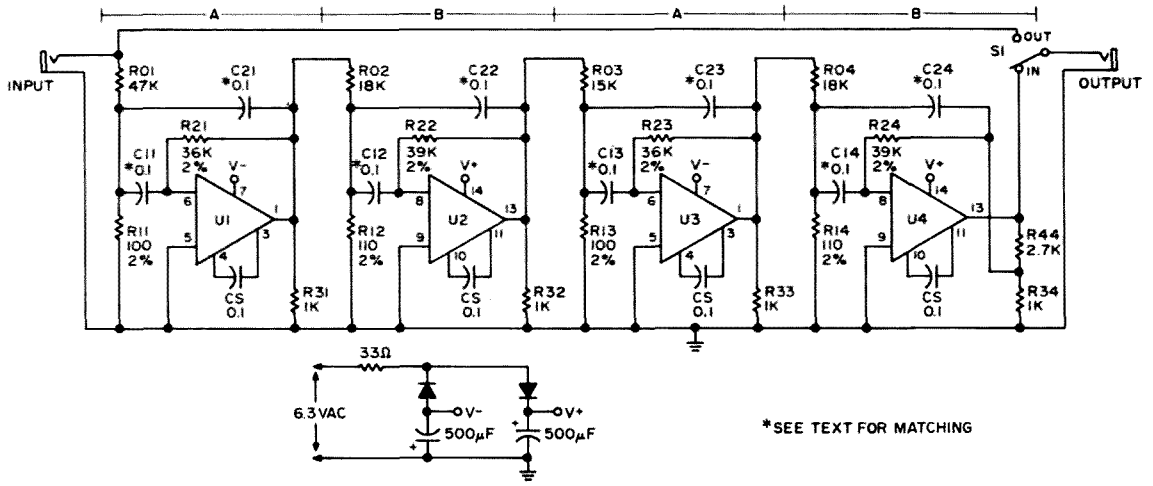

Fig. 3. CW Excavator.

equal and opposite to the current Ifb. Consequently, the voltage gain may be expressed as:

$$G = \frac{E_O}{E_S} = \frac{Z_{fb}}{Z_{in}}$$

If Zfb or Zin vary with frequency, the gain of the amplifier with feedback will vary with frequency. The IC operational amplifier fills the requirement of gain block so the secret of designing active filters reduces to designing feedback networks that vary with frequency in a prescribed way.

A qualitative description of the active bandpass filter shown in Fig. 3 area A is typical of all four stages. R11, R21, C11, and C21 make up the frequency sensitive feedback network around the operational amplifier U1. Cs and R31 stabilize the amplifier so that it can not oscillate under any feedback conditions. R01 and R11 form a voltage divider that sets the gain of the stage. The first stage is arranged to have a loss of 10 dB, the second and third stages have unity gain, and the fourth stage has a gain of 10 dB. Consequently, the overall gain is about one. R34 and R44 increase the gain and maximum output level of the amplifier while maintaining an acceptable feedback level.

At very low frequencies the reactance of C11 is large compared to R21 and the voltage gain is low. At very high frequencies the reactance of C21 is low compared to R11 and the gain is again low. At some in-between frequency the reactance of C21 is large compared to R11 and the reactance of C11 is small compared to R21. Consequently, the voltage gain is high at this in-between frequency. Specifically, the frequency of maximum gain or center frequency of the passband is:

$$f_{01} = 1/2\pi\sqrt{R_{11}R_{21}C_{11}C_{21}}$$

The maximum gain, relative to the voltage across R11, is:

$$G_{11} = R_{21}C_{21}/R_{11}(C_{11} + C_{21})$$

The 3 dB bandwidth is:

$$B_1 = 1/2\pi R_{11}(C_{11} + C_{21})$$

In designing an active bandpass filter, any absolute values of R or C can be used that satisfy the above equations. If you need a special audio filter for your RTTY or repeater control experiments, these equations should put you on your way. Since odd values of resistors are more readily available than odd values of capacitors, pick a standard capacitor value and go from there. The calculations may be laborious but they are straightforward. These are the steps in calculating the values of any particular filter.

1. Calculate the product R1 and R2 from the chosen values of C1 and C2 and the desired frequency.

$$R_1R_2 = 1/(2\pi f_0)^2C_1C_2$$

2. Calculate the value of R1 from the desired bandwidth and the chosen values of C1 and C2.

$$R_1 = 1/2\pi B_1(C_1 + C_2)$$

3. Calculate the value R2 from the R1R2 product obtained in step 1 and the value of R1 obtained in Step 2.

$$R_2 = R_1R_{2/R_1}$$

4. Calculate the gain from the values of R1, R2, C1, and C2.

$$G_1 = R_2C_{2/R_1(C_1 + C_2)}$$

5. Calculate the value of R0 from the desired gain, G0, and the value for G1, and R1 obtained in Steps 2 and 4.

$$R_0 = R_1(G_1 - G_0)/G_0$$

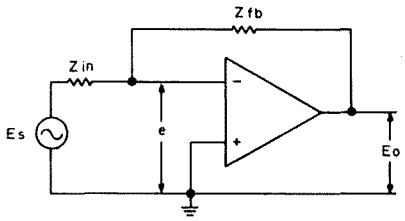

Fig. 4. General feedback amplifier.

If you are designing a new filter remember that the calculated value for R1 results from paralleling the physical R with R0 in series with the input's source resistance.

The effects of component variation and tolerance on the individual stage, and consequently, on the overall filter performance, are rather critical. Center frequency, bandwidth, and gain all vary with R1, R2, C1 and C2. Gain variation is not particularly important since it doesn't effect the filter's performance in digging signals out of the bedlam. On the other hand, only small variations in center frequency can be tolerated. In general, increasing the frequency separation of the stages making up the staggered pair increases the overall bandwidth and produces a double peaked response. Decreasing the bandwidth of the individual stages also produces a double peaked response. Reducing the frequency separation of the stages reduces the overall bandwidth and produces a single peaked response. Increasing the bandwidth of the individual stages increases the overall bandwidth and also produces a single peaked response. The stage bandwidth variation caused by gross component tolerances barely effects the overall response. For example, reducing the stage

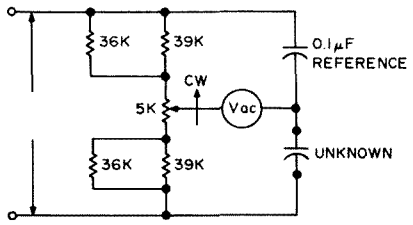

Fig. 5. Comparison bridge.

bandwidth to half only causes 2 dB peaks and a bandwidth change of about 7%. The center frequencies of the individual stages in the staggered pair and are very critical and normal component tolerances result in drastic performance changes. For example, if either R1, R2, CI or C2 were 10% low, the center frequency would be 10% high. If this were the high frequency stage, the peak would shift from 844 Hz to 928 Hz. If one of the components in the low frequency stage were 10% high, the center frequency would shift from 756 Hz to 670 Hz. The bandwidth of the pair would consequently be about 250 Hz. Obviously, steps must be taken to make sure the stages are tuned to the proper frequencies.

One way to put the stages on-frequency makes R2 variable, but that requires an audio generator that can very accurately set to frequency. Using close tolerance parts avoids the problem but the availability and cost may rule out that solution. A compromise uses semi-precision resistors with 2% tolerances and ordinary mylar capacitors with 10% tolerances. The capacitors used in a particular stage are paired so that their product is near 0.01×10^{-12} to put the stage on-frequency. As a consequence of this pairing, the sum is also very near the desired 0.2 μF required to produce the proper bandwidth. The secret is to pair a high plus tolerance with a high minus tolerance and a low plus tolerance with a low minus tolerance.

If you have access to a good capacitance bridge and a stock of 0.1's you've got it made. Even if you don't have a big stock of capacitors and don't have a bridge, there is a way out. With twelve 0.1 μF's required for the complete filter, the laws of probability favor your finding four good pairs. The problem is to find which capacitors are relatively high and which are relatively low so they can be paired. The technique I used

doesn't take special equipment, just time and patience. A 5K pot, and an ac voltmeter plus the parts needed for the filter can be used to make a comparison bridge.

The relative capacity of the 0.1 μF's can be determined by temporarily using the semi-precision resistors as part of a bridge as shown in Fig. 5. The meter used to detect the null can be either a VTVM or a 5000 Ω per volt meter with a 3V range. The pot should have a linear taper just to make life easier, and a dial or pointer on the shaft helps in judging the relative position of the pot's arm. Arbitrarily pick any one of the 0.1μF's to use as the reference in the bridge.

The procedure for determining the relative capacities is as follows: Connect the capacitor to be evaluated into the "unknown" position in the bridge and adjust the pot for a null on the meter. The farther CCW the arm is from mid-position the samller the unknown capacitor is relative to the reference capacitor. Measure each of the capacitors and identify them according to their relative capacity. To determine the location of the reference capacitor in the overall order, replace it with the smallest measured capacitor and repeat the measurement.

Matching the capacitors is essential to making a filter with predictable characteristics. If the dial on the pot doesn't provide much resolution, use the following method to recheck the capacitors. Check the capacitors in increasing order of capacitance and note that the pot must be turned a little more CW to null each capacitor. If the pot must be turned CCW to null, the capacitor being measured is smaller than the one previously measured. After the capacitors are arranged in order of capacitance, they can be paired.

The two largest and two smallest capacitors are used as the stabilizing capacitors, Cs (Fig. 3). Only the middle eight capacitors are used in the frequency sensitive feedback networks. Of these eight capacitors, pair the largest with the smallest, the next largest with the next smallest and so on. Use any pair in any stage of the filter; that is, $C_{1\_}$ and $C_{2\_}$ must be a pair.

Power for the unit is not critical; the supply shown as part of Fig. 3 need not be used if you have other sources. Any supply voltages between ±5 volts and ±15 volts can be used, and they need not be balanced. The current drain is only 8 mA with 6 volt supplies and about 20 mA with 15 volt supplies. Ripple on the supplies can be pretty high without adverse effect; the supply shown in Fig. 3 has about 0.25 volts ripple and there is no detectable hum in the output.

Any construction technique can be used, the layout is not critical. In fact, the leads to the filter bypass switch S1, need not be shielded. I put my filter on a 2" x 5" piece of Vectorboard in a min-box. I used μA739's because that's what I had, but the 709 should work as well. If you want to use 709's, remember to stabilize the amplifier for unity gain; for the 709A that would be 5000 pF in series with 1.5K between pins 1 and 8, and 200 pF between pins 5 and 6.

There is no trick to using the filter but its extreme skirt selectivity can produce some puzzling effects until you think about it awhile. For example, with the filter "in," you can't tell when the receiver or filter are overloaded. The great selectivity rejects the distortion products, so there is no change in the sound of the audio, even under severe overload. The only solution I've found is to reduce the receiver's gain until the output is obviously less than maximum. With my 2000Ω phones the maximum output is uncomfortably loud, so I know that a comfortable level is below overload.

The effects on a phone signal may cause some head scratching too. The gain of the filter is about unity for 800 Hz, so there is little change in the level of an 800 Hz note when the filter is switched "in" or "out," but a comfortable level signal with filter "out" The reason: the energy in the 750 Hz to 850 Hz segment of the phone signal is very small compared to the total energy. This is probably the most dramatic demonstration of the CW Excavator's ability to reject off-frequency signals and cut the QRM.

If you want to dig CW, the CW Excavator is the tool. It will improve a good receiver and give an ordinary AM or SSB receiver CW selectivity that is as good as any. If the QRM discourages you, build the CW Excavator and be prepared for a change.

ANTENNAS and TEST RECEIVERS for 1296, 2300 and 3500 mHz

Using the oscillators described in 73[1] along with the diode receivers described here, it is possible to set up a working UHF amateur station for the 1296, 2300 and 3500 MHz amateur bands. The oscillators first will help you tune the antenna and receiver, then will work as a transmitter and as a local oscillator for superhet receiver operation.

The 1296 Diode Receiver

At this frequency you should begin to take care or you won't finish up with a good tunable receiver. The following notes and precautions should help you to line up a workable unit for the band.

1. Looking at Figs. 1A, B, C and D, the nylon bolts used for tuning and adjusting screws must be held firmly by a bakelite or other insulating strap that uses two bolts, as in detail in Fig. 1C.

2. The spacing of L1 to the baseboard should be small.

3. C1 should be made up with care, as in detail shown in Fig. 1C, keeping in mind that the inductance of the movable tab part of C1 should be as low as possible. You could use penny tuning between the baseboard and L1 but that gets more involved mechanically.

4. The adjustable input coupling capacitor C2 should be made up as in Fig. 1D, which shows one continuous piece of spring copper strap from J1 over to the movable part on top of L1.

5. Again, the diode must be a good one. I haven't had much luck with UHF diodes such as 1N82's and the like. The TV and radio people furnish some dandy low-cost

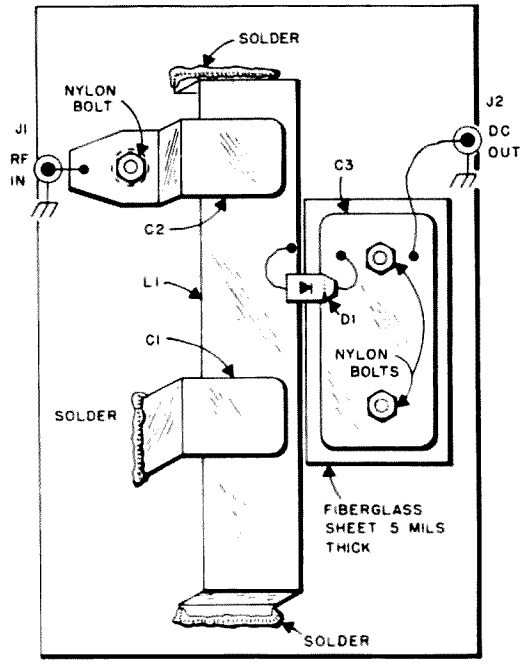

Fig. 1A. Top view of the 1296 MHz diode receiver. L1=2 1/4" long, to first bends (top); 9/16" wide brass strip; C1 = spring copper strap, 1/2" wide, top part 3/4" long, vertical section 1/4" long; C2= spring copper strap, 3/8" wide, part above L1 1/2" wide; C3= brass plate, 1" x 1/2".

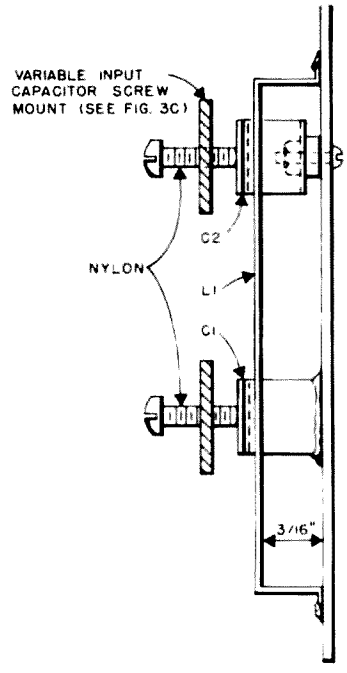

Fig. 1B. Side view of the 1296 MHz diode receiver.

items for us amateurs, but if they make a diode good for channel 83, that's as far as it will go. It may just meet a spec (one of which I've seen called for a noise figure of 14 dB for 890 MHz) and be practically worthless for 1296 MHz amateur use. Use a good X band diode, and you won't have that item to worry about.

That about does it for this little 1296 MHz plank. The size suits a minibox and it will start you off on 1296, checking power out of oscillators, antenna tuneup, frequency measurements, antenna gain by the distance method, etc.

The 1296 MHz Standard Test Antenna

A little scaling down, dividing by three, and a snip here and there with a dentist's tin snips, and I soon had two antennas ready for test.

Using the oscillator previously described, and the 1296 MHz diode receiver with the half wave line just detailed, the test system of Fig. 2 was set up. The meter began to move and the antenna tuning was started in the same manner as in the 432 MHz procedure. However, things don't always work that easily. There didn't seem to be any great amount of "soup" around the room. The new receiver was checked against a

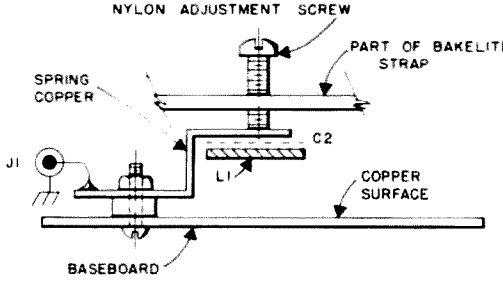

Fig. 1C. End view of the 1296 MHz receiver and C1 detail.

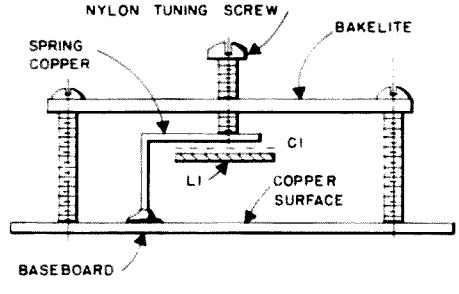

Fig. 1D. Side view of the 1296 receiver, and detail of C2.

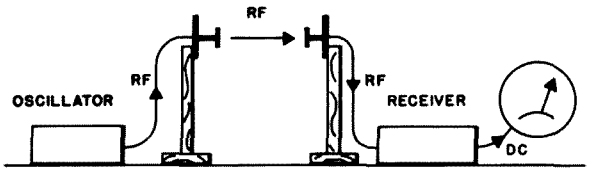

Fig. 2. Test setup.

couple of others using cavities, and straplines in rectangular boxes, and was found to be their equal for dc output for a given amount of rf. It was just this rf that didn't want to "give." All kinds of chokes in the emitter and other arrangements were tried in the 1296 MHz test oscillator to bring up more power, but to no avail. I finally had to resort to taking out the Motorola HEP56 transistor and putting in a KMC H104. The HEP56 shows good power on 432, lights a bulb and all, but on 1296 MHz it just doesn't seem to cut the mustard. After all, it's only $1.50 and it wasn't made for 1296 MHz use.

The KMC H104 does the job though, and there is one other item I found while working on the oscillator to bring it up to maximum power. I have referred several times to a sliding short under the collector strapline L1, for rough tuning. It does that all right but for maximum Q, starting oscillation every time, and trying for maximum output into small test antennas it appears to be better to cut L1 to the desired length and solder it down tight to the baseboard. The high rf currents and extreme low impedance at the ends of the half wave line L1 demand good soldered and wide-strap joints in order to have the highest Q.

Tuning can then be done by changing L1's spacing from the baseboard, with higher frequencies resulting from closer spacing. Further tuning can be achieved by using the grounded tab type of tuning capacitor shown as C1 in the following Figures, and used on the 1296 MHz receiver described.

Getting back to the antenna tests, now that good oscillator power was achieved, Fig. 3A shows the top view and Fig. 3B the front view of this convenient piece of test equipment for the band. It is of the same general type as the 432 MHz antenna described earlier but you will have to pay more attention to details, such as keeping the

the **Incomparable**

by **CX7A**

signal/one

Features:

- RELIABILITY IS NOW standard equipment. Every CX7A "burnt-in" and cycled more than 96 hours.
- QUALITY-PLUS. Every component is instrument grade. American-made, and individually tested.
- ALL MODES 10 thru 160 meters in full 1 MHZ bands with overlaps.
- BROAD-BAND TUNING. Instant band changes without tuning.
- TRUE BREAK-IN CW with T/R switching.
- IF SHIFT – deluxe QRM slicer.
- PRE-IF NOISE-BLANKER that really works.
- RF ENVELOPE CLIPPING – sounds like a Kw.
- TWO VFO'S Transceiver Plus receiver.
- BUILT-IN: Spotter, FSK shift, transmit offset, wattmeter, SWR meter, electronic CW Keyer.

Specifications:

- SENSITIVITY: Better than 10db signal-plus-noise-to-ratio for .25 microvolts at 28 MHZ.
- SELECTIVITY: 2.4 KHZ @–6db, 1.8:1 (6:60db) shape factor. (16 pole crystal lattice Filters)
- optional: CW-300 and 400 HZ. FSK-1200 HZ.
- CARRIER and unwanted sideband suppression. Minimum 60db.
- IMAGE and IF REJECTION: more than 60db.
- POWER LEVEL: 300 to 500 watts p.e.p. continuous duty cycle.
- POWER AMPLIFIER: 8072 final completely broadbanded driver and final. 150 watts continuous dissipation rating.

reflector sheet rigid, adjusting C2 correctly, and finding the best value for D, the spacing between radiator and reflector.

C1 is made by tapping the copper-clad reflector sheet and installing a shiny new brass 6/32 bolt two inches long, which you can get in most household hardware stores now by paying about 10¢ a piece, putting a locking nut on it, and soldering the nut to the reflector copper sheet after adjusting for the desired locking tension. On the end of the bolt facing the radiator solder a brass nut and file it flat. This makes up C1 which is tuning good now, and is spaced about 1/8th in. from the radiator, using the dimensions of Figs. 3A and 3B.

Any flexibility in the reflector sheet makes it difficult to tune up with C1, which is of course sensitive to any changes in its spacing. Use thicker copper-clad, a wood backing, or a nylon bolt between the radiator and the reflector to hold it in an exact and steady position.

That should get you started on the air, at least across the room. It's not as easy as all

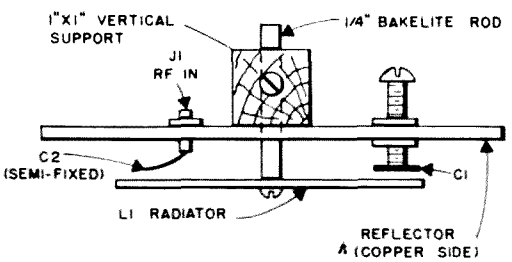

Fig. 3A. Top view of the 1296 MHz test antenna. Spacing, L1 to reflector – 3/8"; C2 to center of radiator – 3/4"; length of L1 – 3 5/8".

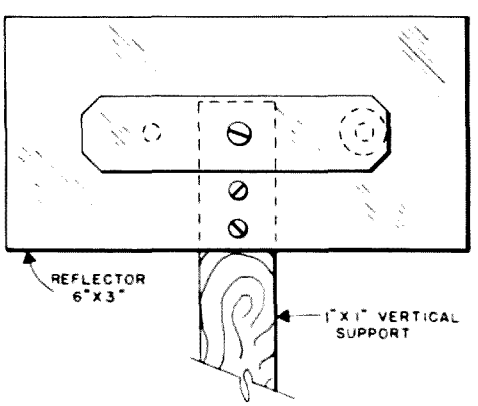

Fig. 3B. 1296 MHz test antenna, front view.

that every time, though. You can light off the oscillator, it shows power, with the H104 transistor collector meter dipping on 1296 oscillations like the good old tubes used to do on five meters, hook up one antenna to the oscillator, the other to the receiver, face them up across the bench, throw the "On" switch, and the receiver output meter may not even budge.

This has happened several times here, so don't worry. Providing you have built the four items mentioned as described here, it just means that one or more of them are not on frequency. Remember, that's four items to be on frequency. The same frequency. Recheck the receiver and transmitter frequencies with a cable and loose coupling, put the antennas close together, almost touching, and the receiver should take off. As mentioned above, don't worry, it will eventually. It's one of the laws of nature! One part of that law just happens to require that all those four items must be on the same frequency, or close. How close, you'll soon find out.

This 1296 MHz band is a real transition for antennas. The two-element job herein can start you off on tests. Then you can reduce the size of the reflector and point the assembly into a skeletonized parabolic dish (see Lafayette Radio, $16 for a five footer, $26.50 for a seven footer – I'm only reading out of their catalog). You may have to cover the reflector rods with copper or aluminum screen though, because, once again, those TV lads have it tuned up for 890 MHz only, channel 83. After that, the higher frequencies may start to leak through those too widely spaced rods.

You can also rig up nice compact phased arrays, and such.

Receiver 2300 MHz

This little gem is quite similar to the 1296 job, with everything a little smaller. Figure 4 shows the layout. While L1 shows as only 35 millimeters, or 1 3/8 in. long, don't forget that the bent down or vertical portions of L1 counts also, making L1 35 plus another 12 millimeters, for a total length of 47 millimeters. This works out to be near 7/10ths of the half wavelength, which is

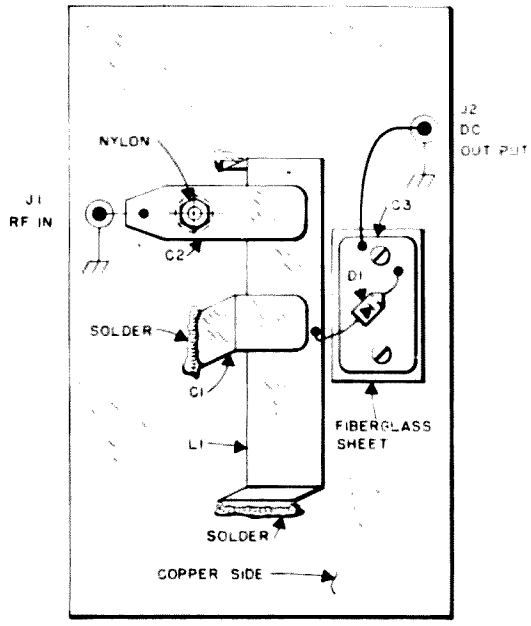

Fig. 4. Diode receiver for 2300 MHz. L1 = 1 3/8" long on top, spaced 4 mm (5/32") from baseboard; C1 and C2 adjusted by nylon bolts as in the 1296 MHz receiver.

reasonable enough considering the parallel capacitor C1, and the shunt diode D1. For the rest, pay attention to the items as listed for the 1296 job and you should be in tune with the 2300 MHz oscillator.

This is the band where parabolic dishes really begin to show power gains. Just a hint – we tested an old 23 in. aluminum dish which has been carried in our 45 ft junkbox since the good old Canal St., NY, surplus days of the late '40s, and found a gain of around 144 times a dipole. See what I mean?

Just in case I didn't mention it lately, I use a 50 microamp meter on the receiver dc output, again, Lafayette Radio, $4.75, with a switch for times one, times 10, and times 100. You can also set it up to read .5 and 5V if you like. Beyond that voltage, better watch those $3 diodes! Or just move the antennas further apart. Or cut down on the oscillator power with that emitter pot I keep talking about.

This frequency is part of the S band of microwave radar and I consider it to be past the transition stage and well into the field of parabolic reflectors, although my favorite antennas, the lenses, don't show up in a startling fashion till we reach the X band (You know by now, just keep reading!)

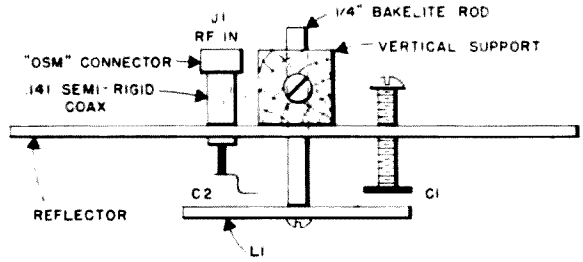

Fig. 5. Test antenna for 2300 MHz. L1 is copper strap, 1 13/16" long by 3/8" wide; reflector is 6" by 3"; spacing of L1 to reflector is 5/16"; distance from C2 to center is about 3/8" (should be maximized on test).

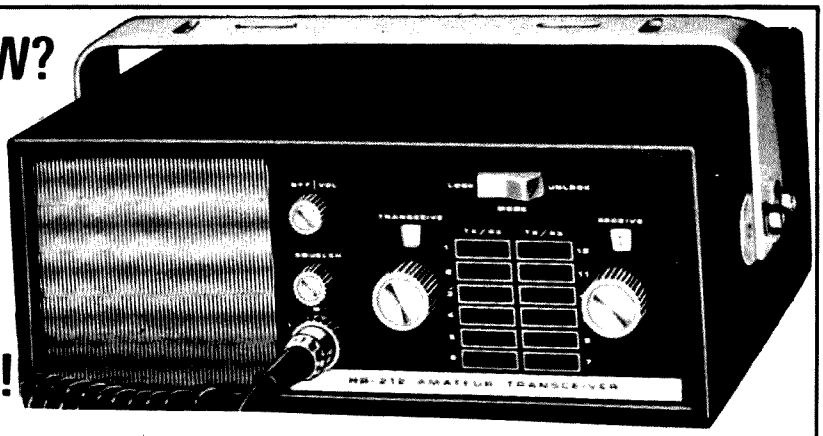
Test Antenna 2300 MHz

Just for fun, as I look at the 1296 and the 2300 MHz antennas on their little walnut test stands (I happen to live near an instrument case manufacturer) in front of me, the ratio of the lengths of their radiators was checked against the ratios of their frequencies, to see how the scaling down was progressing.

The 1296 MHz radiator L1 is 91 millimeters long, and the 2300 one is 46, which is almost exactly double. But twice 1296 is 2592, so there is probably a shortening factor working there somewhere. Let's check the 3500 MHz antenna, to jump ahead a little. It is 32 millimeters long. Three times 32 is 96 millimeters, close to 1/3rd of the 1296 MHz antenna length, and three times 1296 is 3888 MHz. Works out fairly close. With C1 operating in shunt, you probably could scale them exactly, although there are other factors, like the width of L1, end effects, etc. Just interested, so assume you might be also.

Figure 5 shows the details of the 2300 MHz test antenna. I used .141 in. OD semi-rigid coax for the cable input, and chickened out with an OSM connector instead of a phono jack. After all, this is microwave frequency! I'm still working on the idea of a low-cost connector for you (and me too).



To use this antenna as a feed to work into a parabolic dish for high gain, cut down the size of the reflector sheet, as your energy coming out of the dish has to go out forward past the primary feed. See Fig. 6 for diagram of element placement.

With gains of well over 20 dB for a 23 in. dish, you can begin to see some reasons for

DID YOU KNOW?

Regency's HR-212

IS DIFFERENT!

At the flip of a switch you have a choice of 2 modes of operation:
1) 12-channel transceiver with transmit and receive frequencies controlled by one knob.
2) 12-channels with one knob controlling transmit channel and a second knob controlling the receive channel independently.

Either way you have 0.4 mv sensitivity and 20 watts of power. We will install & set your choice of frequencies at $3.95 per crystal & ship immediately. Our own AC supply available $19.95.

this band. Think about radar on your present license, DX from mountain tops with the battery supply for these rigs, etc.

3500 MHZ Receiver

Here I chickened out again. Not for long though. It's just that here is another transition region, this time between open-air strapline and enclosed coaxial cavities.

It's a real project to make a comparison between the two methods and that will be another story.

So, for the time being, I used the diode-equipped coaxial wavemeter, as a receiver for this frequency. It works very well of course, but the coaxial tuner part is a little difficult for the homebrewer to make. I hope to have some of these made up, but this may take a while. Maybe you'd want to jump all the way to X band anyway?

Figures 7A and 7B show the layout of the top side, and some inner details for reference. This piece of equipment can be very useful. It measures frequency from 1 to 12 GHz, and makes a nice mixer for those frequencies also. And a diode test receiver for uses such as the present one being described.

What more can I say about it? There is a tremendous world of microwaves for amateurs ahead of us. We have the bands, at least today, and now with $5 transistors we can make battery portables to use them. Let's go!

3500 MHz Test Antenna

As mentioned earlier, oscillator for the 3500 MHz amateur band, you may not need this band for a few years, but it is interesting to see how it works, so a test antenna was built and tested.

About two millimeters was trimmed off one end during tuneup and it is now operating with plenty of "sock" using the oscillator mentioned above.

Figure 8 shows details with everything about the same as at 2300 MHz except that it was about half the size, and I dropped down to a 2/56 size bolt for the tuning capacitor C1, and had to cut off a portion of the one-by-one red cedar vertical mounting stand to install J1.

This little firecracker pût out a lot of power into the room, but some of that may be due to the $200 Fairchild transistor! ($50 in *steady*, 1000 lot purchases)

Just a little touch of trouble while tuning up the 3500 mHz antenna. Not with the antenna, though. The oscillator has an OSM connector on it, and I wasn't getting any rf

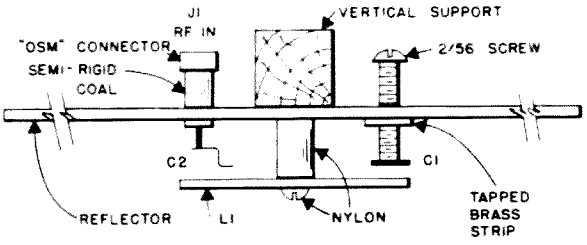

Fig. 8. Test antenna for 3500 MHz. L1 is a copper strap, 1 9/32" long by 1/4" wide; distance of C2 from center is 5/16"; spacing L1 to reflector is 3/16"; reflector size is 4 1/2" by 2 1/2".

out at all, although I could see by the collector meter that it was oscillating strongly. All of a sudden the center of the connector fell out in my hand. I unsoldered it, pushed it way in tight, resoldered a pickup loop back on, and wham over to the pin went the meter. It happens!

Have fun with this one, too, if you can afford it. I can't really myself, so will stick to 432, 1296, and maybe pulse on 2300 mHz for now.

Frequency Measurements With The Interferometer

Admittedly, in order to make frequency measurements by this method you need an oscillator, receiver, and two antennas. And in order to have these you need a frequency meter. Cheer up, it's not quite impossible. The main purpose here is to start you off with just those items. With the dimensions given you will be able to tune up somewhere near the desired band and then by using the simple interferometer method described you can put your oscillator near the middle of the band and go on from there.

The interferometer itself dates from several hundred years back, long before Maxwell or Hertz, and has some good solid basic features to recommend it.

1. It measures the length of your oscillator's waves right out in the open air which, although not precisely a vacuum as in free space, is so close in wavelength that you or I could not possibly check the difference.

2. Thus you do not have a wire velocity factor to account for.

3. You can perform this measurement right on your bench-top.

4. For equipment all you need besides the oscillator, receiver, and the two antennas, is a couple of plane sheet reflectors which can be 10 x 10 in. aluminum chassis, or similar, standing on end on the table, a 10¢ plastic ruler, and the frequency-wavelength chart of Fig. 10.

Steps to follow

1. Set up as shown in Fig. 9, "Frequency measuring setup for 432, 1296, 2300, and 3500 MHz."
2. Put reflector A and B in the same plane and about 3 or 4 ft from the transmitter and receiver, which should be close to each other but pointing toward the reflectors.
3. If you're using some power and your receiver is sensitive enough you may need some nonreflecting material between the T and the R. Normally you don't, but it's handy to have around anyway.
4. Set up the T and the R so that an equal amount of power falls on reflectors A and B, and so that an equal amount of power comes back to R, the receiver. You can tell when this is so by a good sharp null on the receiver meter when operating.
5. Leaving A fixed, move B toward T and R keeping its surface parallel with that of A. At the half wave point there should be a deep null with R's meter dropping to zero.

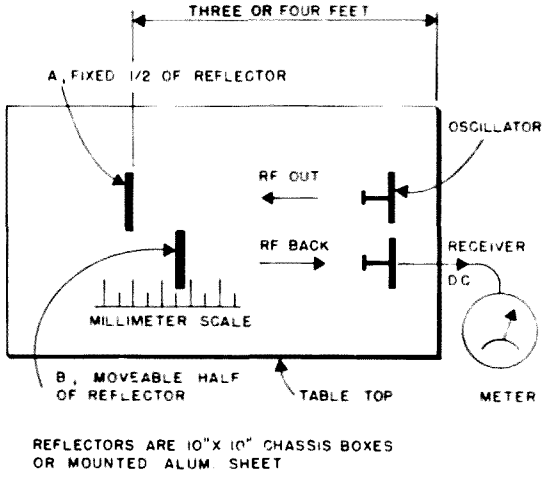

Fig. 9. Frequency measurement setup and interferometer details.

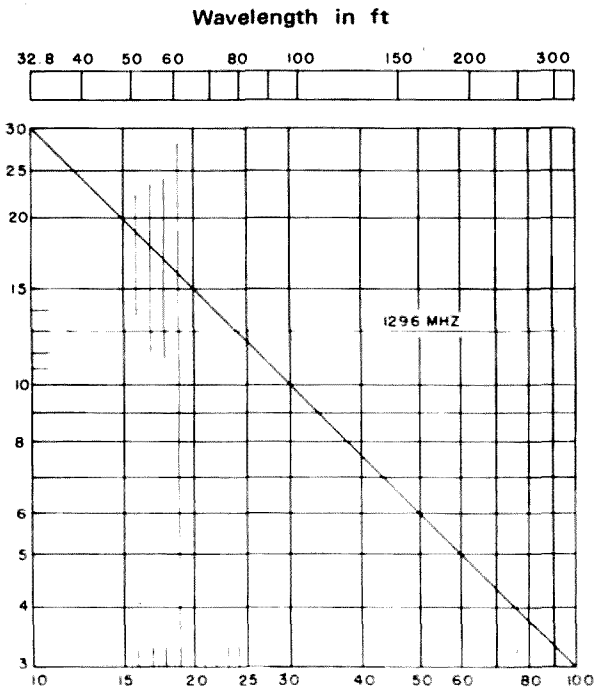

Fig. 10. Chart illustrating the wavelength frequency conversion.

6. Repeat the process several times, continuing to move B a number of half waves toward T and R, taking millimeter readings along the scale at each null.
7. The average spacing between nulls, in millimeters, will be the half wavelength. Convert to frequency with the chart of Fig. 10, or use a conversion factor if you wish. For instance the frequency in cycles per second equals 300,000,000,000 divided by the wavelength in millimeters. For example, 10 centimeters, which is 100 millimeters, equals 3,000,000,000 cps, or, 300 MHz, or 3 GHz. That's it. Happy millimeters.

Just about everything has been said, for a room-type start on solid state amateur UHF and microwaves for the average amateur to get going, and, as soon as he converts to a superhet receiver, work long distances from those hilltops with just a lantern battery for power. Think about interstate relays using this method.

An interesting feature of these bands is the geographic separation provided by two sharp high gain beams, from 23 in. dishes, pointed at each other. Who can butt in?

BALUN UP or BALUN DOWN?

The use of the balun, now that these are available in small and fairly inexpensive forms, is becoming more and more common, and the question of whether the balun should be placed in the center of the driven element itself and the feed line from there on consisting of a coax, or whether the antenna should be fed with twin lead and the balun used at the bottom in the shack, becomes a question of some importance.

It might, therefore, be worth analyzing the advantages and disadvantages of the two systems. Figure 1 shows the balun at the top in the antenna itself. There are two advantages to this setup: 1) Simplicity, it eliminates the central insulator in wire antennas, and does not require the 72Ω feed line; and 2) The feed line can be made less lossy, as the best air-spaced coax has lower losses than 72Ω twin lead.

The disadvantages are in weight and weatherproofing. The balun with the weight of the coaxial cable usually weighs down the center of the driven element, so that it appears more as Fig. 2 than Fig. 1. It puts additional strain on the supports and, above all, lowers the center of the antenna, which, in most antennas using half wave driven elements, reduces the efficiency. Where the center can be supported independently (by a third pole or a conveniently placed tree) this factor does not apply. In the case of the inverted V which is supported in the center, obviously, this certainly does not apply.

If the balun is placed at the top in all the weather, it must be very thoroughly weatherproofed. This is especially important where the coaxial cable is connected to the balun. Not only will any water from rain, or snow, or ice which can seep into the joint, go down into the airspaced coaxial cable, but also corrosion can soon develop in the

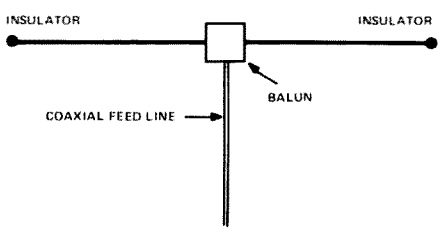

Fig. 1. The balun at the top in the antenna itself.

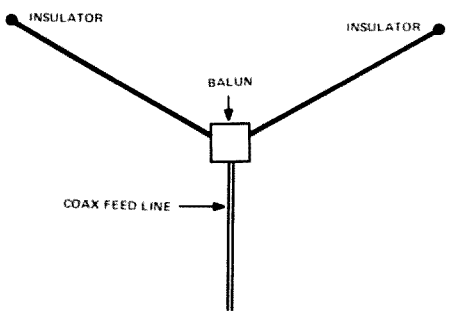

Fig. 2. The balun with the weight of the coaxial cable usually weighs down the center of the driven element.

connectors themselves, involving either frequent inspection and maintenance, or poor connections, giving rise not only to lower efficiency but, above all, to TVI problems.

Figure 3 shows the balun at the bottom, in the shack. In this case, if no central support is used, the central part of the antenna will be higher due to less weight in the center. This can increase efficiency noticeably where half wave driven elements are used. There is also less weatherproofing problem. The connection to the 72Ω feed line can be soldered to the element, then covered with a weatherproofing compound, and even slight water leakage is not likely to impair the soldered joint for a long time. The 72Ω line is waterproof. The balun with its connections are nicely in the dry in the shack, and no weatherproofing problem exists. It is nice and convenient for inspection.

But, the feed line if long can give greater attenuation. The best airspaced coaxial cable is definitely less lossy than 72Ω twin, and in the case of beams designed for 52Ω feed line, there will be a mismatch of 52 to 72, or, roughly 1.4:1 SWR. (In the case of beams, of course, the weight of the balun can be supported on the mast, though the weatherproofing problem remains.) Except in the case of beams designed for a 52Ω impedance many antennas, like dipoles, show impedances nearer 72Ω than 52Ω, in these cases an improved SWR may be achieved.

Apart from the advantages and disadvantages mentioned above, there is another problem worthy of consideration, namely TVI.

Theoretically, a coaxial line has its outer braid grounded and should, therefore, be incapable of radiating. This applies, of course, only if the SWR is 1:1 which it can only be at one spot frequency.

Furthermore, a conductor which grounded, is no longer grounded once one has travelled a quarter of a wavelength from the grounded point. In practice, this means that few outer conductors of coaxial cable are truly a ground potential for their entire length.

When I mentioned SWR of 1:1, I referred, of course, to the fundamental. How

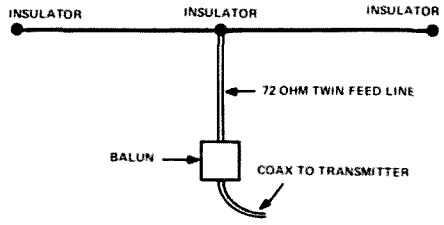

Fig. 3. The balun at the bottom, in the shack.

many feed lines show a 1:1 SWR at a harmonic frequency? Here is where a TVI problem may be created. If the outer conductor of the coaxial cable is hot to rf at the harmonic frequency, it may well radiate and cause TVI.

In the case of a twin line, the current in one leg is 180° out of phase with the current in the other leg, and they thereby cancel one another. This applies equally at the harmonic frequency as it does to the fundamental. So that the twin line gives the advantage of cancellation of any radiation from the feed line.

Of course, only in theory are the currents in the two legs of twin feed *exactly* equal and 180° out of phase. But in most cases, in practice, this is near enough effectively to reduce any radiation at the fundamental or at a harmonic frequency effectively to reduce the radiation to negligible proportions.

For the purists there is, of course, screened twin feed line – sometimes called twin coax. Here the radiation from the two legs of the twin feed line cancels out, but any slight unbalance in the current resulting in a small amount of radiation (either on the fundamental or the harmonic) is screened by the outer braid. This need not be grounded as it acts as a Faraday screen, and only has to deal with very small amounts of radiation resulting only from any possible lack of balance in the two legs of the twin line.

This screened twin feed is, however, only recommended for beams where the weight can be taken by the mast, as it is even heavier than normal coax. It is also often more lossy than unscreened twin unless very large dimensions are used. It is only mentioned here for its TVI application where I found it very effective.

In this case the balun is also at the bottom in the dry in the shack.

Another Solid State Power Supply article

Arvid G. Evans K7HKL
1005 Howard
Boise ID 83706

Over the last few years I've run the usual course in power for my low voltage projects. Everything from a string of D cells to a leaky wet cell under the bench, including several partially suitable ac units with and without regulation.

The main trouble is that the designs available for ac powered supplied are usually for one output voltage only. The few that have regulated output over a wide voltage range are: (1) hopelessly complicated; (2) very expensive; (3) have poor regulation characteristics; and (4) protective current limiting circuitry is not included.

After absorbing an article by W6GXN (*73* December 1966) and information published by Editors & Engineers Ltd, (*The Transistor Radio Handbook*) and several cups of coffee, here is my answer.

Before you read further though, please understand that this is not a blow-by-blow construction article. It is a basic circuit idea which may be further developed by evaluation of the contents of your junkbox.

The circuit put forward by W6GXN is that of Fig. 1. This is fine for a voltage which needs to be variable over a small range. For larger voltage excursions, such as those required when working up an experimental circuit, several problems arise. The main trouble is that D1 needs to be at least 1/2 the rectifier output voltage to provide adequate regulation at the lower settings of R2. This high D1 potential then limits the minimum voltage to approximately 1/2 the maximum output. Also, no current limiting is provided for those accidental short circuits.

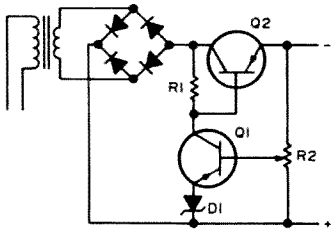

Figure 1.

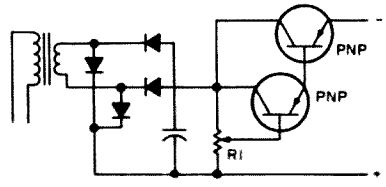

Figure 2.

Other sources propose circuitry similar to Fig. 2. This provides a full range variable output but defeats part of the idea as there is no feedback loop to provide adequate regulation under varying load currents.

Remembering Fig. 2 but going back to Fig. 1, it was deduced that if D1 rather than R2 were the variable element, a part of the difficulties would be overcome. Figure 3 was hastily thrown together to prove this point.

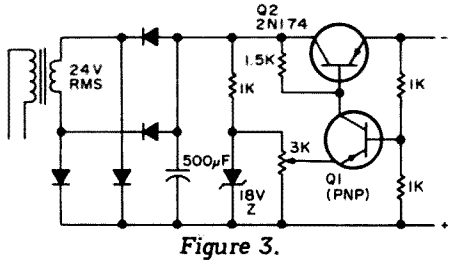

Figure 3.

As anticipated, the voltage was variable from 1.1 to 29V. For small variations in current the stability was fair but larger load changes caused a loss of regulation. At the minimum voltage settings Q1 must drop the full 30V supply across the 1.5K in its collector circuit. This current (20 mA) is put across a part of the 3K pot and thus the regulation of the emitter supply is degraded (so is the future usefulness of the pot)!

After several more cups of coffee, a few unsuccessful circuits, and a couple cooked transistors, the connections in Fig. 4 proved promising.

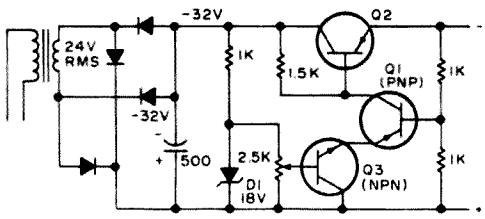

Figure 4.

Emitter follower Q3 provides a very stable regulated reference voltage for the emitter of Q1. This voltage is variable over 0.8 to 18 volts. Since the base of Q1 samples 1/2 the output of Q2's emitter, this lets us vary the output from 1.4V to the full output of the rectifier.

Extensive tests of the voltage change under load were not made but spot checks indicate adequate regulation at any set output.

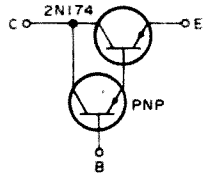

Figure 5.

Of course percent regulation is a function of the gain of your particular transistors. Another PNP might be connected to the 2N174 to make a darlington pair (Fig. 5) but this was not tried here. This would allow you to increase the resistance of the 1.5K and thus lower the current thru Q1 and Q3. It might be worthwhile if you feel a need for better regulation.

So much for the variable voltage part of the supply. Now for a simple and reliable current limiter design.

Here several circuits were tried which would provide a current sampling network and cause a voltage droop in the emitters of Q1 and Q3. All were discarded because they, affected regulation, did not limit current, or blew transistors, and/or a combination of all three!

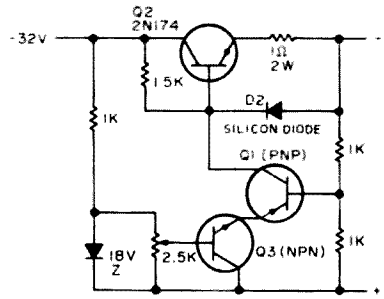

Figure 6.

Figure 6 grew out of desperation and as usual this simplest way proved to be the best.

Diode D2 is normally reverse biased by the emitter-base voltage of the 2N174. At a current of approximately 420 mA the drop across the 1Ω resistor is adequate to overcome this bias. At that point D2 conducts and limits the current flow to this level. Make that a 1Ω rheostat and you have variable current limiting.

Now as a final filter, add a 100 MFD across the output and you have 1.4 to 32V at up to 420 mA.

Other voltages could be built up with a change in transformers. Just keep the zenner at about 1/2 the total output volts.

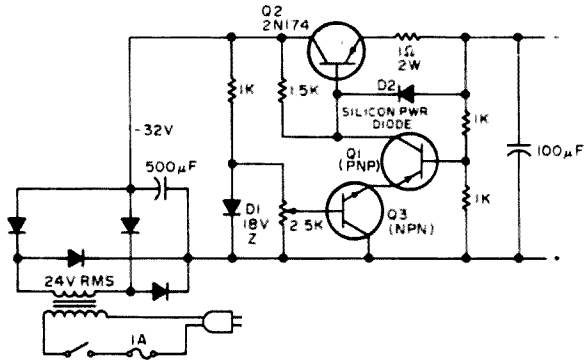

Figure 7.

Higher current could be achieved with parallel transistors for the series regulator. Here the darlington pair idea mentioned earlier might be of use. Remember to adjust the value of the current limiting resistor accordingly. The complete schematic of my supply is shown in Fig. 7, but as I stated earlier, this is a junkbox project so your's may develop significant differences.

DISCLAIMER: I cannot offer a bibliography of references for the circuitry presented here as most of it evolved from memories of various commercial, industrial, and amateur equipment I've encountered over the past 10 years. My only claim to originality is the particular component values used for my supply.

IC Six Meter Receiver

This is about a six meter receiver that uses a high-gain IC (integrated circuit) in the rf stage, another for the i-f, and a third for the af. If that sounds like a lot of high-gain-ICs, you're right! As I write this (happens to be 3 am), K1YNU is talking. He is in Rhode Island, a mere 105 miles airline away from here in Peterborough, N.H. For some reason – not completely figured out as yet – this receiver is extremely sensitive and you can hear everyone that comes on the band. Part of this may be the relatively broadband i-f stage. As a battery-operated complete, single conversion superhet, easy to homebrew, it certainly warrants attention, as you will see. Here we will describe the ICs used, the breadboard operation, and results. Later we will go into getting maximum selectivity with the 1.65 MHz i-f section, avc circuitry, gang tuning, packaging in miniboxes, narrowband i-f, and a companion transmitter to go with it, with several watts output.

As you can see from Fig. 1, this is a single conversion, tunable superhet. The Motorola IC HEP 590 has over 30 dB gain and is probably the main item contributing to the high sensitivity. Not having (so far) a mixer and oscillator IC, the universal (my name for them) HEP 55 transistors were used here. Another 30 dB in the i-f, with excellent gain control characteristics, is achieved by the second HEP 590.

The demodulation was given an extensive workout because this item has to be just right for DX work. The demodulation is done with a 1N295 diode, connected across a separately tuned circuit on 1.65 MHz. The details are in Fig. 7. The af is quite good, using the Amperex eleven transistor audio IC. Be sure and check the details. The 8Ω loudspeaker is a Lowell which has quite a magnet on it. It is direct-coupled to the 1W af output circuit, and contributes to the good audio obtained.

Figure 2 shows the overall schematic, which is a happy combination of two types of ICs and two discrete transistors. This unit needs gang-tuning and the narrowband i-f to make it into a deluxe receiver, but these are not difficult to add. As a breadboard unit it is extremely interesting to use and generates plenty of thinking about communication ICs and their future amateur use.

Rf Stage

These little Motorola HEP 590 IC units are beginning to show up as really amazing for rf and i-f work. The gain is high, even at 50 MHz, the noise figure is good, the freedom from feedback is as low as they

claim, and fine avc action is provided without distortion or detuning of the input. Figure 3 shows the internal schematic of the three transistors inside the case, which is only 3/8 in. in diameter, and Fig. 4 shows the external components.

I have been using it for some days now in front of my lab receiver while working and no spurious has shown up so far. The manual control on the avc is perfect, although you don't need it just for rf. This manual control uses the avc input line going to Q2, which is pin 5 in Fig. 2, and it is a nice thing to have in reserve when and if you tack on more i-f stages. It will be used later in its regular automatic form. It operates on Q3, leaving Q1, the input stage, in the low noise condition.

The way this is done, referring to Fig. 3, follows. The current of Q1 goes to both Q2 and Q3. With positive avc voltage on the base of Q2 (going in through pin 5) the current flows only through Q2, and Q3 is turned off with the gain of the amplifier then at a minimum. If the avc voltage on Q2 is *less* than that on the base of Q3 by at least 224 mV, all the collector current in Q1 will flow through Q3, which is the condition of maximum ac gain. Due to Q1 being on all the time, input tuning will remain constant, another advantage of the 590.

The combination of Q1 and Q3 acts as a common-emitter common-base pair and as such reduces feedback by two orders of magnitude compared to a single transistor. This of course is one of the biggest advantages of the 590 IC. All things considered, this unit is an excellent rf amplifier and an intriguing example of things to come in integrated circuits.

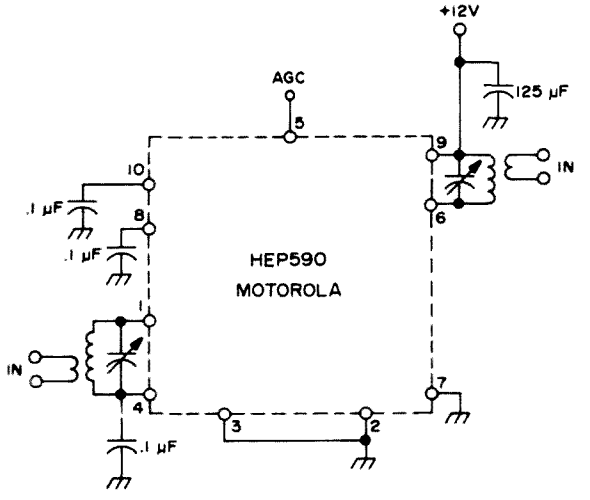

Fig. 4. External schematic for HEP 590.

The Mixer and Oscillator

These are the only discrete transistors in the receiver, and they're only in it because I haven't yet found an IC substitute for them on VHF and UHF.

The mixer circuitry shown in Fig. 5 has a minimum of components because it uses the tuned collector coil of the rf stage for its input. A capacitor over to the oscillator and an i-f output coil complete the deal.

An interesting thing about this mixer is that, while being extremely sensitive, it has not produced a single spurious so far. No birdies have been heard in several days of operation.

The local oscillator is shown in Fig 6 and is more or less standard with me because it is turning out to be very reliable.

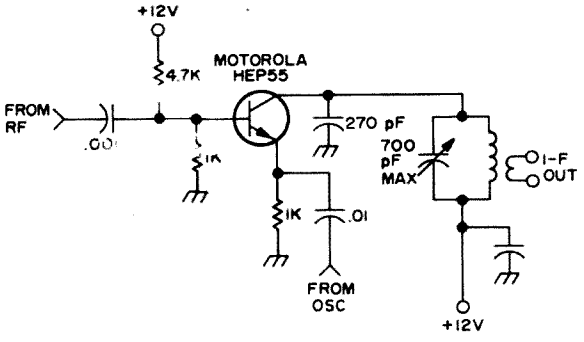

Fig. 5. Mixer schematic.

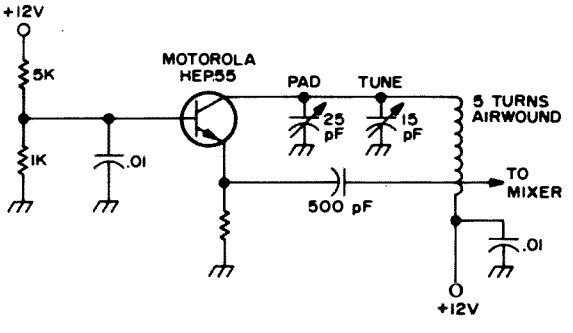
The whole inductance including the feedback portion is tuned so that considerable reserve power is available. Tap one, the oscillator emitter rf connection to L1, can be varied to suit. Right now it is less than one turn from the ground end of L1. The mixer tap is also at the same place at present, and the results are quite remarkable. I'm getting very excited about the possibilities on Two as well. Maybe it will replace the receiver of my sorely-missed Communicator Three which I *never* should have sold.

The IC I-f and Demodulator

From the way these Motorola HEP 590's worked in the rf stage, I got the idea that maybe only one of them would do for the i-f stage. It turns out that there is *more* than enough gain. You can't stay in the room with everything full on! It's really fascinating. I'm listening to Six as I write, and I can hear everyone within at least 100 miles.

The i-f details are clearly shown in Fig. 2. This i-f portion was installed on a separate copper-clad plank in order to check completely just what it could do, and it sure paid off. At 1.65 MHz there is probably more than 30 dB of gain, and so far it has never oscillated even once. Motorola claims that the "Reverse Transfer Admittance" (that old Devil feedback) is very, very, low. Here are Motorola's words, "... is extremely low since in terms of millimicromhos it involves the product of two numbers less than unity, divided by a number greater than one. Hence the fact that it is extremely difficult to measure is understandable." The figure given is less than .001 millimicromhos, therefore it can



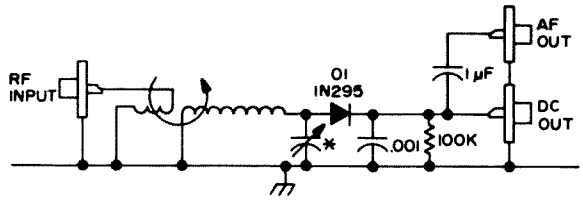


Fig. 6. Tunable local oscillator.

* 1000 pF MAX (3 GANG STANDARD BROADCAST VARIABLE CAPACITOR, ALL THREE SECTIONS TIED IN PARALLEL.

Fig. 7. Diode demodulator, 1.5 to 8 MHz. The coil data is with Fig. 2.

be neglected. So, I neglected it and no oscillation has yet occurred.

The inductors used are detailed in Fig. 2, and will be the subject of considerable experimentation in the near future. The advantages of a single conversion are important, but put a strain on the selectivity question. You need at least 1.65 MHz to avoid excessive image, and selectivity approaching 10 kHz (if you can get it) at 1.65 MHz is not easy. However, as you will see by Fig. 2, we have four tuned circuits, the mixer collector, two in the i-f plank, and the fourth in the tuned diode unit. Cup-cores from Miller 10-C tube-type i-f transformers are used for three of these, and the fourth is an air-wound job, 23 turns per inch, with about 750 pF across it. This is giving separation of some 80 to 90% of the stations on the band, and will do for the moment. There is a question of price also. Coils wound with Litz wire, that is, a number of strands of enamel wire wound into one cable such as "5/41" which is 5 strands of No. 41 enamel each, have a better Q than those wound with a single wire, but the price is a lot higher.

The i-f described here works like a charm except for a slight overlap on close stations. Another HEP 590 on 135 kHz will of course give you selectivity down to 3 or 4 kHz.

Demodulation

As you may have noticed, I like Admirable Modulation. On VHF and UHF, and up into amateur microwaves there is plenty to do, with amateur Space Stations coming up and all, without going into a bunch of up-converters and then a lot of linear amplifiers to get SSB power on those

frequencies. These present special difficulties when using solid state, to end up with modulation which does not even enable you to recognize your best friend's voice. Just my opinion, so I'm stuck with it for now. Anyway, AM demodulation circuits can sometimes give you trouble, especially when combined with avc, so let us take a look.

The circuit shown in Fig. 7 is an old-timer, but very valuable for certain types of work such as i-f amplifiers. It has its own "plank" and dial and is calibrated from about 1 MHz up to near 8. It is an excellent reference point for audio quality to start with, allowing a check into the BC band when needed. This is not to say that all those high-end BC stations are Hi-Fi! It adds another tuned circuit to the i-f for increased selectivity, allows you to check for yourself the desirable values of C2, C3, and R1, and has a dc output for metering small improvements in gain. It will be built into the i-f strip later, when the exact inductors, capacitors and resistors are determined.

The Audio IC

Figure 8 shows the internal circuit of the Amperex TAA-300 audio integrated circuit. The external circuitry is clearly shown in Fig. 2. This tiny 3/8 in. diameter can contains no less than eleven transistors and five diodes, and has been engineered to

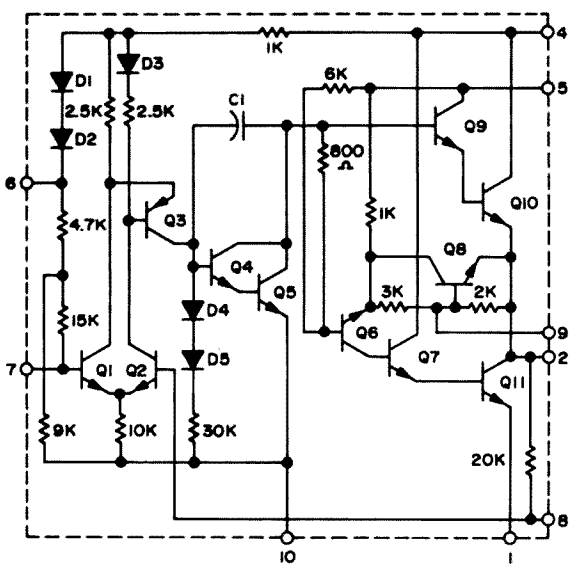

Fig. 8. Internal circuit of the Amperex TAA-300 audio IC one watt amplifier.

put out a clean watt of audio energy from 20 Hz to 25 kHz, which it does, I can assure you. It has negative feedback which can be made variable by the use of the pot attached to pin 8. Checking the internal circuit shown in Fig. 8 you can see that pin 8 is the base of Q2 and the 25 mF capacitor bypass would shunt the feedback to ground if the pot were not in series with it. With this pot at zero ohms the amplifier gain is very high, and with it at maximum there is a lot of feedback, which cuts the gain down but increases the quality of the audio. For a fixed value, Amperex recommends 47Ω.

A high frequency cutoff control is used at the input because for communications work you do not need 25 kHz response. You can also cut down on the lows because for communications you don't need 20 Hz either! Reduce the value of the input capacitor on pin 7.

Shunt pin 4, the dc input, with at least 150 mF, and run a .05 to ground from pin 2 to remove high frequency instability from the lower of the Darlington pair, Q11. Keep the input and output leads apart, preferably using shielding on the input. Use an 8Ω speaker for the best match to the transformerless output circuit. This unit is actually as claimed, a "Miniature Hi-Fi Amplifier," if you're interested in such. I am very impressed with it.

Running this receiver "as is" without the narrowband i-f following, I can repeat that some 80% of the stations will be QRM-free. Also, this figure may be increased later when I really get into the selectivity bit on 1.65 MHz. Further, rotating the beam would help cut down QRM.

If you take the time to gang the three tuning capacitors, package the whole set in one (or more) boxes, add a narrowband i-f strip, and make up a good solid state transmitter to go with it, you will have an excellent portable, mobile, and emergency rig.

If you use it "as is" you will be surprised at what you can hear on Six. It also can give you an instant check on band openings if you leave it hooked up with its own little battery. ...K1CLL

A Tracking FM-AM Demodulator using an IC

This is the second of two articles, on the use of the phase-lock loop as an FM/AM demodulator.

The circuit to be described uses the Signetics Corp. NE561B IC and is based on Signetics' application notes. Besides providing demodulation of the FM component of a signal and perfect afc tracking of that signal, provision is also made for the synchronous demodulation of the AM component of the signal.

A block diagram of the NE561B is shown in Fig. 1; the portion enclosed in the dotted outline is in addition to the basic phase-lock loop already described. The AM input is taken before any limiter in the main receiver and its phase is shifted 90° with respect to the FM/rf input. This is necessary to have the correct phase relationship between the AM signal and the VCO input to the multiplier.

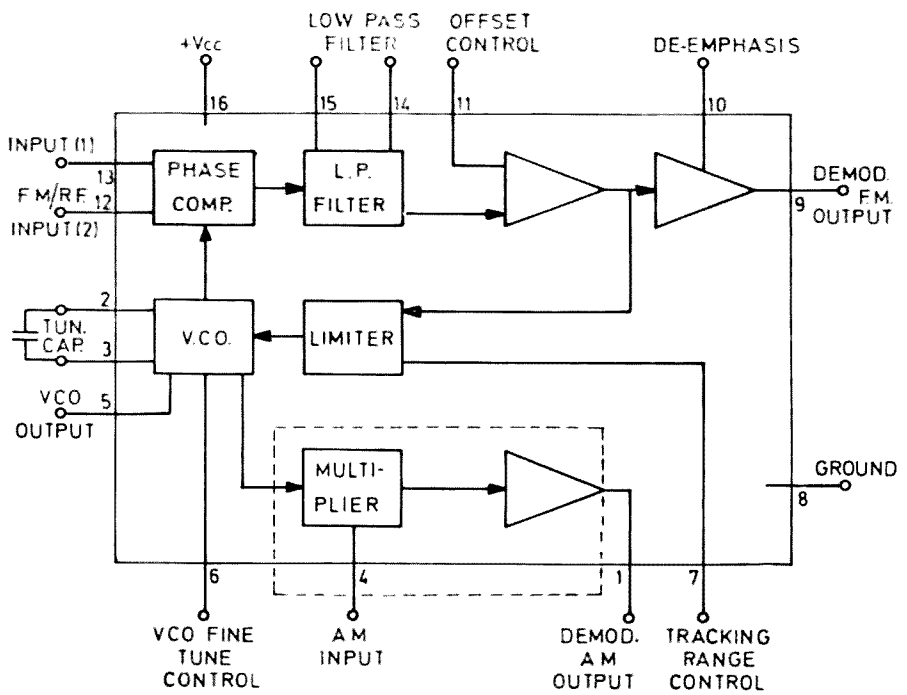

Fig. 1. Block diagram of NE561B.

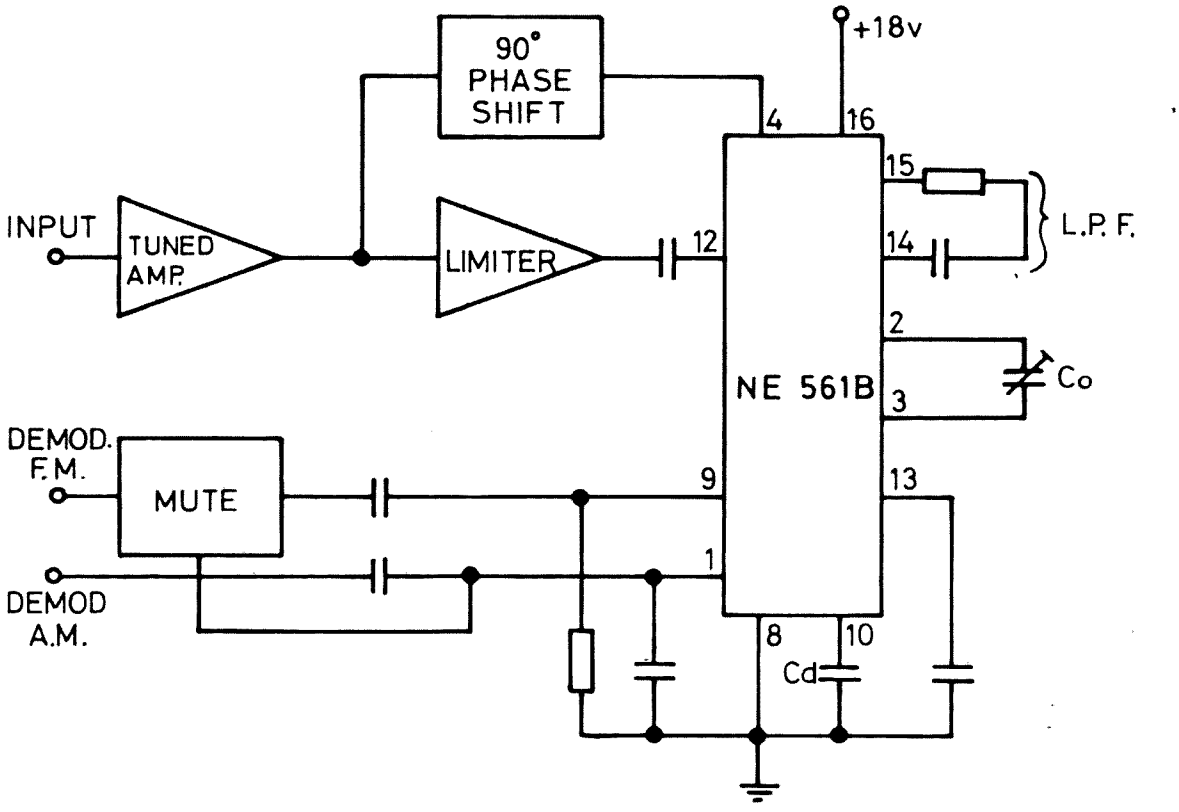

Fig. 2. Basic demodulator.

Shown in Fig. 2 is the basic demodulator. With reference to Fig. 1 we have the limited FM/rf input applied between pins 12 and 13, phase shifted AM input applied at pin 4, the VCO frequency determining capacitor (Co) connected between pins 2 and 3, the external components of the low pass filter between pins 14 and 15, and the FM de-emphasis capacitor (Cd) connected between pin 10 and earth. The muting function is accomplished by use of the output of the AM detector to open an audio gate in the presence of signal input.

The circuit diagram for the complete demodulator is shown in Fig. 3. Circuit functions can be most readily seen with

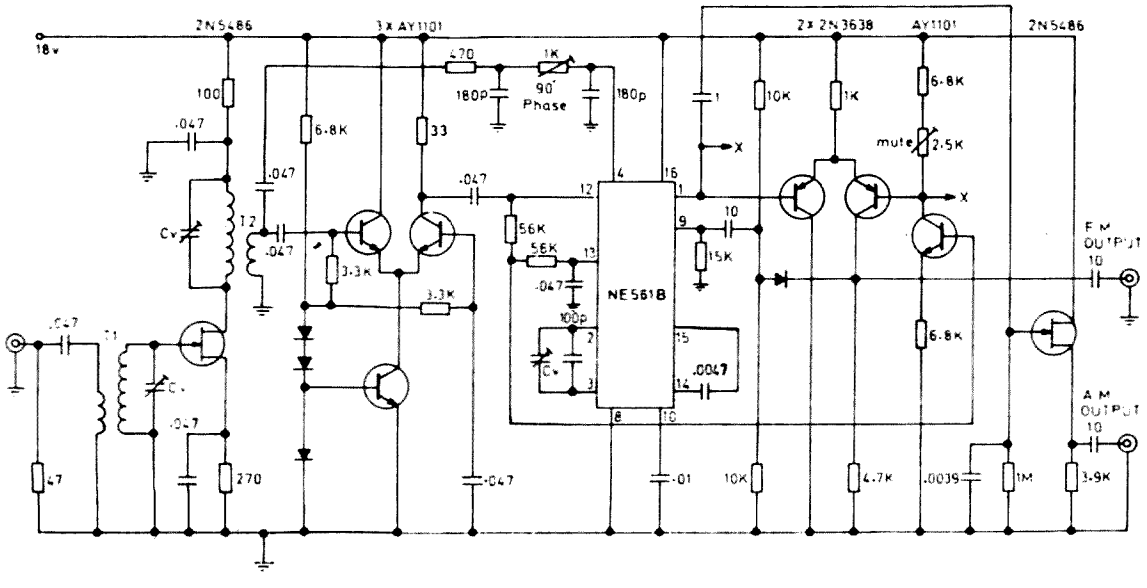

Fig. 3. Phase-lock demodulator.

reference to Fig. 2. The design centre frequency is 2 MHz, but the NE561B will function from less than 1 Hz to more than 15 MHz. Input signal is amplified by the 2N5486 JFET which is wired as a simple tuned amplifier at the required i-f. Three AY1101 transistors are used in the limiter, while the 90° phase shift is provided by an adjustable RC phase shift network.

Muting of the FM output is performed by the use of a suitably biased diode as a series gate. When no signal is present, the diode is reverse biased by the 2 x 2N3638 emitter coupled pair and when signal is applied the output from the synchronous AM detector causes the emitter coupled pair to forward bias the diode and allow signal through to the FM output.

The AY1101 transistor is used to set bias levels relative to those of the IC. AM output is taken from pin 1 via a JFET source follower; an MPF102 would be suitable for this function. The AM detector can also be used to give an indication of signal strength. A suitable circuit is shown in Fig. 4.

If operation at some i-f other than 2 MHz is desired, (e.g. 455 kHz) it would be necessary to change the resonant circuit in the JFET amplifier, change the VCO timing capacitor Co (e.g. 600-800 pF) and the 90° phase shift network (e.g. 2.2K, 5K pot., 2 x

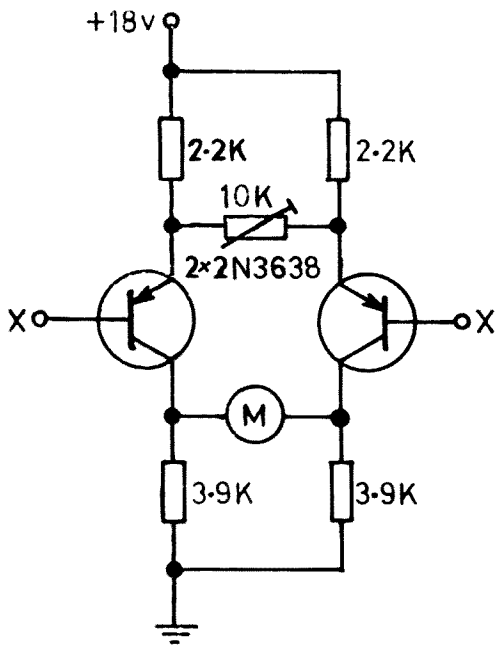

Fig. 4. Signal level indicator.

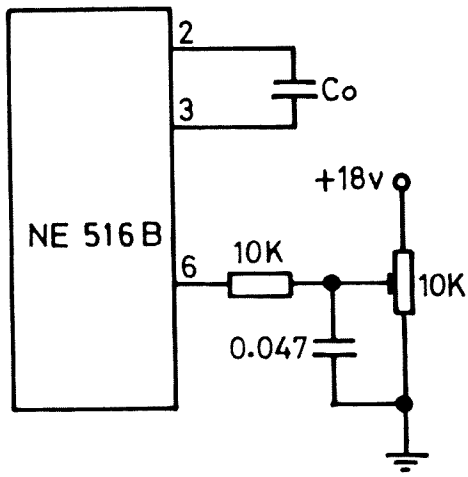

Fig. 5. Alternative VCO fine tuning.

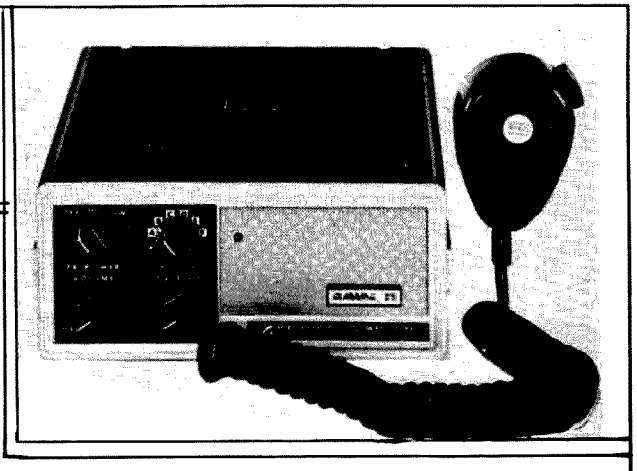
150 pF). If a frequency less than 500 kHz is required, consideration could be given to the NE565 which will function as an FM/PM detector but does not provide for AM detection and consequently muting.

An alternate method of fine tuning the VCO is shown in Fig. 5 in which current is injected into pin 6 of the IC. A change of +12% is possible for an input current of 1 mA. This method of fine tuning will also affect the tracking range of the demodulator.

This completes the description of the phase-lock demodulator.



Such a unit as has been described in this article is in use in a satellite tracking receiver used for monitoring navigational and weather satellites. The principal use of the phase-lock type of detector for this application is the automatic tracking of the Doppler shift of the signal which is as much as ±4 kHz at the frequencies used.

When the proposed amateur satellite with the active repeater on 432 MHz becomes operational, Doppler shift of at least ±10 kHz will be experienced on the received signals from the satellite. It will therefore be necessary for stations receiving the signals to provide some form of tracking of the signal frequency. If such a tracking filter/demodulator as the one described in this article is used, the receiver bandwidth must be the signal bandwidth plus 20 kHz to allow for Doppler shift.

W7DXX/1 (continued from page 128)

out of band it's rather difficult for 6 stations to sneak across 10 kHz. The other evening I was tuning across the high end of 20 SSB looking for a clear spot. My sked called for the first clear spot below 14.350. As I tuned between 350 and 340 I was amazed at the lack of activity. "Maybe this is not the QRM capitol of the world after all," I thought. So, I picked a spot just inside 14.350 and gave my friend a call. He came right back. As it happens quite often, after we had been talking about 5 minutes someone broke in and joined us, then someone else, and then still another until there were six of us having a nice round-table QSO. I pulled out the old trusty 10 minute timer so that identification went like clockwork. (No pun intended.) After a half hour or so, it suddenly hit me. I had been looking at the wrong VFO dial. I was, we were, all six of us were on 14.360. I didn't really know what to do or say. My first reaction was to say, "Well fellas, I'd better get back upstairs and get some work done." They could then worry about themselves. However, since I had started the whole thing it didn't seem quite right. Then too, after more than a half hour of operation at 14.360 I was sure there was a monitoring station using up a heck of a lot of recording tape on us and having a blast writing out all those citations. It occurred to me that perhaps the best way out was to "fess up" to the other guys. After mentioning the fact that we might be "out of the band just a little" we all spent another 5 minutes or so verbally trying to figure out what to do. We came up with several good possibilities. Like using our MARS calls, or just pulling our wall plugs. We finally decided that the best thing to do was to announce the fact that we realized we were in error, identify, apologize and get back into the band. This is what we did. It was sort of a one way transmission to all the FCC monitoring stations. I, as an example, said: "This is W7DXX operating portable one from Peterborough, New Hampshire. If there are any monitoring stations listening we realize we are accidentally out of band and will now QSY . . . sorry." After the whole thing was over and we were back in the band I couldn't help but feel extremely foolish. Not only for being the cause, to a degree, of six stations operating out of band, but for not really knowing what to do after finding myself in the situation. As far as I can recall, this is the first time I have ever found myself out of band. I suppose I could blame it on the new and unfamiliar equipment I was using. However, no citations have been received by any of the five participants so maybe we did the best thing after all. What do you do when you find yourself out of the band . . . Got an answer?

ACTIVE FILTER DESIGN AND USE PART III

In Parts I and II basic LC filters were developed into active filters utilizing transistor amplifier stages and RC circuits. In this process, we showed that the bulky inductor, or indeed any inductor, was not only unnecessary, but in most cases a hindrance to design and stability. The use of transistor amplifier stages with network selectivity determined by feedback components presents a flexible mechanism adaptable to any filter requirement. One of the main advantages of the active filter is the replacement of high insertion losses normally associated with LC filters with little or no insertion loss and, in many cases, overall gain. At the lower frequencies, inductors become quite lossy and good circuit Q's become more difficult to obtain. Substituting gain stages for these unwieldy components allows the designer to set a value of Q optimum to the desired response.

In spite of the many advantages of transistorized active filters over the passive LC types, there are also some disadvantages. Due to the problems of impedance matching input and output of transistor stages, utilizing a minimum number of components requires that the transistors be incorporated in an emitter follower configuration, thus limiting gain to unity. Naturally, if the number of components, or expense, was not important, design would be somewhat simpler and the resulting response somewhat better. Recent advancements in integrated circuit manufacturing processes have managed to bring the average cost and availability of these components within the reach of the amateur and provide a means of improving the performance of the active

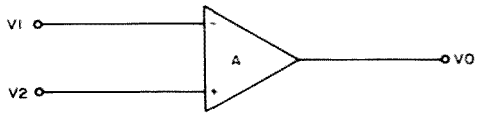

Fig. 1. Operational amplifier.

filter while retaining the low cost of the simple transistor version.

One of the most versatile of the integrated circuit family is the operational amplifier. The ideal operational amplifier is basically a two-input, infinite gain, voltage-controlled voltage source. Figure 1 shows the symbolic representation of the operational amplifier. The output voltage, Vo will always be of the same polarity as the voltage at one of the input terminals and of opposite polarity to that of the other input terminal. Output level is a function of input level and gain of the amplifier:

$$Vo = A(V2 - V1)$$

In considering the use of operational amplifiers as active components in a filter network, there are many advantages to be noted. An increase of reliability is possible due to the closer matching of active and passive components and temperature stability of these components mounted on a single substrate. An additional advantage is evident in reduction of size, weight, power consumption, and cost of a similar passive network.

Unfortunately, the practical operational amplifier is a non-ideal device, the voltage gain of which is highest at dc, decreasing as frequency increases. Naturally, it has a finite input and output impedance and a stability factor which may require negative feedback to preclude oscillation. Stability is normally no problem when utilizing the operational amplifier as an active filter element since the

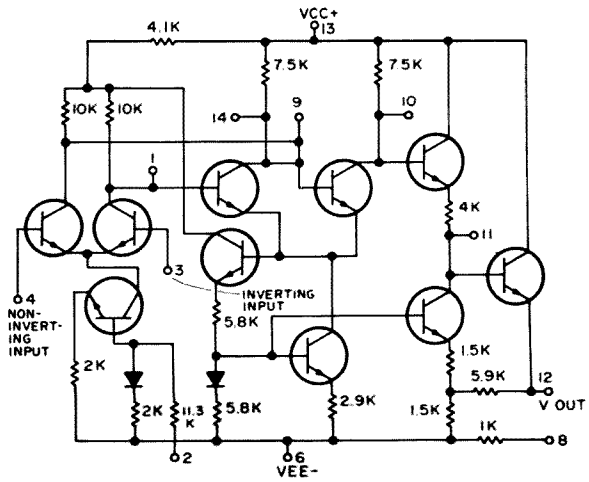

Fig. 2. RCA CA3030 operational amplifier.

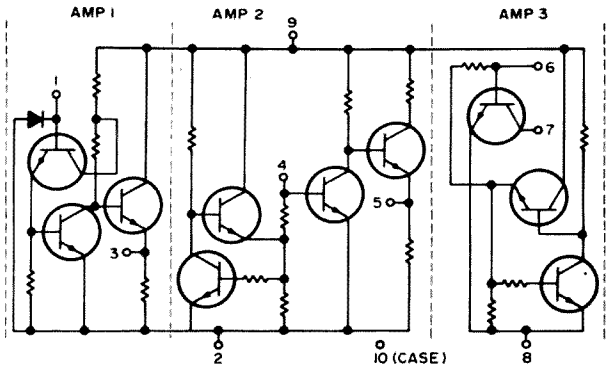

Fig. 3. RCA CA3035 linear amplifier.

outboard frequency compensating components will also serve to make the circuit independent of unstable response, temperature variations, and power supply fluctuations. Referring to Fig. 1, the input labelled V1 is known as the inverting input and any signal inserted here will be 180° out of phase at the output. On the other hand, V2 is a non-inverting input and will not produce a phase shift at the output. The notation "A" indicates open-loop gain of the amplifier without external components. Although either input can be utilized as the signal source, the inverting terminal has the advantage of allowing more gain and attenuation of unwanted frequencies. This is especially true in the low pass filter configuration where the feedback capacitor originates at a low impedance output point.

The input stage of the operational amplifier consists of two transistors connected to form a differential amplifier. The RCA CA3030 operational amplifier in Fig. 2, shows the two input transistors connected back-to-back. This configuration provides a high input impedance and allows the offset (signal level above dc base) to be adjusted via the "no-signal" input terminal. The input

differential amplifier is followed by voltage gain stages which raise the signal to a high level. Various terminals are brought out of these voltage gain stages to allow frequency compensation. The final stage of the amplifier is a low impedance output in the form of a push-pull emitter follower which provides freedom from loading which might affect the desired frequency response. Since the operational amplifier is a bipolar device, it will amplify both positive and negative voltage swings. Although some integrated circuits may be used with single polarity power supplies, by additional circuit modifications, it is wise to use positive and negative supplies with a common ground, as recommended by the manufacturer.

In utilizing integrated circuits for active filter design, there are a number of new problems which are not so apparent in transistorized filters. First of all, with integrated circuits we have a number of transistor stages, with their associated components in very close proximity to each other on the same physical base. Consequently, freedom from internal feedback becomes an important factor. Similarly, external frequency determining components must have short leads and, in some cases, be physically oriented to prohibit stray pick-up. Secondly, circuit stability is dependent on gain and loading among other parameters. As an example, failure to match the low output impedance of the integrated circuit will tend to change the frequency response of the filter, increase current drain, and decrease applied voltage. Using the integrated circuit in the inverting mode to obtain additional gain requires careful design of input signal range and supply voltages to preclude the possibility of oscillation. With increased gain, it is more difficult to design a filter with a sharp 3 dB cutoff point. In addition, where we could easily expect a passband flat to ±1 dB limits when working with transistor

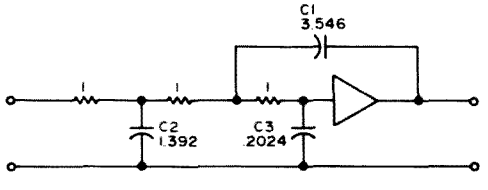

Fig. 5. Normalized low pass.

filters, we now must employ extra sections to create a flat response.

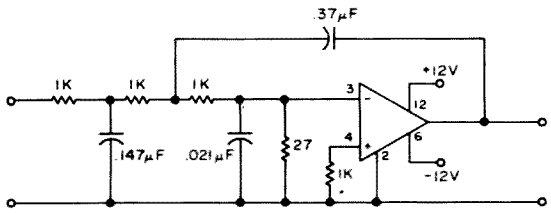
In order to estimate the passive component values for active filters, we use a network normalized for a frequency cutoff of 1 radian per second. The network shown in Fig. 4, gives the normalized component values for a three-pole filter to produce a Butterworth response. Recomputing the capacitor values, by frequency scaling for a 3 dB cutoff at 1500 Hz gives:

$$C_1 = \frac{3.546}{2\pi(1500)} = 370\ \mu F$$

$$C_2 = \frac{1.392}{2\pi(1500)} = 147\ \mu F$$

$$C_3 = \frac{.2024}{2\pi(1500)} = 21\ \mu F$$

More practical values for the capacitors are obtained by impedance scaling. In this operation, the normalized resistance values are multiplied by the desired filter impedance value while the capacitors are divided by the same figure. Utilizing a new figure of 1 KΩ provides the values shown in the network of Fig. 5. The non-inverting input of the integrated circuit should be terminated with a value of resistance equal to the impedance seen by the inverting input transistors of the operational amplifier, the value of this resistance may be much lower than the input impedance, and can best be found by substitution after the designed value frequency selective components are in place. To increase stability of the network, the inverting input is biased with a resistance determined by the level of the input signal and the gain of the operational amplifier. The RCA CA3030 operational amplifier is



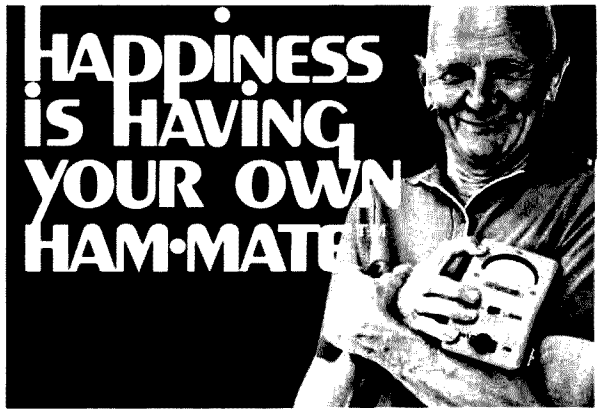


Fig. 6. 3-pole low pass filter.

The New HAM-MATE™ Directional RF Wattmeter is a direct descendant of the famous model 43 THRULINE® – the professional standard of the industry. Designed specifically for the serious radio amateur, three models currently available measure forward and reflected power in the following ranges:

4350: 2000/200W, 1.8-30MHz (160 meters to 10 meters)
4351: 1000/200W, 1.8-30MHz (160 meters to 10 meters)
4352: 400/40W, 50-150MHz (6 meters, 2 meters)

All have an Insertion VSWR below 1.1 in 50-52 ohm lines, a minimum of 20dB Directivity, 8% Accuracy, SO-239 female UHF connectors and carry the 12 months guarantee of all Bird instruments.

used in this low pass network as an example of a low-cost integrated circuit for active filter work. The response of this network is shown in Fig. 7a. The tolerance of the components used in this circuit was 10%. Closer tolerance components, or trial and error replacement, will bring the cutoff frequency down to the desired 1500 Hz point. The circuit exhibits gain of 7 dB indicating that higher values of network resistors might be used if it is desired to obtain more common electrolytic capacitor values. The attenuation curve is not as steep as it might be. This is mainly a problem of Q and lack of component isolation in the integrated circuit.

Normally, we would expect a noticeable increase in attenuation slope when adding filter sections. Figure 8 shows the normalized values for a two-pole filter with Butterworth response. Utilizing the same cutoff frequency, computations for the component values appear as follows:

$$C_1 = \frac{1.414}{2\pi(1500)}$$
$$= 150\ \mu F$$

$$C_2 = \frac{.707}{2\pi(1500)}$$
$$= 75\ \mu F$$

With 1 KΩ resistors:

$$C_1 = \frac{150}{1000}$$
$$= 150\ \mu F$$

$$C_2 = \frac{75}{1000}$$
$$= .075\ \mu F$$

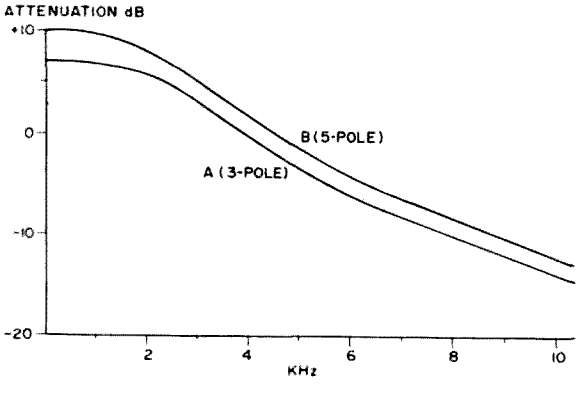

Fig. 7. CA3030 low pass response.

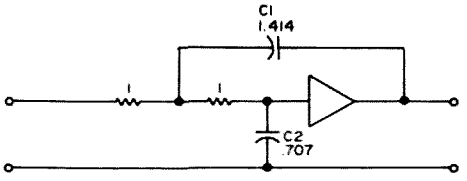

Fig. 8. Normalized 2-pole low pass.

The new two-pole configuration is shown in Fig. 9. With this section added to the previous three-pole network, the five-pole filter provides us with 10 dB gain, but, as can be seen in Fig. 7b, no additional attenuation. Thus it is not possible to vary the response curve by adding additional poles without recomputing the pole values for the entire filter. In other words, to change a three-pole network to a five-pole configuration, calculations from normalized values for a five-pole design must be made rather than adding a two-pole section. An exception to this rule exists when an RC network is added to the output to flatten the response; however, these components are not normally considered an active pole of the filter.

Although the versatility of operational amplifiers is hard to match, integrated circuit linear amplifiers are easier to adapt to filter design. The RCA CA3035 integrated circuit linear amplifier, shown in Fig. 3, is an economical, high-gain, wide-band amplifier which can be operated from a single power supply. Three separate amplifiers are housed in this TO-5 case, and they may be operated individually or cascaded for a voltage gain approaching 129 dB. Power supply voltages may vary as much as 5 to 18 volts, and each amplifier is internally temperature compensated in the range -55° to +125°

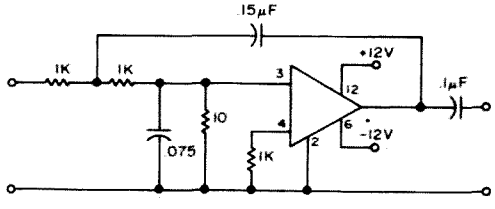

Fig. 9. 2-pole low pass filter.

Amplifier number one offers high input impedance (50 KΩ), low output impedance (270Ω), low noise, and a response flat within 3 dB from dc to 500 kHz. A diode protects the amplifier from possible damage by overloading signals.

Amplifier number two has an input impedance of 2000Ω and an output resistance dependent upon the output load resistor. This amplifier may be externally powered by a separate power supply through pin 7.

Design of a low pass filter with the RCA CA3035 IC linear amplifier is shown in Fig. 4. Resistor R1 provides a bias for amplifier number one. The second and third amplifiers are not used in this circuit. Capacitor C1 couples the signal to the active network while C4 provides output coupling. R2, C2, and R3, C3 make up the two poles of the low pass filter. The frequency response curve for this active filter is shown in Fig. 11a. Frequencies below the 3 dB rolloff are flat within ±1 dB, the attenuation curve is smooth and easily varied by changing the values of the components making up the two poles.

In many cases, a sharper rate of attenuation is desirable than that shown in curve A of Fig. 11. With a few additional components and making use of amplifier number two of the CA 3035 integrated circuit linear amplifier, the slope is easily steepened. Referring to Fig. 10, we now have a three-pole low pass active filter which lends itself well to experimental design on the workbench. The output coupling capacitor, C4 of Fig. 4, has been replaced by a 0.22 μF capacitor which, besides coupling the output

of amplifier number one to the input of the second amplifier, also acts in conjunction with C5 and R4 as an impedance matching component. This procedure is necessary to preclude distortion and loss otherwise encountered when the output impedance is much less than the following input impedance. These components must be selected to assure faithful coupling of the signal over the entire frequency range of interest. Resistor R5 functions as part of the third filter pole in conjunction with feedback capacitors C6 and C7. Capacitor C7 has a great affect on the attenuation slope and may be varied to obtain the exact degree of slope desired. Resistor R6 also helps to match the output/input impedance of the two amplifiers and compensates for the impedance change caused by the feedback network. Curve B in Fig. 11 shows the effective increase in slope attenuation by addition of the third pole and amplifier number two. Note that the three-pole filter still exhibits a nominal gain of 5 dB. The circuit was not designed with obtaining a signal gain in mind, although the CA3035 is capable of a much greater increase in signal level. We would normally be satisfied with a

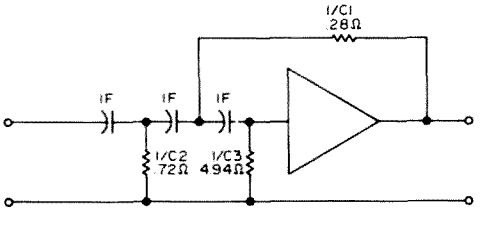

Fig. 12. Normalized high pass filter.

signal gain of unity for a filter in order to preclude possible problems with extraneous coupling and amplifier oscillation.

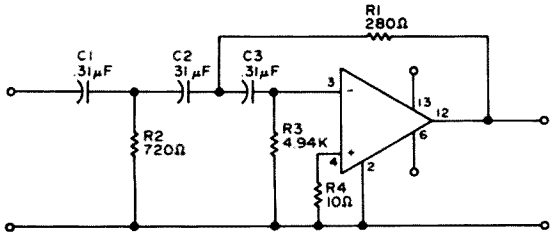
Figure 12 shows normalized values for a three-pole high pass filter. The values are obtained by finding the reciprocals of the normalized low pass configuration shown in Fig. 5. To achieve frequency scaling, all capacitor values are divided by $2\pi FC$. For a cutoff frequency of 500 Hz:

$$C_{1,2,3} = \frac{1}{2(3.14)500}$$
$$= 310\,\mu F$$

Impedance scaling is then obtained by multiplying each resistor value and dividing each capacitor value by a constant chosen for convenience in component selection. Using 1000 as an impedance constant, the circuit values of Fig. 13 are obtained.

From the response curve of Fig. 14a it can be seen that the active high pass filter configuration of Fig. 13 exhibits 7 dB of loss. Most of this loss could be regained by utilizing a larger value constant when carrying out the impedance scaling procedure. Utilizing the closest common value when constructing the ideal circuit of Fig. 13 accounts for the -3 dB cutoff point being about 500 Hz off of the design specification. Overall response and attenuation slope of the high pass filter is good.

The RCA CA3035 integrated circuit linear amplifier does not lend itself as well to high pass filter design as it does to low pass design. This is due, first of all, to the biasing requirements. Base bias is obtained from the B+ line at pin 3, which is the output terminal for amplifier number one. Utilizing the bias resistor in the normal fashion tends to upset the feedback network, thus altering



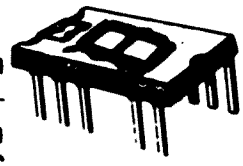


Fig. 13. RCA CA3030 high pass filter.

VHF ENGINEERING

1017 Chenango Street Binghamton, New York 13901

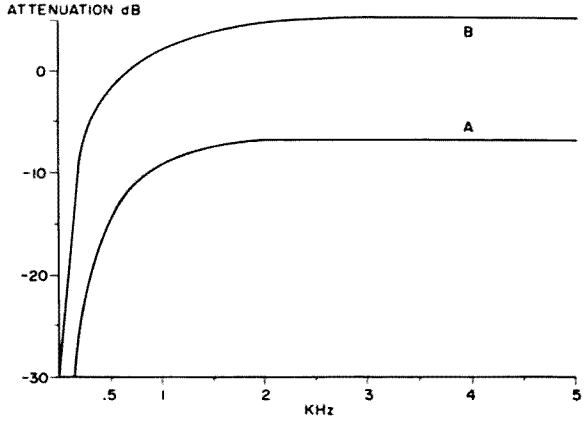

Fig. 14. High pass filter response.

the response. Placing the 5.1 KΩ resistor of the filter network from terminal number one to ground, and not adding the normal 330 KΩ bias resistor, will not permit satisfactory operation due to the diode across the input of the integrated circuit which sets the base at a certain level above ground at all times. Therefore, bias must come from the B+ line and be of a value to preclude clipping of the incoming signal by the diode incorporated into the first stage of amplifier number one.

One method of surmounting the above problems is shown in Fig. 15. For comparison, the same number and value of components has been used as in the circuit of Fig. 13. All filter network resistors have been removed from their normal shunting positions to form parallel circuits where they will not interfere with biasing. Capacitor C1 has been moved to the feedback branch where it functions as a dc blocking capacitor as well as a filter element. The response for this active high pass filter is shown in Fig. 14b. Due to the different design of this circuit, some of the component values should be changed in order to flatten the top

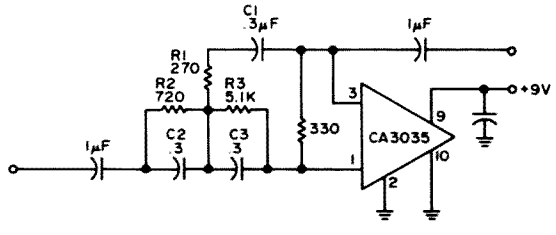

Fig. 15. 3-pole high pass filter with linear IC.

of the curve and place the -3 dB cutoff point where desired. Increasing the value of C2 and decreasing the value of C1 will make the curve more symmetrical without affecting the 5 dB gain.

Figure 16 shows a simple bandpass configuration which is capable of providing good response symmetry when utilized in a circuit with enough gain to allow small signal application. Similar to design of twin-T circuits, the component values for the bandpass may be of almost any value as long as the RC ratio is maintained. However, better results are obtained if the value of R_A is no lower than 1 KΩ. Design values may be obtained by the following formulas where BW is bandwidth at -3 dB, G is nominal voltage gain, and F is the center frequency. By way of an example, we will work out a possible design for a bandwidth of 500 Hz, center frequency of 1200 Hz, with a gain of 10 dB. As a matter of convenience, we will use 0.1 μF capacitors. Where:

$$R_A = \frac{1}{2\pi BW\, G\, C}$$

$$= \frac{1}{2(3.14)(500)(10)(.1\text{x}10\text{-}6)}$$

$$= 31.8\Omega$$

$$R_B = \frac{1}{\pi BW\, C}$$

$$= \frac{1}{3.14(500)(.1\text{x}10\text{-}6)}$$

$$= 6.3\Omega$$

$$R_C = \frac{1}{\sqrt{2\pi C \frac{2F}{BW} - BW\, G}}$$

$$= \sqrt{\frac{1}{2(3.14((.1\text{x}10\text{-}6)\ \ \frac{(2(1200)2)}{500} - 500(10)}}$$

$$= 45.2\Omega$$

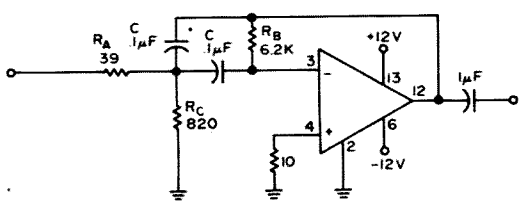

Fig. 16. Active bandpass filter.

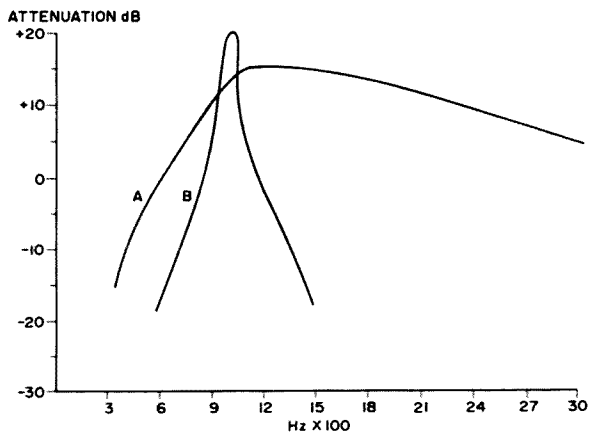

Fig. 17. Bandpass response.

The component values of Fig. 16, derived from these formulas, produce an unsymmetrical waveform as shown in Fig. 17a. Resistor R_C sets the center frequency within ±600 Hz. The change in the value finally needed over the design value indicates an asymmetrical response, as indeed we have. Changing the value of C to .01 μF will increase the value of R_A to 3.3 KΩ and R_B to 62 KΩ. A more symmetrical response will be obtained with these values.

Linear integrated circuit amplifiers are well suited to bandpass use. In Fig. 18, the RCA CA3035 linear amplifier is used in a narrow bandpass version of the twin-T configuration. Component values are determined by allowing R2 = R3 = 2 x R4. Since R2 and R3 are also used as bias resistors, their value should not be less than 150 KΩ. In addition, gain for this circuit is so high that a lower value of R2, R3 will cause a distorted response at the center frequency. The capacitors should be maintained in a ratio

RMV ELECTRONICS

BOX 283
WOOD DALE, ILL. 60191

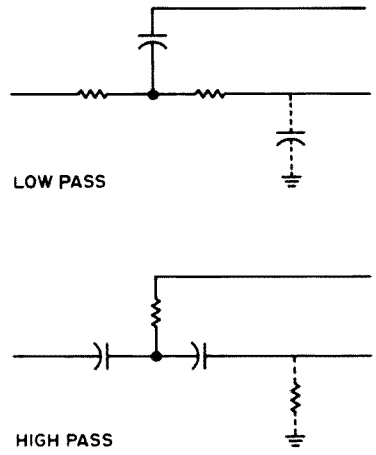

Fig. 19. Basic forms for combining.

where C2 = C3 = C4/2. Center frequency of the narrow bandpass may be found by utilizing the formula:

$$F_{RC} = \frac{1}{2\pi R_2 C_2}$$

This active filter circuit offers a high Q, which can be lowered for greater bandwidth, by decreasing the value of R1. An increase in gain is also obtained when R1's value is lowered. The symmetrical response of the filter, tuned to 1 kHz, is shown in Fig. 17b. An even greater increase in Q may be obtained by increasing the value of R1. This is done at the expense of lower gain.

Depicted in Fig. 19 are the basic RC two-pole high and low pass filter configurations. Using these basic forms in a series configuration will produce a bandpass design while a parallel configuration gives a bandstop response. Increased Q may be obtained by designing individual filters with an increased number of poles, or adapting the design to the specific requirement.

If we parallel the simple configurations of Fig. 19, disregarding components shown by

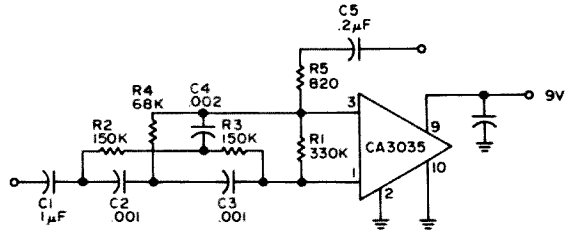

Fig. 20. Narrow bandstop with linear IC.

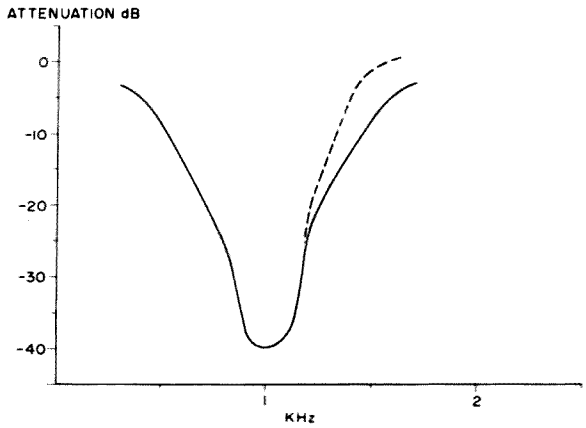

Fig. 21. Bandstop response.

dashed lines, the design takes on the appearance of a twin-T. Thus, the bandpass circuit of Fig. 18 now becomes a bandstop filter. The completed design for the narrow bandstop filter is shown in Fig. 20. Output components R5 and C5 tend to make the response of the filter more symmetrical. The response of the active bandstop filter is shown in Fig. 21. The dashed line indicates the response when a 1 μF capacitor replaces R5 and C5. Using lower values of R2 and R3 in twin-T design will tend to lower the overall Q of the filter.

From the days of the trial and error procedure of winding inductors we have now progressed to the point where a complete filter can be designed and constructed in a space no larger than the size of a quarter, and, in most cases, with better results.

A MODERN VHF FREQUENCY COUNTER

In the last part of our VHF frequency counter series, this month we will cover the actual construction of the unit. Most of the fine details are pretty well covered by the layout drawings, and so we will keep the text itself short. When looking at the drawings, make sure to read the fine print in the notes which may explain quite a few questions.

(If you want to reduce the overall size of the counter, you can cut the board in two with a fine toothed saw, about 4 inches back from the front edge, between the two heavy copper lines running the length of the board. If you stack the rear part of the board upside down above the front part, you can connect the two without too much trouble with short wire jumpers. But make sure to use heavy wire or braid to connect the grounds of the two boards together at the ends of the two boards.)

Construction of the counter is quite straightforward, since almost all components are mounted on the main p.c. board shown in Fig. 19. This board is 7" x 10" in size, with the readouts and the two input circuits along the front (long edge) of the card so they are convenient to the front panel of your cabinet. In order to explain where all the parts go and which part of the main board has which circuit, we've broken up the main board layout into smaller sections, Figs. 20 through 26. Each of these takes one or two of the circuits shown in Figs. 3 through 10 and shows the actual layout of the parts on the board. In each drawing, a small sketch in the corner shows where to find that circuit on the main board, shown in Fig. 19.

Looking at Fig. 19, the front of the board is shown at the top, and the view is at the copper side of the board. A good way to recognize the front edge is by the five 9-pin

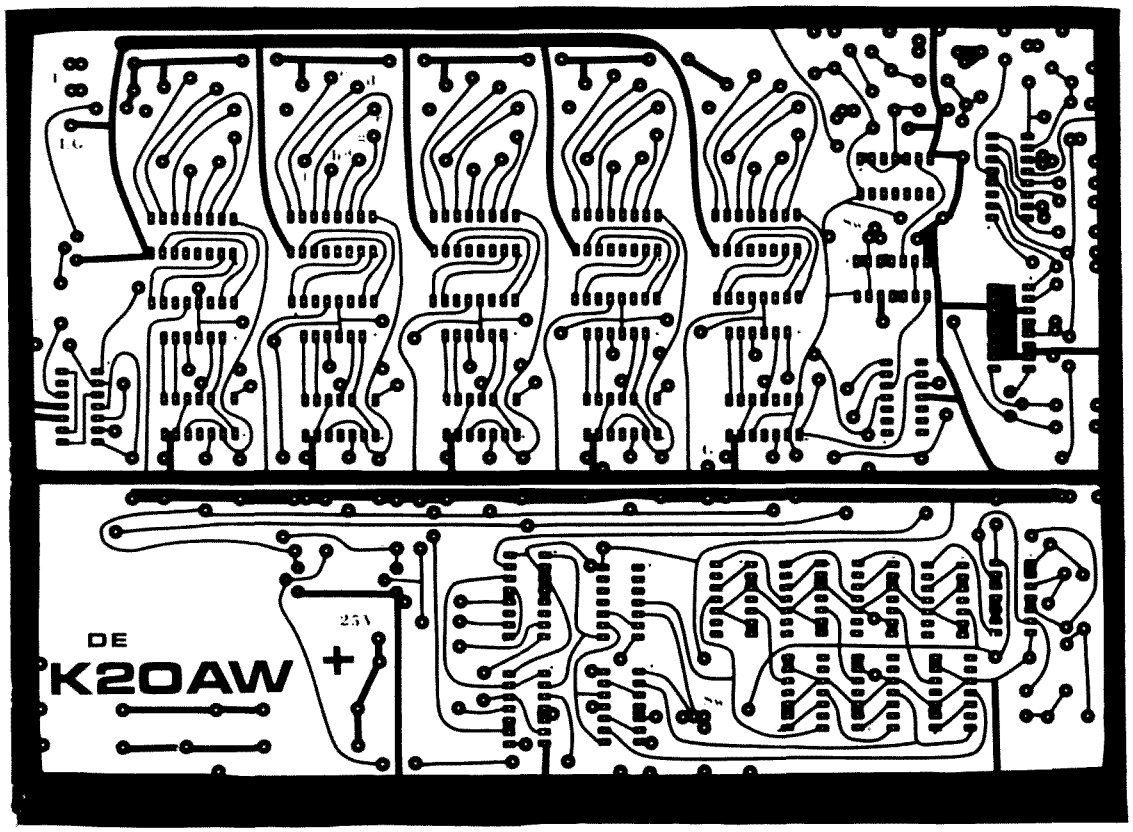

Fig. 19. Printed circuit board layout for main board (copper side, 50% actual size).

Numitron tube sockets along the edge. In each of these figures, we are looking at the copper side of the board. The components actually mount on the other side, so we are actually looking at the bottom of the board. This is important when mounting transistors and IC's.

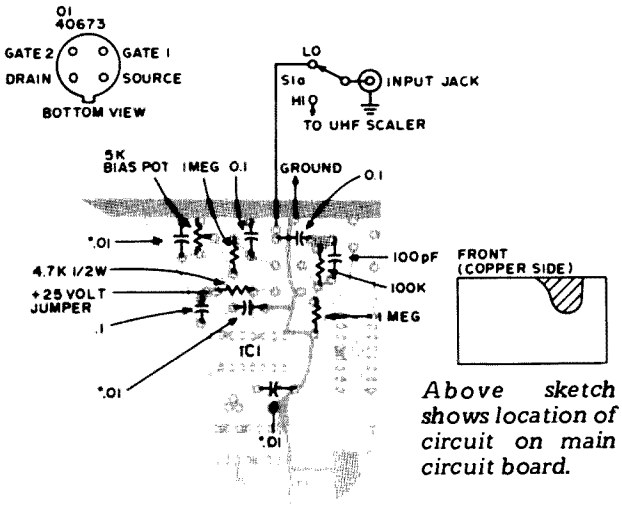

Figure 20 shows the 0–20 MHz input circuit. Transistor Q1 is shown as a bottom view at the side; the important thing to notice is the orientation of the little tab on the transistor case. Notice also that the IC's have to be inserted in a certain way – there is usually a little notch or depression at one end of the IC body, on the side that has pin 1. We have marked the position of this notched side on the drawings with a small half-moon. Furthermore, the drawings and the board have a small dot next to pin 1. Starting at pin 1, the pins are numbered consecutively down that side, and then back along the other side. IC1 is a seven-pin IC, and so it has pins 1 to 7 along one side (starting from the terminal near the dot), and pins 8 through 14 back along the other side. Pin 8 is on the same end as pin 7, and pin 14 is on the same end as pin 1. Some of the IC's have 16 pins, with pins 1 to 8 along one side, and 9 through 16 returning back along the other.

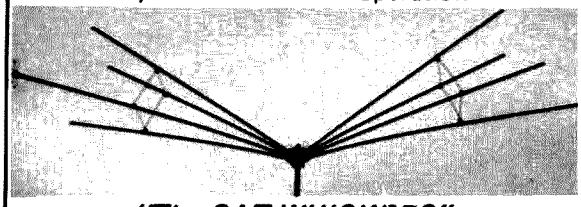
Incidentally, IC sockets of one kind or another are a must for a project like this. We don't want to scare you, but occasionally an IC is defective, or for some reason you have to troubleshoot the board, and removing an IC that has been soldered on the board is a pain in a place pills can't reach. There is also another reason for sockets, and that is that some of the IC's on the board do not have all their pins connected. In order to leave more room for connections at the bottom, these pins aren't brought through the board. That means you have to remove these pins on the IC socket – it's not a good idea to start cutting pins on the IC's themselves.

Since IC sockets can be quite expensive (even more expensive than some of the IC's themselves), we suggest a product called Molex Soldercon IC terminals, or just

MOLEX pins. These are individual little clips, one for each IC pin, which come in long strips joined by a connecting strip. You break off as many as you need (such as a strip of 7 for one side of a 14-pin IC), insert the whole strip into the board and solder, and then snap off the connecting strip. This leaves seven independent little clips, standing up from the board. Put another seven on the other side of the lineup, and you have fourteen clips, ready to plug in the IC itself. It's essentially the same as a regular socket, but without the plastic to hold it all together. The big advantage is cost – at about 1¢ a pin, you have a 14-pin socket for 14¢, instead of the 50¢ or more for a regular socket. There's another good reason as well – with a regular socket it sometimes happens that one of the pins doesn't make it through the board. Unless you notice it before you solder, it's an awful job to fix up the mess later.

But back to Fig. 20. The way the input jack is shown, an input signal at the jack is fed to switch Sla, and then to either the low-frequency circuit or the VHF scaler, depending on the position of the switch. S1



Above sketch shows location of circuit on main circuit board.

*Fig. 20. 0–20 MHz (low frequency) input circuit. Notes: 1. See Fig. 3 for diagram; 2. Capacitors marked * are bypass capacitors not shown on diagram. 3. Omit S1 if no VHF scaler installed.*

is actually a DPDT switch, with the other pole shown in Fig. 22. If you want to simplify the switching, you might eliminate the part of S1 shown in Fig. 20 and use two separate input jacks instead. This might have

LEE ELECTRONIC LABS. INC.
88 Evans Street
Watertown, Massachusetts 02172

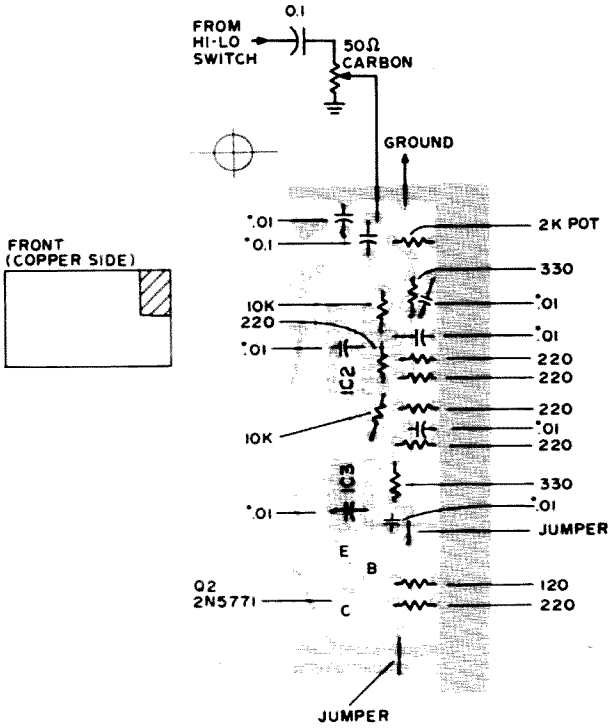

*Fig. 21. VHF prescaler circuit. Notes: See Fig. 4 for diagram; 2. Note the two 0.1 disk capacitors between pins 5 and 12 of IC; 3. Capacitors marked * are bypass capacitors not shown on schematics.*

the advantage of allowing you to hook up the counter to two different places, and measure the frequency at either by just flipping S1.

Figure 21 shows the VHF scaler circuit. If you are not including the scaler in your counter, then simply omit all parts in this figure, and omit S1 as well, wiring up the input jack directly to the low-frequency input circuit instead. Otherwise, the VHF scaler is pretty much standard. Make sure,

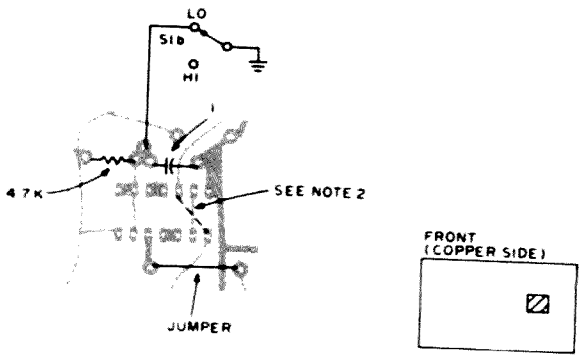

Fig. 22. Input selector circuit. Notes: 1. See Fig. 5 for diagram; 2. If no VHF scaler is used, this circuit is not needed. Omit all parts shown and jumper pins 5 and 8 as shown by dashed line.

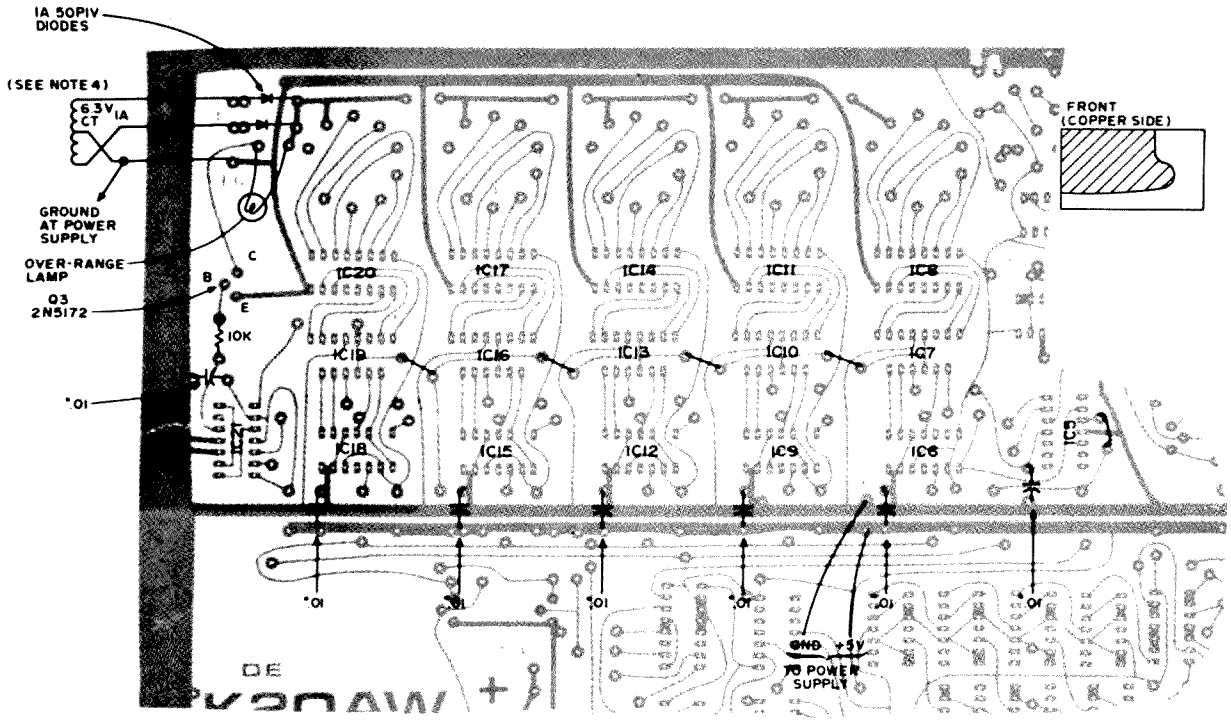
here as elsewhere, to place all parts right down against the board with the shortest leads possible. Notice also the two small 0.01 μF capacitors mounted underneath the two IC's. After you solder in the IC sockets (they go on top of the board), solder the two capacitors on the bottom of the board to the two pins shown (pins 5 and 12), using the shortest leads you can. The capacitors should be bent down tight against the underside of the board.

Figure 22 shows the input selector, needed only if the VHF scaler is installed. If not used, just omit all the parts shown and jumper pins 5 and 8 on the IC pads.

Figure 23 shows the major part of the board, containing the counters, latches, decoders, and over-range circuits. This part of the board will keep you busy for a while, since it has 37 wire jumpers. Make sure that these jumpers are as short as possible, flat against the board.

Shown at the left of Fig. 23 is all the circuitry for the over-range indicator and the power supply for the Numitron or Minitron readouts. As pointed out last month, we need a separate supply for these incandescent readouts, but not for LED readouts. Hence if you decide to use LEDs, you can omit the transformer and the two diodes. You can also omit Q3 and 10K resistor, since the LED over-range indicator can be driven directly off the output of IC21, pin 13, as shown in Fig. 28. Incidentally, if you are using LEDs, you can also omit the four jumpers at the very front of the board, connecting pin 2 of all the Numitron sockets, but don't forget the ground to terminal LG, which connects to the system ground all the way back at the +5V power supply.

Figure 24 shows the 10 MHz crystal oscillator and the time base dividers. Only two comments here. Note the short jumper runnning under IC24 and IC28. Put this jumper in before putting in the IC sockets, to make the work easier for yourself. Second, when putting in the 10 MHz crystal, leave the leads on it about 1/2" long. As pointed out in the first part of the article, someday you may want to place the crystal in an oven, and at that time you'll appreciate this.



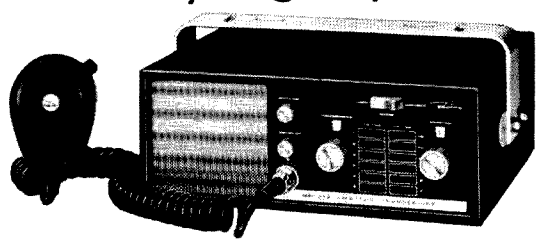


*Fig. 23. Counters, latches, decoders and over-range circuitry. Notes: 1. See Fig. 6 for diagram; 2. There are 37 jumpers shown — don't miss any; 3. Capacitors marked * are bypass capacitors not shown on diagrams; 4. Q3, transformer, diodes and associated parts not needed for LED readout.*

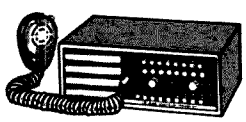
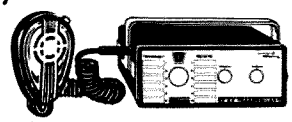
Regency 2 Meter FM—American made at import prices

NEW **Instant access to 144 frequency pairings with 20 watts out on the new HR-212 twelve channel 2 Meter FM Transceiver by Regency**



Specifications

Power Output: 20 watts (nom.) at 13.8 V DC
Frequency Range: 144-148 MHz
Channels: 12; crystal controlled
Sensitivity: 0.4 uv, 20 DB quieting
Spurious Rejection: 60 DB



Model HR-212 **$259 Amateur Net**
Includes microphone, mounting bracket and factory installed transmit and receive crystals for 146.94 MHz.

Huntington Beach, Calif. 92646

Figure 25 shows the time base selector and control circuits. Note again two jumpers running under IC sockets, as before. Make sure that the switch is connected as shown. The lead to the switch can be a single unshielded lead, running either under or over the board, up to the front panel. Virtually any silicon NPN transistors can be used for Q3, Q4, and Q5 as long as they have reasonably good gain, but we suggested the 2N5172 since it is very cheap.

Figure 26 shows the +25V supply, mounted in a corner of the main board. As shown, the circuit is designed for a 38V center-tapped transformer, and uses a full-wave rectifier. If you have a 16- to 20V transformer, add two diodes as shown and eliminate the centertap. This makes the circuit a full-wave bridge. Watch the polarity on the electrolytic, and use a 50V unit, not a 25V unit!

As part of the +25V supply, you will need a long jumper from the 25V terminal over to the 4.7K resistor near Q1, shown at the left of Fig. 20.

As mentioned earlier, the easiest readout to use is the Numitron; just install 9-pin miniature tube sockets on the board and plug in the readouts. In one of our prototypes, however, we used LEDs because of their good looks. Figure 27 shows the LED readout board for mounting them. In addition to MOLEX pins or 14-pin IC sockets, you will need 35 150Ω resistors for current limiting. The over-range indicator also

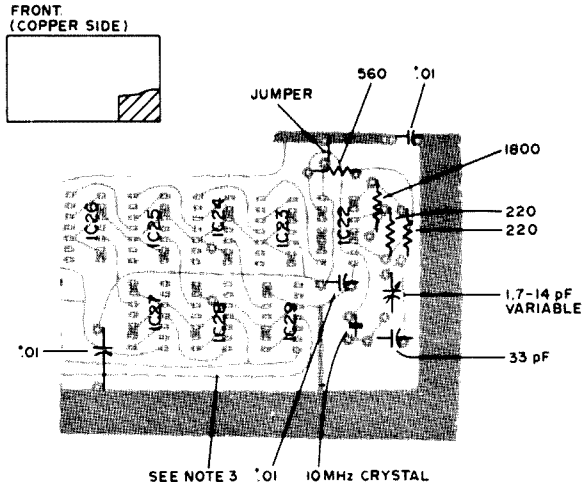

*Fig. 24. 10 MHz crystal oscillator and time chain divider circuits. Notes: 1. See Figures 7 and 8 for diagram; 2. Capacitors marked * are bypass capacitors not shown on diagram; 3. Note the jumper running under IC24 and IC 28.*

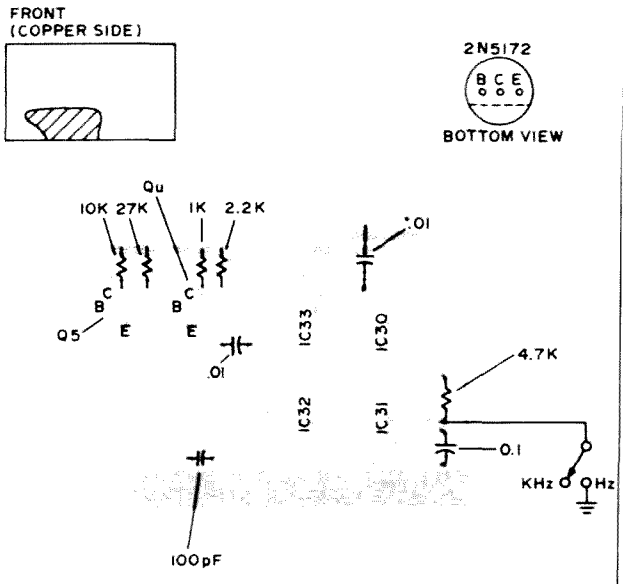

*Fig. 25. Time base selector and control circuits. Notes: 1. See figures 9 and 10 for diagram; 2. There are 11 jumpers shown — note especially the jumper running under IC32 and IC33; 3. Capacitor marked * is a bypass capacitor and is not shown on diagrams.*

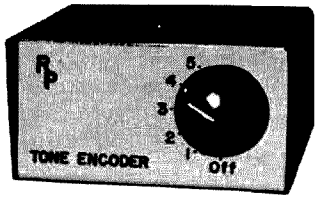
mounts on this board; the board has room for two over-range indicators, one above the other, to make a sort of : (colon) arrangement, but only one is really needed. For LED over-range indicators you will also need 220Ω current limiting resistors. If you decide to use incandescent over-range bulbs, then follow the hookup as shown in Fig. 23, but you will need a spearate source of lamp voltage. It seems to be the hard way.



To connect the LED board to the main board, note the letters cgdaebf on the LED board, on one of the 9-pin sockets on the main board, and in Fig. 15. The actual connections are shown, for one LED indicator, on Fig. 28. The cgdaebf terminals for each LED connect to the like terminals on the main board, to the corresponding 9-pin socket. The over-range LED connects to pin 13 of IC21, through the 220Ω resistor, the 5V terminal on the LED board goes to +5V at the power supply, and the LG terminal goes to the ground terminal, also at the power supply. If you use two LEDs for over-range we suggest using Q3 and the 10K resistor, and connecting the 120Ω resistors to Q3 at point X, as shown.

After wiring up the main board, but before installing the IC's in their sockets, we suggest that you examine the board carefully

NEW from RP

TONE BURST ENCODERS

- UP to 5 fixed tones (factory set)
- ADJUSTABLE:
  —Duration
  —Output
- NO BATTERIES needed.
- FULLY ADAPTABLE

for good solder joints and no shorts. Hopefully you used a small pencil iron, such as a 30-watt Ungar, and good solder. We like 60% tin, 40% lead (not the other way around!) solder of the thin variety. If you scrub the board with Brillo soap pads just before starting construction, to clean off the copper, you should have no trouble soldering to it with a minimum of heat and solder.

Once construction is done, check for shorts. Use an ohm-meter to check between ground and the +5V connection point shown in Fig. 23. With all the IC's out, you should get a high reading – at least several hundred ohms.

Now is also the time to build the power supply. After you finish it, make sure to test it and, if needed, adjust the output voltage to +5V before connecting to the main board. An over-voltage can ruin a lot of expensive IC's

Once everything is hooked up, take the big step and turn on the main power. If all the indicators read 00000 you will probably breathe a sigh of relief, but all is not done yet. With luck, your counter should now be working. Except for two bad connections, our second prototype worked right away. Just in case that your counter doesn't work and you need to do some troubleshooting, here is a suggested way of going about it. You will probably need a scope, though.

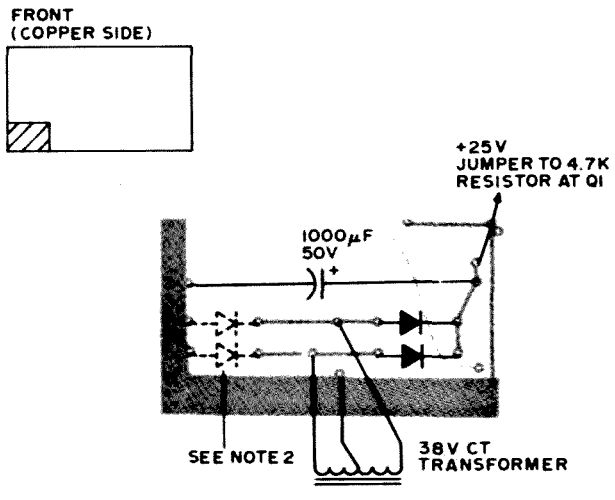

Fig. 26. +25 volt power supply. Notes: 1. Circuit shown in diagram in Fig. 17; 2. Supply is designed for a 38V CT transformer – if a 16–20 v transformer is used, disconnect centertap and add two diodes as shown dotted, thus converting the rectifier into a bridge.

First, check the 10 MHz oscillator and time chain dividers. Put a meter (20,000Ω per volt VOM) at IC23 pin 11. The meter should swing up and down at the rate of one cycle per second. If so, fine. If not, use a scope to trace the signals through the circuit. Check the points in Table I for the signals shown.

TABLE I

Signal	IC	Pin
10 MHz	22	8
1 MHz	23	11
100 kHz	24	11
10 kHz	25	11
1 kHz	26	11
100 Hz	27	11
10 Hz	28	11
1 Hz	29	11

If no 10 MHz signal appears at IC22, interchange the SN7400N IC with one of the others in the counter. If the signal seems to go down the line but stops at some point in the divider chain, interchange the affected SN7490N with another. In this way, you should be able to get the oscillator and divider chain working.

Next step, if everything is OK so far, is to check whether the indicators light. If not, check the power connections to the indicators, and the ground and +5V connections to the SN7447N decoder/drivers. If some indicators light and others don't, interchange IC's and indicators (with the power off!) to try to narrow down the cause. If interchanging the IC's doesn't do it, check your connections.

Once the indicators light, they will probably read all zeroes. Place the Hz–kHz switch in the Hz position and turn off the power for about five seconds. When you turn the power back on, the indicators should come back with some really crazy readings, or perhaps even totally dark. It should take about two seconds for them to reset back to zero. This is because the flip-flops in the counters and latches come back in random states, and it normally takes two seconds to get everything reset back to zero. If this occurs as described, fine. Otherwise check the control circuits for wave-

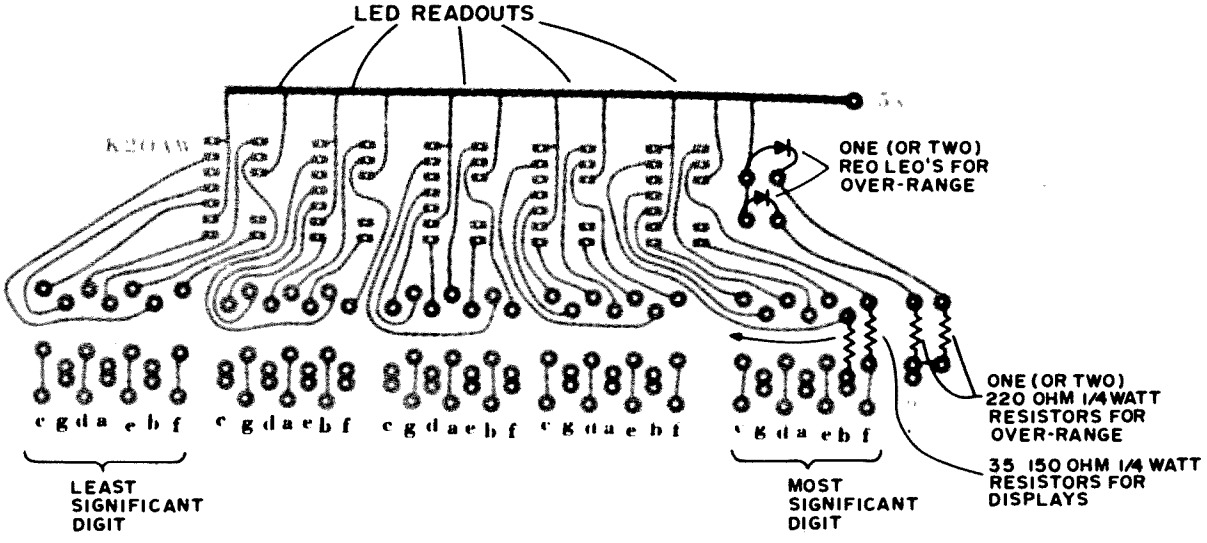

Fig. 27. Rear view (copper side) of board for mounting MAN-1, 10A, or LED-700 readouts.

forms similar to those in Figs. 11 and 12, depending on the position of the Hz–kHz switch. Unless you have a really good scope, you may not be able to see the thin pulses on the reset and strobe lines.

Once everything seems to work OK, remove IC4, and connect a short wire to pin 8 of the socket. Place the Hz–kHz switch in the kHz position, and use the wire to trace the signals listed in Table I, starting at 1 kHz and going up in frequency. The 1 kHz signal should result in a reading of 00001 on the displays, the 10 kHz should result in 00010, and so on. Go through all five counters like this, checking for a 1 in each place. If everything works fine at lower frequencies, but not at the higher frequencies, check the SN7490N counter at the right most position that doesn't work by interchanging it with another to its right – don't go back and swap IC's in the time chain dividers, though – leave well enough alone. If most of the readings here are OK but one of the digits in the center does not seem to work, check the counter, latch, and decoder as well. If you use any readout other than the Numitron, and get some strange readings, check the wiring between the readouts and the main board for a mixup.

Once you have gone this far, you are pretty close to being home. Try both input circuits. If one input works and the other doesn't, that should narrow down the trouble. If neither works, check the circuitry around IC4. Check also the wiring to S1 – you may have the wiring mixed up so that the input of one of the two input circuits is connected at the same time as the output of the other. You won't get too many signals through that way.

Once everything is working, readjust the 2K and 5K pots for best sensitivity. Don't be

MINIATURE
SUB–AUDIBLE
TONE
ENCODER

- Compatible with all sub-audible tone systems such as Private Line, Channel Guard, Quiet Channel, etc.
- Glass Epoxy PCB, silicon transistors, and tantalum electrolytics used throughout
- Any miniature dual coil contactless reed may be used (Motorola TLN6824A, TLN6709B – Bramco RF-20)
- Powered by 12vdc @3ma
- Use on any tone frequency 67Hz to 250Hz
- Miniature in size 2.5x.75x1.5" high
- Wired and tested $14.95
- Complete less reed (Available in 33 freqs. for $17.50 ea)
- Output 3v RMS sinewave, low distortion
- Postpaid – Calif. residents add 5% sales tax

surprised if the VHF input shows some reading even with no input connected. This indicates some oscillation in the input amplifier, and you can easily eliminate it by slightly moving the setting of the 2K pot. We've seen even some fairly expensive commercial counters do this, and the oscillation usually gets swamped out when an actual signal is connected.

The inputs are actually quite sensitive. We have a local radio station on 1310 kHz a mile or so away, and we often notice the counter with a 01310 indication when connected into a circuit which has its power turned off. If you forget to connect the ground to the input of the counter, you may often see a 00060 reading in the Hz position – that's just plain hum. It's nice to know that your local electric company keeps its frequency on the nose.

Speaking of frequency, there is one more adjustment to be done, and that is zeroing of the 10 MHz oscillator against WWV. This is quite simple, as the counter puts out a nice 10 MHz signal with the case off. If you find that the crystal won't quite go to 10 MHz, you can change the value of the 33 pF capacitor in parallel with the trimmer capacitor as needed. If you can't receive WWV, then you might connect another (calibrated!) counter to the 10 MHz signal and adjust that for the right frequency. Heathkit has another trick in their instruction manual for their counter, and that is that you place an ordinary transistor AM radio near the counter, and tune to a broadcast station. Since the counter puts out strong signals at 10 and 20 kHz as well, the harmonics of these will beat with the station. Since the FCC requires commercial stations to be close to their assigned frequency, which is always on a multiple of 10 kHz, you can zero beat the counter against the station. But pick a station which you know to have a good engineering staff, not your local college run station run by sleepy-eyed undergraduates.

And don't let your friendly envious hams talk you into calibrating your counter with a borrowed BC-221 frequency meter! Try a little one-upmanship and offer to them first.

I'd like to thank Mike, WB2AAQ, for his help in building one of our prototypes.

FREQUENCY SYNTHESIZER FOR 2M FM: Part I

One of the major expenses in going on 2-meter FM is the price of crystals. Even so, it seems you never quite have the right ones. Well, here's the device to eliminate all that – a frequency synthesizer which lets you hop all over the band.

The complete information to enable you to build your own will be presented in three parts. This month we will give a complete description of what the synthesizer is and what it can do, along with a block diagram and simple description of how it works. If you decide to go ahead with building it, there's a complete parts list at the end of this installment. Next month we give the diagrams and the detailed theory of operation. The month after that we will have the printed circuit board layout, parts layout drawings, and construction and operating information.

And now a little information about the unit:

1. The complete price should be under $100, depending on where you get your parts. We will have some information on parts sources in the parts list later.

2. The unit covers from 145 to 148 MHz in steps of 5 kHz. With a few modifications the range could be extended down to 144 MHz, but that complicates the switching and so we decided against it.

3. It is inherently quite stable. It has only one crystal, at 10 MHz. Once you beat this crystal against WWV all other frequencies automatically fall in line.

4. The synthesizer can be used for both transmitting and receiving, with a choice of two-frequency operation. That's a necessary feature for working through repeaters, since you can transmit on one frequency and receive on another.

5. It is designed as a crystal substitute. You merely plug the synthesizer output cables into the crystal sockets of your rig. It is not a complete transceiver by itself.

6. It is designed to operate with most common amateur two-meter transceivers. The unit could also be used with most commercial transmitters of the GE/Motorola class, but you'd have to make some changes to use it for reception as well. The synthesizer is designed for receivers having either 10.7 or 11.7 MHz i-f frequencies with low-side first oscillator injection, which pretty well limits it to use with the more popular amateur-only transceivers.

7. Since the synthesizer is only a crystal substitute, your regular transceiver is used for all other functions (such as modulation). But in case you have an AM rig, it is possible to FM modulate the synthesizer itself. That will give you an FM signal. In our prototype

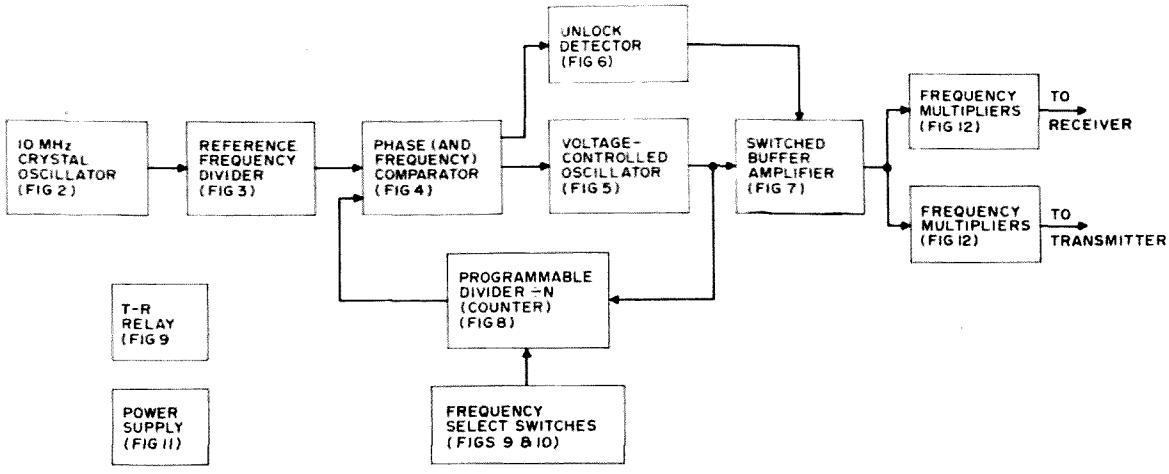

Fig. 1. Frequency Synthesizer

we had a little extra room in the case, and so we decided to install a touch-tone pad, which modulates the synthesizer. We plan to put in a tone-burst encoder and PL (snythesized?) at a later time.

8. We went out of our way to make the project easy to build. Except for the power supply, switching, and output buffers and multipliers, everything else fits onto a 7" x 9" printed circuit board. The p.c. board layout and etched boards are available to make your job even easier.

The requirement that the synthesizer work with a variety of transceivers makes the design a bit awkward, since different transceivers use different crystal frequencies. You can ignore the circuit capacity that your unit is designed for, since that has no effect on the output frequency with the synthesizer, but the crystal frequency itself (and the equation used to calculate it) is an important factor. Table I lists the requirements for several common amateur transceivers. As you can see, the actual crystal frequencies range from 6 MHz to 45 MHz. Most of the rigs use a 10.7 MHz receive offset, except that the Standard uses 11.7 MHz; this requires a small change to the synthesizer. (The new Swan FM 1210-A uses 16.9 MHz offset. You'd have to make a number of changes to adapt the synthesizer to that rig.)

As you can see in Table 1, most of the transmit crystals are 8, 12, or 18 MHz (the older Regency HR-2 uses 6 MHz rocks). We decided to build our unit to output at 6 MHz, which can easily be doubled to 12 or tripled to 18 MHz. If you need 8 MHz, then you will have to change the design a little to output at 8 MHz directly. It is also possible to modify the synthesizer to output directly at 12 MHz, but it's easier to take the 6 MHz output and double it.

As for receiving, most rigs use 45 MHz rocks. You can start with 6 MHz and multiply by 8, start with 8 MHz and multiply by 6, or start with 12 MHz and multiply by 4. The 15 MHz signal needed by the Standard can be obtained from 8 MHz by doubling. But keep in mind that if you plan to use the synthesizer for both receive and transmit you have to pick a common frequency output. You can't pick 6 MHz output if you need 15 MHz for the receiver, since you can't double or triple 6 to get 15. Since 6 MHz seems to be the most useful with the widest variety of units (including our Varitronics IC-2F and an old Pre-Prog transmitter) we decided to design for that.

TABLE I

Crystal Frequencies for Common Transceivers

Unit	Transmit Formula	Transmit Freq.	Receive Formula	Receive Freq.	Synthesizer Output
Varitronics IC-2F	$\frac{f}{8}$	18 MHz	$\frac{f-10.7}{3}$	45 MHz	6 or 12 MHz
Varitronics IC-2F	$\frac{f}{8}$	18 MHz	$\frac{f-10.7}{3}$	45 MHz	6 or 12 MHz
Drake	$\frac{f}{12}$	12	$\frac{f-10.7}{3}$	45	6 or 12
Standard SRC-826M SRC-146	$\frac{f}{18}$	8	$\frac{f-11.7}{9}$	15	8
Swan FM-2X	$\frac{f}{12}$	12	$\frac{f-10.7}{3}$	45	6 or 12

The rest of this article describes the 6 MHz version, but wherever applicable we will tell you the applicable information for the 8 or 12 MHz versions. If so, the additional information will always be in parentheses, following the 6 MHz information.

And now on to details. Figure 1 shows the block diagram of the overall unit. The individual diagrams for each block will be shown next month, and the block diagram gives the figure numbers for each detailed diagram.

The heart of the unit is the voltage-controlled-oscillator which we will simply call the VCO from now on. The VCO actually generates the 6 MHz (or 8 or 12 MHz) output frequency. This signal is fed into a switched buffer amplifier and then into the frequency multipliers needed to generate the correct crystal frequencies for your rig. Two sets of multipliers are usually needed, one set for the transmit frequencies and one for the receive frequencies.

All the rest of the synthesizer is used as an automatic frequency control to keep the VCO on frequency. The correct terminology is actually to call it a phase-locked-loop (PLL). This is done by a feedback loop which compares the VCO output frequency with a crystal-generated reference frequency in the phase (and frequency) comparator. It is used here as a frequency comparator, but since it works by actually comparing phases it is called a phase comparator.

Since the crystal frequency and the VCO output frequency are not the same, we can't really compare them directly. Instead, we take the 10 MHz crystal frequency and divide it by a factor of exactly 48,000 in the reference frequency divider to get 208-1/3 Hz (in the 8 MHz version we divide by 36,000 to get 277-7/9 Hz, and in the 12 MHz version we divide it by 24,000 to get 416-2/3 Hz).

At the same time, we take the VCO output frequency and divide it by another number, N. But this division is done in a programmable divider, and the exact number by which we can divide is changed by the

EXPERIMENTING IN FACSIMILE?
The leading manufacturer of 18" facsimile weather chart recorders is in the process of converting an existing network for fully automated weather chart transmission. This conversion will make available a number of used 18" weather map recorders ideally suited for use by anyone interested in experimenting with facsimile.
They include the recording head, all necessary electronics including automatic start, phase and stop circuits. Operating at speeds of 60, 90 or 120 rpm (depending on model), these recorders, with suitable receiver and FSK converter, can be used to monitor radio weather chart broadcasts from stations located around the world or modified to accept press wire photo transmissions or modified to receive transmissions from orbiting weather satellites.
These recorders are available strictly on a first-come, first-served basis.

frequency Select Switches. Suppose we want an output on 145.000 MHz. Then the switches are wired in such a way that the progrmmable divider divides by exactly 29,000. Then the divider takes the VCO output frequency, divides it by 29,000, and sends the result to the phase comparator.

The phase comparator looks at the two frequencies it gets. If they are exactly the same, nothing happens. But if the frequency coming out of the programmable divider is too low, the phase comparator decides that the VCO frequency is too low also, and sends a control signal to the VCO to increase its output frequency. In the same, way, if the frequency fed back from the programmable divider is too high, the phase comparator forces the VCO frequency down. In this way the phase comparator controls the VCO in such a way to make the output from the programmable divider the same frequency as the output from the reference frequency divider. This is the automatic frequency control action.

Now, if the output of the VCO, divided by the number N, is equal to the reference frequency, another way to look at it is that the output of the VCO is the reference frequency times N.

Using the 6 MHz synthesizer as an example, if we set the switches for 145.000 MHz output (so that N is 29,000), then the output from the synthesizer is the reference frequency (208-1/3) times N (29,000). If you multiply this out, you get exactly 6.041667 MHz. This is the exact 6 MHz crystal you would need to multiply up to 145.000 MHz. (If you want to do a little work, you can multiply 29,000 by the reference frequencies used in the 8 or 12 MHz synthesizer, to check that you get the right output frequency.)

Since the phase-locked-loop forces the VCO output frequency to equal the reference frequency times N, the way we get various output frequencies to cover the range from 145 to 148 MHz is to change N. This is done with eight front panel frequency selection switches. Just as an example, at several typical frequencies we have the following:

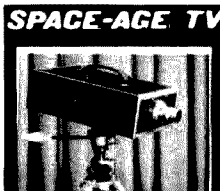
BRAND NEW FREQ-SHIFT TTY MONITOR:
NAVY OCT-3: FM Receiver type, freq. range 1 to 26 MHz in 4 bands, cont. tuning. Crystal calib. Reads up to 1500 Hz deviation on built-in VTVM. Cost $1100.00 each! In original box, with instruct. book & cord, fob Mariposa, Cal. Min. signal needed: 15 mv. Shpg wt 110 lbs **49.50**

HIGH-SENSITIVITY WIDE-BAND RECEIVER
COMMUNICATIONS ● BUG DETECTION ● SPECTRUM STUDIES
38-1000 MHZ AN/ALR-5: Consists of brand new tuner/converter CV-253/ALR in original factory pack and an exc. used, checked OK & grtd main receiver R-444 modified for 120 v. 50/60 hz. The tuner covers the range in 4 bands; each band has its own Type N Ant. input. Packed with each tuner is the factory inspector's checkout sheet. The one we opened showed **SENSITIVITY:** 1.1 uv at 38.4 mhz, 0.9 at 133 mhz, 5 at 538 mhz, 4½ at 778 mhz, 7 at 1 ghz. The receiver is actually a 30 mhz IF ampl. with all that follows, including a diode meter for relative signal strengths; an atten. calibrated in 6 db steps to −74 db, followed by an AVC position; Pan., Video & AF outputs; switch select pass of ±200 khz or ±2 mhz; and **SELECT AM or FM!** With Handbook & pwr. input plug, all only **375.00**
CV-253 Converter only, good used w/book.....**99.50**
STODDART NM50A Receiver 300–1000 mHz . . . 195.00
We have SP-600-JX, R390, WRR-2 Receivers. Ask!
SENSITIVE RECEIVERS from 3 kHz to 75 gHz . . . ASK!

REGUL. PWR SPLY FOR COMMAND, LM, ETC.
PP-106/U: Metered. Knob-adjustable 90-270 v up to 80 ma dc; also select an AC of 6.3 v 5A, or 12.6 v 2½ A, or 28 v 2½ A. With mating output plug & all tech. data. Shpg. wt. 50 lbs. **19.50**
BARGAINS WHICH THE ABOVE WILL POWER:
LM-(*) Freq. Meter: 125–20 MHz, .01% CW or AM, with serial-matched calib. book, tech. data, mating plug. Shipping wt. 16 lbs **37.50**
TS-323 Freq. Meter: 20–480 mhz. 001% **49.50**
R23A/ARC5 Command Q-5'er 190–550 KHz, exc. cond **16.95**
A.R.C. R15(MIL R-509)Command, 108–135 MHz,new **17.50**
Meas. Corp. #59 Grid Dipper 2.2–420 mHz 75.00



NEMS-CLARKE #1670 FM Rcvr 55-260 MHz like new **275.00**
WWV Rcvr/Comparator 2½–20 MHz, w/scope . . **250.00**
Empire Devices NF-114 RFI meter is a red-hot receiver from 150 KHz to 80 MHz **295.00**

1301 N. BROADWAY **ATV Research** DAKOTA CITY, NEBR. 68731

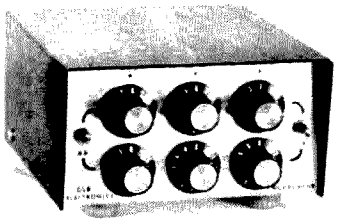
at 145.000 MHz, N is 29,000
at 145.005 MHz, N is 29,001
at 145.010 MHz, N is 29,002
at 146.940 MHz, N is 29,388
at 147.995 MHz, N is 29,599.

As you can see, changing N by 1 changes the output frequency by exactly 5 KHz, thus giving us the 5 KHz channel spacing. If we make the programmable divider adjustable so N goes from 29,000 to 29,599, that will cover the entire 3 MHz of the band.

Since each count in the programmable divider changes the output by 5 KHz, if we subtract 2140 from N during receiving we will automatically drop the output by 10.7 MHz. (To use an 11.7 MHz receive i-f offset, we subtract 2340.) This subtraction is done automatically by a T R relay. In fact, the switches can be wired to indicate the actual channel frequency. It is not necessary to figure out the value of N corresponding to the operating frequency – if you want to transmit on 146.340, just set the four transmit switches to the digits 6340. To receive on 147.015, just set the four receive switches to 7015. It's that simple.

When you use the synthesizer for transceiving, the VCO has to switch back and forth between two frequencies every time you push or release the mike button. As with any feedback system, this takes a little time. In the synthesizer, it takes the VCO about ¼ to ½ second to reach and settle on the new frequency. To make sure that you don't transmit on the wrong frequency during this interval, an unlock detector monitors the phase detector output, and turns off the switched buffer amplifier while the VCO is moving to the new frequency. This makes it a little rough to break into conversations, but we've researched the problem and, short of having separate synthesizers for receive and transmit, there seems to be no way of getting around the problem. We could reduce this time below ¼ second, but only by greatly complicating the unit and upping the cost.

Next month we will continue with more info.



. . .K2OAW

(Continued from page 9)
a hold and the speaker wires are right there ready.

The power cord comes with a jack built into it – handy for taking the rig out for changing crystals or using it in the house. You can use one crystal for two or more channels if you are a cheapskate too, with a simple cross wire which you can install in seconds – or take out. This is nice for things like 34–94 and 94–94 pairs.

With all the features one might expect this unit to sell for well over $300 – so it will probably boggle a lot of minds to find that this power house sells for only $249.95. It's the most powerful rig you can buy today unless you get an outboard amplifier. *General Avaiation Electronics, Inc., 4141 Kingman Dr., Indianapolis IN 46226.*

GLB SYNTHESIZER

The GLB Electronics model 400B synthesizer is now beginning to become available to dedicated FMers. This synthesizer is designed to work with most of the popular ham FM transceivers and make them so they can hit any 10 kHz frequency on transmit and receive in the entire two meter band, from 144–148 MHz.

There are two sets of dials for setting the frequencies. One set is used for transmitting channels and the other for receive . . . plus there are switches to reverse this order if you happen to feel like it. Or you can use one set to transceive, if that turns you on.

Once you have plugged the 400B into your transceiver and programmed its output to match your rig's crystal requirements, all you have to do is switch from any channel to any other at will. If you want to use a 31–91 repeater you switch the transmitter dials to 6–3–1 and the receiver dials to 6–9–1. It is that simple! Perhaps you want to check the reverse pair? One flip of the two toggle switches and you are listening on 31 and transmitting on 91. That's handy at times.

The specifications that come with the unit have a lot of details that might interest you, though they have little to do with the use of the unit. Like it uses 350 mA at 10–15V dc . . . takes about 10 milliseconds to lock up between receive and transmit . . . uses the push-to-talk from the transceiver . . . has a frequency stability of .005% . . . size 3" high, 5¾" wide, 6½" deep . . . has enough power to feed even fairly long cables, etc.

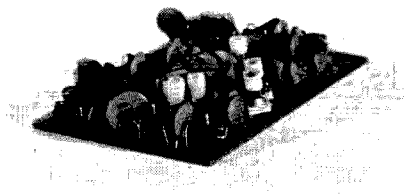
The model 400B sells for $130 in kit form and $190 assembled. More info can be had from *GLB Electronics, 404 Cayuga Creek Rd., South Cheektowaga NY 14227.*

The GLB part of the company name comes from Gil Boelke W2EUP and the project is an outgrowth of a group effort by the Buffalo repeater association. Gil has sneakily removed the IC numbers and substituted color codes on the eleven ICs in the unit, so don't expect that you can borrow a unit and make one up for yourself. I don't see much in the way of identification of the 14 or so transistors either.

While it is not quite as fast to work the two sets of switches as it is one channel switch, the total flexibility of the arrangement certainly makes up for the slight additional work. Every repeater is immediately within your reach – every simplex channel – every invert pair – no matter where you go. If you get into a new area you know you can still match anything they can dream up in weird pairs. . .even in Chicago and Los Angeles! – and that's saying a lot.

STANDARD SRC-826M UPDATED

Standard doesn't seem to even try to take advantage of their changes in design. Pity, for they have been making substantial improvements in the unit and the changes should be brought to the attention of the prospective customers.



The recent review of the 826 in *CQ* was particularly unfair, with a good deal of space being taken up airing complaints over problems that have been surmounted for quite a long time. The fact is that the Standard equipment that has been sold for the last couple of years has been of excellent quality.

The current model 826 has been changed so that the crystals are right out there in the open when you open a little door in the cabinet. You don't even have to take the rig out of the case to change or tweak crystals now.

Sometime in the last year the 826 crystal deck was changed from its previous vertical position to horizontal. This was a major improvement since it made it infinitely simpler to get in there and tweak those trimmer capacitors. The older model required the services of a malformed dwarf to get into the trimmers – the horizontal board cured all that, putting the capacitors where anyone could reach them. The new door just makes it even easier.

Standard is a bit evasive about the i-f filters they are using, but there is good reason to believe that they have been sending their units along with ever narrower filters. The 826 may have the narrowest i-f on the market today. This makes a big difference when the set is to be used in a major city where the rf pollution is high and where there may even be a 146 MHz repeater output within 30 kHz of the desired channel. Many sets fall apart under these conditions. In situations such as this the reason for paying a bit extra for a transceiver becomes very apparent. *Standard Communications, 639 N. Marine Ave., Wilmington CA 90744.*

2mFM FOR $35.00

As impossible as it seems, there is now a neat little two meter FM transmitter on the market for only $35 – and that is complete with crystal and microphone. We found it difficult to believe at 73 when we received the first announcement of this rig, so we sent for a few of the transmitters, just to see. Sure enough, they arrived, complete with crystals and microphones, ready to go for the frequencies we had specified.

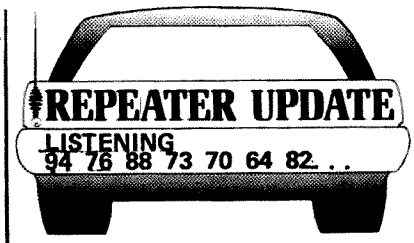
The rig has ten transistors and is built on a pc board only 2½" x 3" – the whole thing is about 3/4" thick, so it could easily be squeezed into a hand unit . . . or into just about any 2m receiver to make it into a transceiver. It uses an 8 MHz crystal (the crystals for the Standard transceivers will work just fine in it if you want to use more than the crystal that comes with it) and has three triplers, a buffer and power amplifier. The final runs about 0.1 watts with 8 volts on the unit and will go up to a full watt if you run the voltage up to 12 volts – and add some heat sinking to that output transistor. But why run high power when low will do the job, right? The 100 mW seems adequate for most line-of-sight applications.

It took about five minutes to solder some wire leads to the board for the 8 volt power (transistor 9V battery), a 19" "antenna" to the output terminal, and hook in the mike. The rig took off immediately and put out a beautiful signal. Tests were made through nearby repeaters – good reports. A couple of days later, Bill, W1PFA, had one of the little rigs working through the K1MNS repeater.

One of the first "conversions" on my units was to remove the soldered-

in crystal and put in pin sockets so regular FM crystals could be plugged in to change the frequency. That took about five minutes. Next I wired in a little transformer to step down the audio input impedance so I could feed the rig from a receiver and make a midget repeater out of it. For a few days I drove every passing amateur crazy with my tiny 34–94 repeater. It covered Peterborough nicely, which was what I had in mind. That little rig could do a fine job as a low powered repeater if I put it up on the mountain. I note that the German repeater on the Zugspitz has only been running about two watts, and has been used over 200 mile paths.

Perhaps, with the era of these extremely low cost rigs, we may find one-town repeaters becoming popular – perhaps even mobile repeaters may be next.



The amateur interested in simple construction could take this little rig and build it into a hand unit quite simply. He might add a little transistor radio and converter – or perhaps he might work on International Signal to release the receiver boards they make.

These boards are made in the U.S.A. by the same company that puts out the Clegg equipment. They were originally designed for being built into fire hats to provide communications for firemen. When that project was cancelled, International Signal found themselves sitting there with a few hundred midgit transmitters and receivers. Hmmm, they said, would the amateurs be interested in cleaning out these leftovers? They sent out a trial letter to a few hundred known FMers and the answer was a resounding YES! The rigs disappeared instantly. Hmmm,, they then thought – let's see what happens if we advertise them in 73.

At $35 this has to be one of the best bargains ever to hit for the FM amateur.

There has been some talk of using these inexpensive transmitters as another weapon in repeater wars. Imagine the consternation of the repeater mogul who has been crushing co-channel repeaters with high power when he finds that his repeater is being keyed up by short random pulses from well hidden things like this. It could take forever to find them. Such talk is irresponsible and such an approach to repeater problems should not even be considered. There is no King of Repeaters so arrogant that you cannot sit down face to face with him and work out your problems. Well, there may be one that arrogant – but only one, and he isn't *your* problem. No, let's be sure to use these almost throw-away priced transmitters for the benefit of amateur radio, not to further battles.

73 will welcome application ideas for these rigs – conversions – whatever. *International Signal, 3050 Hempland Road, Lancaster PA 17601.*

SOLID STATE REPEATER

Not a few repeater groups are fed up with the miseries of keeping tubes in their converted surplus type repeaters. And how many repeaters sit there and work, month in and month out without requiring almost constant attention? The availability at a very reasonable price of a trouble-free solid state repeater should be welcomed.

Standard Communications has put together a repeater package using the best commercial Standard boards which should be very popular. The unit operates from 12 volts, which means that in most installations there will be a power supply with a good sized storage battery across it – so in case of ac power loss the unit will be able to operate from the battery. The drain is low – about 400 mA on receive and 3 Amps on transmit.

The fellows at Standard have tried to put everything in the repeater that you will need . . . input for the identifier . . . adjustable time out timer . . . external speaker jack for testing . . . carrier delay timer for the squelch tail (or tale, if you like that better) . . . and a remote control jack. The repeater is designed for 19" rack mounting and is only 5¼" high and 9" deep. The output is ten watts – about right for the average repeater. Higher power is rarely needed except to meet the needs of the repeater owners ego and almost invariably leads to the alligator syndrome. If the temptation is just too much and you must have more power, the ten watt output will drive one of the amplifiers available from Tempo and others quite adequately. Tempo has an amplifier in the works designed for repeaters, built on a 19" panel.

There are local controls on the repeater to turn the receive on, the transmitter on, the squelch on, a volume control for the speaker, a repeat-duplex switch, monitor switch and a tone squelch switch.

The price? Under $600. Just barely. *Standard Communications, Box 325, Wilmington CA 90744.*

HOT GEAR

Saul A. Cohen, K4ACJ, reports the theft of a Swan Cygnet Model 270 transceiver S/N 313022 and a Collins MIC Model MMs S/N 4294. The equipment was stolen from his car in San Francisco on June 4.

LETTERS

ou goons don't ever proofr
l asy
bu ch of ro ks re n
you ignored my comments in
I insist that you print ev

For the past 3 or 4 years, I have been reading, off-and-on, every ham radio magazine I could find. Last year, a good friend introduced me to 73. Having seen them all, and read them all, I feel that 73 is just about the best there is. I therefore respect your opinions.

For some time, I have been studying for the license, but personal problems always restricted my time. Now I am finally catching up on my code.

Here's my question: If I can achieve 13 wpm (I think I can) would you suggest I try for a General rather than Novice? I have sufficient electronic background to pass the theory. I have heard various arguments for and against; some say that something is missed if one doesn't go through at least a few months as a Novice. What's your opinion?

Dan Case
Erie PA

It sure would be a shame to miss having to buy a bunch of equipment for the Novice bands that you won't need later as a General – and to miss out on the frustration of operating with crystal control (unless you get the Microcomm) . . . and all the other miseries that turn Novices away from amateur radio so they never even get a chance to find out how much fun can be had. Don't miss this educational approach to amateur radio.

I disagree with what was said by W7AR in his letter of July 1972. SSB is the most efficient way to transmit information. It takes up exactly the same amount of space in the spectrum as does the original information. The reason that we need so much spectrum space to carry voice (about 3 kHz) is the tremendous redundancy of speech. The redundancy has its advantage. As in all information transmission systems, redundancy helps eliminate errors. If we have a clear frequency and want to send the most information in the least time, using the minimum bandwidth, we are forced to go to a language with less redundancy. Such is the language of RTTY. With RTTY, you can send more information per unit time per unit bandwidth than you can with voice.

As we increase the bandwidth required by our signal, we increase either the speed of information or the redundancy of the signal. Therefore, I believe that the new breakthrough in communications will not be a new type of modulation, but rather a new language to apply to our old type of modulation.

The reason we don't divide down our voice frequencies for transmission, then multiply them back up upon reception can be explained in several ways. One is that it is not possible to send the same amount of information in the same amount of time on a narrower bandwidth. Another explanation is that all rf multiplication and division is done assuming that the signal is digital, either on or off. This is fine for FM, where there are no amplitude variations, but it will only cause tremendous distortion to AM where amplitude varies.

One way to make voices on SSB sound better is to slow down the transmission speed. Before a QSO, record everything you want to say on tape at 15 IPS. Play it back on the air at 7½ IPS. Have the fellow at the other end record at 7½, then play back at 15. He will find the frequency response to be almost twice as good. We used the same bandwidth at a lower speed.

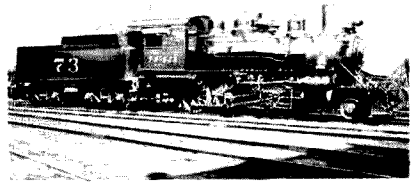
There seems to be quite a bit of confusion about amplitude modulation (which SSB is). A couple of months ago, Wayne wrote, "How come if you vary the level of the carrier, the carrier doesn't change level," or some such thing about AM. I have almost completed an article that explains all this with a little trig and algebra. Also, I explain the phasing method of generating SSB and the advantages of AM. Yes, AM does have some advantages (redundancy strikes again), but we must use a different detector to take advantage of them. Is 73 interested?

Harold Hallikainen WA6FDN/6
San Luis CA

I don't work 220 yet, but it burns me up that anyone would ever think of giving more privileges to the CBers. Amateurs have to work to get a license, take a test, and keep a log. Why does the FCC push us around?

All a person has to do to be a CBer is fill out a paper. When he signs his name, he can use the band for anything he wants. Excessive power, foul language and illegal antennas – he can violate any rule he wants and the FCC doesn't say much. But, if an amateur violates a small rule, his license is revoked or he is fined.

I think the FCC should crack down on CBers and stay off our backs!



By the way, I think 73 magazine is the best magazine for me! I really enjoyed "Step on the Klutz" by Bob Manning.

Al Wilson WN8LUD
Riverview MI

What really pushed me over the hump to subscribe to 73 was Bob Manning's article in the June issue. Perhaps mine, as well as other ham's subscription, will replace the one that Carl Emerson cancelled.

Thank you and keep up the good articles that are of a general nature and of assistance to the Novice as well as the 2 meter fans.

M. June Zenge WL7HKA
Ketchikan AL

Just thought you would get a charge out of this. Like you said, you never know where 73 will pop up next. This shot was taken in 7-46 at the Frisco Roundhouse in Memphis TN. The engine was built in 1912 and scrapped about 1950. So I hope you're around that long.

Don Wirth WBØECM
Maplewood MO

Could it be that your periodic mumblings about getting out of the business, retiring to other pursuits, etc. have had repercussions in south Georgia?

This photo is of the sign erected at the base of a fire lookout tower located on busy US 301 in Wayne County, Georgia, about 50 miles north of the Florida border.

Read and heed!

M. Wayne Street, Jr. K4QEX
Savannah GA

Great cover on June issue. Let's see more.

Richard Rosenbaum WA2AOI
Jamaica NY

I'm very interested in ham radio and enjoy your magazine.

I m writing concerning the article "OSCAR MARINER on MARS" published in the May issue, in which I understood that there was a manned spaceflight to Mars. Has there really been such a flight? Or, was this article some idiot's idea of fiction?

MORE LETTERS

I am interested in factual information on all phases of radio communication and if this was the author's idea of a joke, then 73 has no place on my bookshelf; it will be 73 to 73 with no 88.

Hilda Dip Chan
New York NY

I have tried all the ham magazines and 73 is still the best all-round publication. Some are all news, some are for geniuses, and some are UGH! half CB. Almost all of the articles in 73 are within my meager knowledge. I am a hard core appliance operator.

My favorite series was the General Class Study Guide. I really enjoy the articles written by fellow hams and I hope they will continue.

Thomas Grabowski K3SPY
APO San Francisco

In answer to your card asking for a renewal on my subscription, I would like to state that I am not renewing this year. I have nothing but complimentary things to say about the magazine and I am sure that it fills a need for many amateurs. However, since I am not in the least interested in RTTY, SSTV or the higher frequencies, I am left with little of interest other than the editor's tiffs with CQ.

Roger W. DeBusk M.D.
K8LSG

I enjoyed solid state construction and Bob Manning's articles are very very good – really enjoy them.

Keep plugging away for us as your efforts are greatly appreciated.

Jack L. Zimmerle WB4QXI
Huntsville AL

You might want to mention in your excellent publication that copies of a U.S. Air Force Medical Service Digest article on Navassa Island activity in February, 1971 are available free of charge by writing to: Richard J. Brown WØEXD/KC4, Pathology, Bld. 626A, NAMRL, Pensacola FL 32512.

Would you like to know why I decided to subscribe to 73? Well, in addition to the articles and ads, both interesting enough, it was the letter by P.T. Atkins, WB2OZW in the March issue. It was the hope that ham radio can have that quality and lead to those kinds of contacts that got me into the business in the first place, which has been confirmed by some great moments within the limited opportunities of the Novice privileges, and which makes me determined to get that General! So, I concluded that 73 would also be of some help to that end.

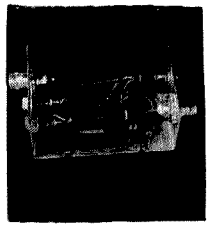
David A Fee WNØEWE
Brookings SD

I think your magazine is the best. Since you reach a lot of people, maybe one of them can help solve my problem. I've exhausted all the amateurs in this area.

I have a 1969 Chevrolet custom camper with a 396 engine; 18,000 miles on it. In 16,000 miles, I have burned up 6 sets of points and 3 sets of plugs. Even that isn't so bad. The real problem is how to get rid of the S7 level engine noise.

Hope someone can help me.

Keep up the good work.



Roy R. Edmiston WA7LUX
Henderson NV

I read about Al Smith (W1GAA) and his problem concerning pirates in the ham business in the June Letters column. I have had a couple of similar experiences and the Post Office handled them with excellent success. In fact, it surprised me. All you have to do is go to your local Post Office claim office with bona fide evidence (cancelled check) and a copy of the order or any correspondence. Tell them all about it and I'm sure action will be forthcoming. No attorney fee either. Hope this is some help in getting your hundred bucks back.

Guy C. Long K9DOF
Elkhart IN

I built the VHF Scaler described in the June 1972, 73 and thought you might be interested in the final construction.

The two photos show the layout in detail. I eliminated the divide-by-100 IC. The unit is powered by a lantern battery. I have already pointed out an error on the bias resistor that was shown as .18k (properly 180 ohms). Incidentally, I have yet to hear from the author on the subject. It would seem that the author should be required to answer and answer promptly; who else can the constructor turn to for answers. If there is any further interest, please feel free to contact me.

Joseph F. Dineen W1JSS
Westwood MA

The idea that you brought out in your recent editorial "Going Through Channels" is really worth a lot of thought and a trial.

A similar idea that may also be worth study and a trial would be to use specific frequencies or channels in each of the high frequency bands for tune-ups. This could decrease the QRM throughout the band by concentrating that form of interference at specific spots. These could be, for instance, in the 7 MHz at 7050, 7225, and 7275. The idea would be to use a standard frequency for this purpose and have enough of them through the band so that the transmitters would still be in tune when the operator goes over to his operating frequency.

This would be similar to the procedure that's used on some nets of having everyone tune-up on net frequency at a specific time just before roll call. This net tune-up, of course, would not apply to an all day net like ECARS. That net operates much more effectively if people tune-up on another frequency; yet, when they do so they are likely to tune-up on someone else.

One idea that fascinates me is operating cross band between two meters and ECARS on 40 meters. It seems to me that it would be fascinating to check in and monitor ECARS on 2 meter mobile.

I enjoy your editorials and your magazine. I think it is the best of the bunch. The other magazines are good, but you are to be commended for being more progressive and innovative. In these times of change we need a magazine such as yours with an editorial staff that is adaptable to the new circumstances of the day.

Keep up the good work.

C. W. Tazewell W4NGU/3
Baltimore MD

On page 34 in the May issue is a mistake which has appeared in your magazine at least 100 times. (This is not much of an exaggeration.) Examine Fig. 5. When you use half of a center-tapped transformer you do NOT obtain one-half of the impedance! For gosh sakes, folks, I cannot understand how a magazine sophisticated enough to include many complicated IC projects can constantly fail to catch this silly, stupid error. It's usually in at least every other issue! Stop it! By perpetuation of this you are doing the industry harm.

Clyde Wade
Little Rock AR

Look here Clyde, you know and we know that halving the winding does not halve the impedance, but since it stands to reason that it should why make waves? Don't be a trouble maker all your life. Besides, this is the only thing that one hundred different 73 authors ever agreed on, so why try to spoil it?

BETTER THAN POT!

Being a college student means I have to give up many things (like sleeping at night, which I probably wouldn't do anyway). However, at the risk of not eating for the next week or two, I have to renew my subscription to 73 (besides I wouldn't want the staff to starve). At any rate, I would completely lose my mind if I couldn't read 73 every month. I have to have at

Caveat Emptor?

Price – $2 per 25 words for non-commercial ads; $10 per 25 words for business ventures. No display ads or agency discount. Include your check with order.

Deadline for ads is the 1st of the month two months prior to publication. For example: January 1st is the deadline for the March issue which will be mailed on the 10th of February.

Type copy. Phrase and punctuate exactly as you wish it to appear. No all-capital ads.

We will be the judge of suitability of ads. Our responsibility for errors extends only to printing a correct ad in a later issue.

For $1 extra we can maintain a reply box for you.

We cannot check into each advertiser, so Caveat Emptor . . .

START PACKING! Plane or R.R. tickets, road maps. Got 'em? Then you're ready to take off for the gala ARRL Hudson Division Convention, Oct. 21–22, Hilton Motor Inn, Tarrytown, NY. Plenty of free parking. Exhibits, 2 meter FM, RTTY, lectures, contests, YL-XYL events, gabfests, N.Y. sightseeing, prominent banquet speaker. All ya' need to know from Dave Popkin, WA2CCF, 303 Tenafly Road, Englewood NJ 07631. Free gifts for early registration.

SSTV, RTTY, WWV, tone to logic decoder projects. Chassis, plans, hardware, eight 2¼" x 3" epoxy cards, $6. Hornung, 1630 Bowling Lane, San Jose CA 95118.

GALAXY V, MARK III w/VFO, ac/dc supplies, an $800 package – first $400 gets it ppd. K3TUF, Phil Theis, 3050 Hempland Rd., Lancaster PA 17601.

CINCY STAG HAMFEST The 35th Annual STAG Hamfest will be held on Sunday, September 24, 1972 at the ALL NEW Stricker's Grove, on State Route 128, one mile west of Ross (Venice) Ohio. Check local area map for new location. Door prizes each hour, raffle, lots of food, flea market, model aircraft flying, and contests. Identify Mr. Hamfest and win prize. $5.00 cost covers everything. For further info. contact: John Bruning, W8DSR, 6307 Fairhurst Avenue, Cincinnati OH 45213.

WANTED: Old 3D comic book and viewing glasses. Dave Ingram, K4TWJ, Eastwood Village #50 No., Rt. 11, Box 499, Birmingham AL 35210.

WANT OLD RADIO TRANSCRIPTION DISCS. Any size or speed. Send list and details to Larry Kiner, W7FIZ, 7554 132nd Ave. N.E., Kirkland WA 98033.

SELL: Measurements Corp. Model 760 Standard Freq. Meter; Range 25–50 MHz, 150–175 MHz, 450–475 MHz. Accuracy .0004% @25 MHz, .00002% @450 MHz; .00007% @150 MHz. Excel. condx. w/manual. $395. plus shipping. K2LIU, RD #3 Freehold NJ 07728.

WANTED – Collins 75A2 in mint condition, complete with mechanical filters State best price first letter. Write W4TVZ 339 W. Dixson Ave., Orange City FL 32763.

EXPERIMENTERS Make etched dual in-line printed circuit patterns on your board at home. Quick! Easy! Inexpensive! No taping! Details: STAMP-A-CIRCUIT, Box 113S, Westchester OH 45069.

SLOW SCAN goodies for sale 'scope adapter (June 70 QST) $20. Variable 500 to 6 kv supply $10. 5AMP11 scanner CRT $7. 6217 super photomultiplier tube $3. 5UP1 CRT $4. 55875 Slow Scan Plumbicon w/info $20. Dave Ingram, K4TWJ, Eastwood Village #50 No., Rt. 11, Box 499, Birmingham AL 35210.

TOWERS protected, stops rust 3 years. Zinc galvanize equals hot dip! 16 oz. spray can $3.95. Protect rotors etc. 2 years with wax base rust inhibitor lubricant. 7 oz. can $1.89. Postpaid. HTP, Box 901, Cupertion CA 95014.

VHF NOISE BLANKER. Models available for VHF transceiver and receiver-converter systems. See advertisement in July issue 73. WESTCOM ENGINEERING Box 1020, Escondido CA 92025.

YOUR CALL LETTERS Two sets, for windshield and rear glass. Smart white letter with red outline. Easily installed pressure sensitive decals. $1.00 postage paid, anywhere. Satisfaction guaranteed. Lake Jordan Artists, Slapout AL 36092.

FM IC-20 & REGENCY-2A owners, Now Available, 4 frequency tone burst oscillator, internally mounted. $29.50. Bob Brunkow 15112 S.E. 44th Bellevue WA 98006. Phone (206) 747-8421.

TECH MANUALS $6.50 each: R-220/URR, R-388/URR, R-389/URR, R-390/URR, R-390A/URR, URM-25D, TS-148/UP, TS-403/U, OS-8C/U, TT-63A/FGC CV-591A/URR, TT-98/FG, TT-100B/FG, UPM-45. W3IHD, 4905 Roanne Drive, Washington, DC 20021.

SELL OR TRADE: Ten Tech PM1, never used, 25 feet heavy duty AC cable, bag used tubes, three TV transformers and USN power supply, S-85 receiver with Q-multiplier. WANT: Johnson Transmatch or equivalent (200 watt minimum), 4:1 balun, and SWR bridge. John Tourtellott, 50 Johnson Avenue, Ridgway PA 15853.

TELETYPE 28ASR Excellent condition. 6 manuals. TT/L-2 TU. $1,100 for lot. Pick-up only. Henry Rainville 106 S. Cornwall Ave. Ventnor NJ 08406, (609) 822-0098.

HAMFEST IN MEMPHIS September 17, State Technical Institute, Interstate 40, east of city. Prizes, flea market, tech talks, MARS meeting, XYL activities, food. 8:00 AM to 5:00 PM. Talk in on 2m .34–.94, .22–.76, 75m, 3.980. Write Evin, WB4VDH, 239 Kenilworth, Memphis TN 38112.

NATIONAL AMATEUR CRYSTAL BANK A central receiving, testing and matching service for exchanging 2 meter FM crystals. Send SASE for details. National Amateur Crystal Bank, Dept. 73, P.O. Box One, Wykagyl Station, New Rochelle NY 10804.

...AND MORE!

least one vice or addiction (it's the IN thing).

I really enjoy your magazine if you haven't guessed that yet. Please keep up the good articles and circuits, especially the circuits since as a physics major I can appropriate the needed parts from the electronic's lab. (They pay me once in a while for working there; not enough – but, there are advantages like good test equipment.)

You're doing a fine job. Keep up the good work.

Kent Croynn

Here is my payment for a subscription. I recently picked up one of your magazines and was surprised at the improvements that you have made. The articles are very up-to-date with FM and state-of-the-art techniques. You stay with the current trends and I'll stay with 73.

David Parker WB4GLO
Grand Farks AFB

All I can say about seeing the K1YSD article in the June issue is that, whenever I open that issue, my eyes are mysteriously drawn to his article where I'm then transformed into a crazed maniac suffering from laughing convulsions. When my friend reads the article, the same thing happens to him. It must be a disease.

Bob Davidson WB8IPR
Chagrin Falls OH

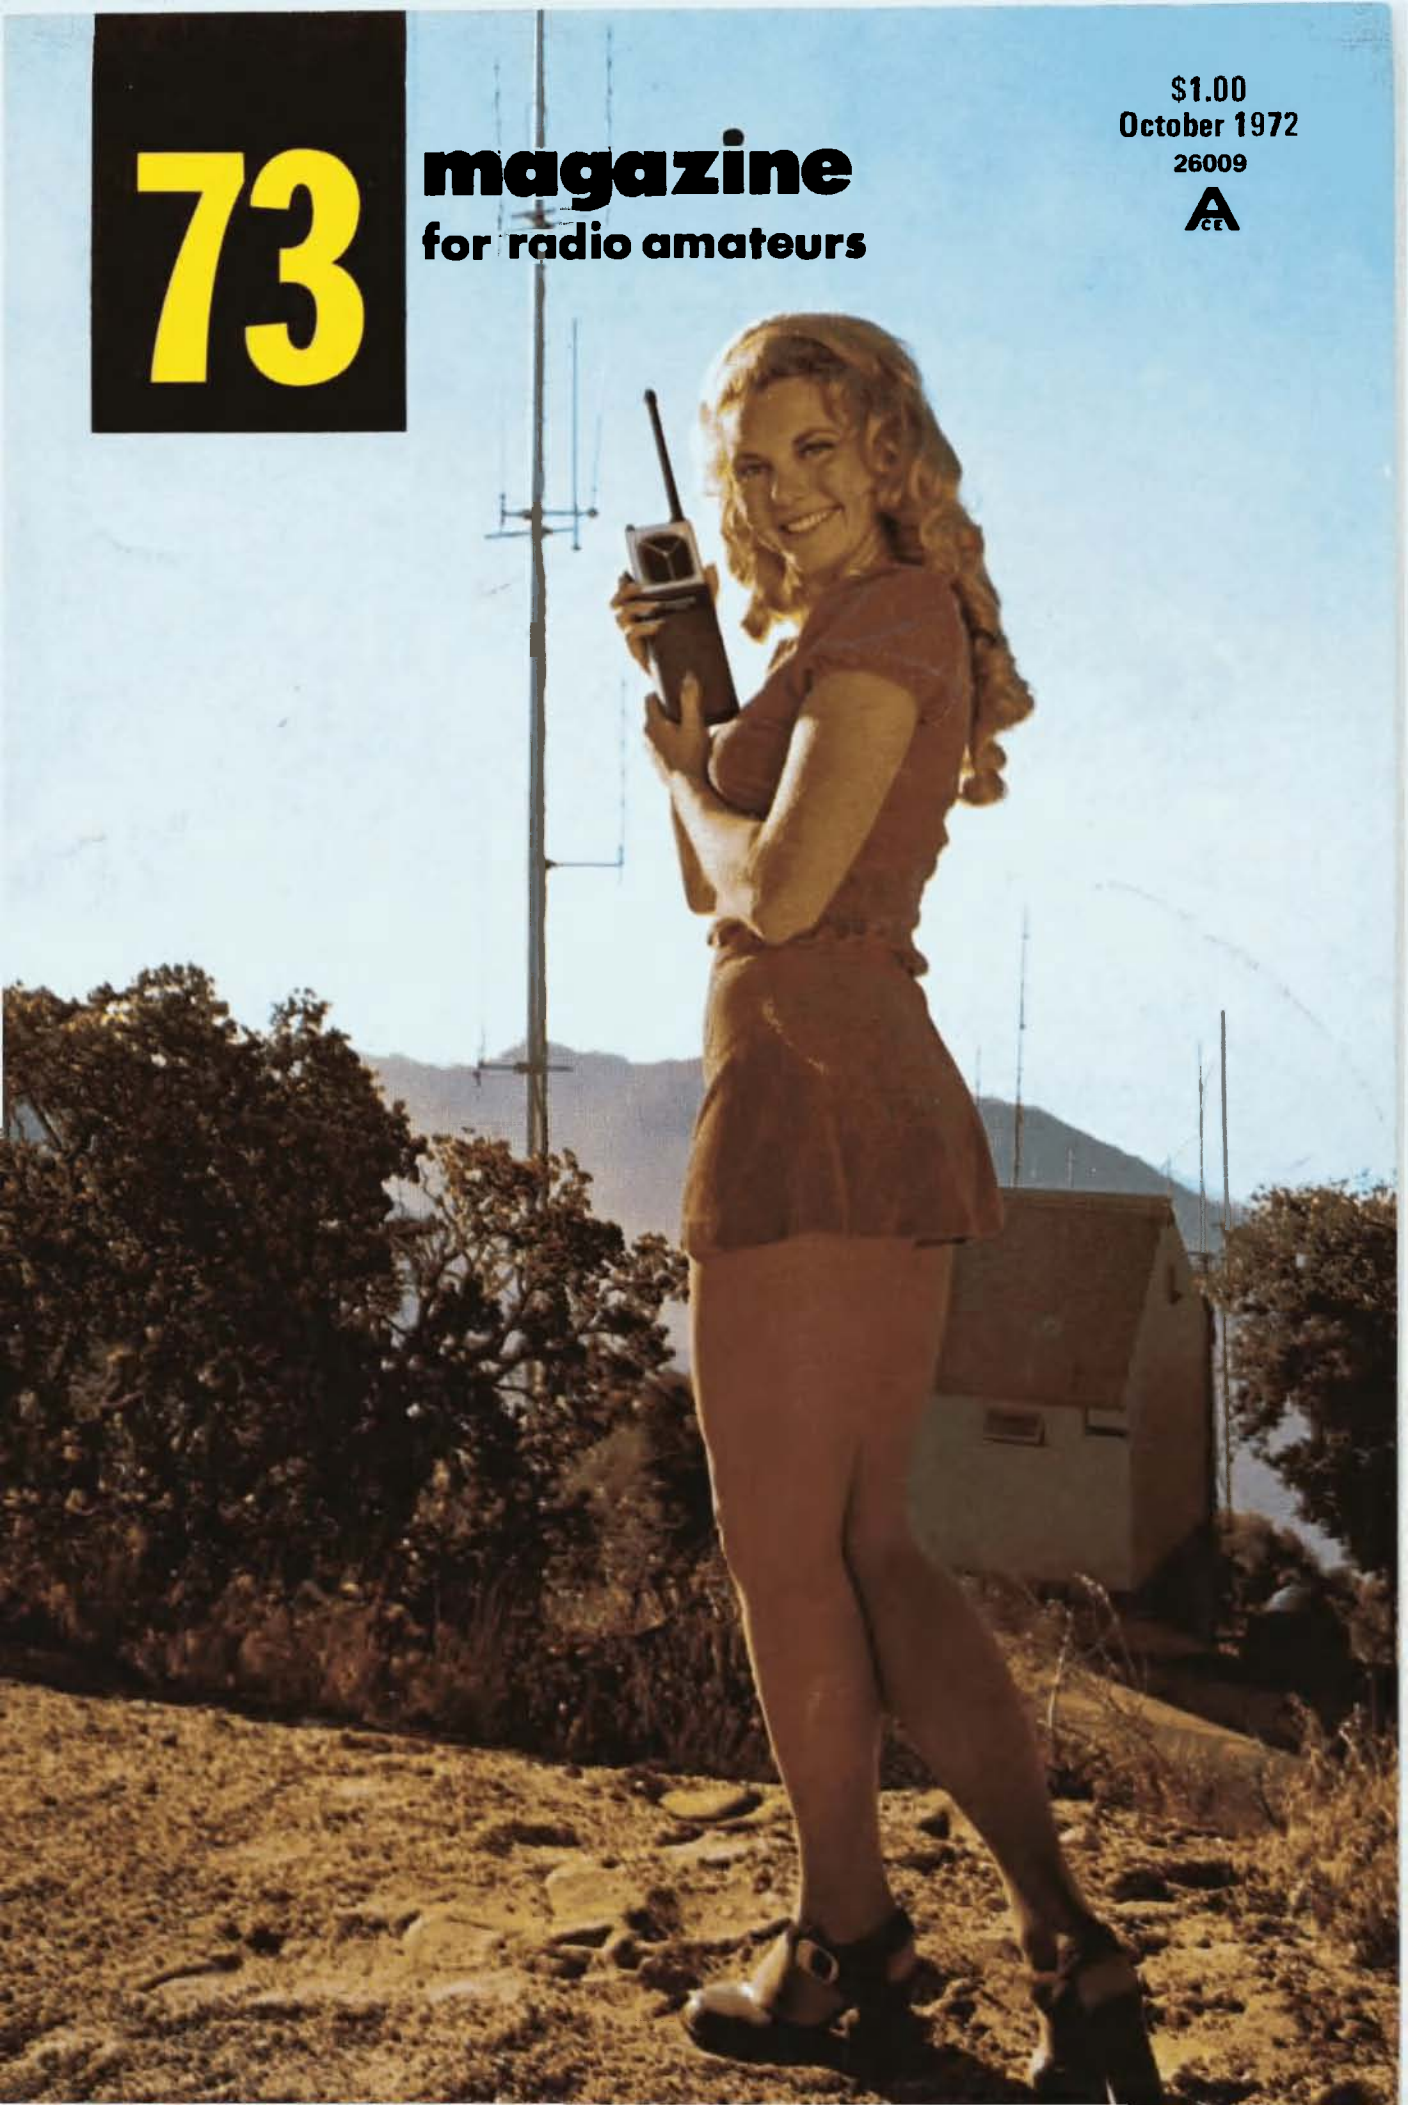
A few weeks ago while we were in Chicago for Expo-72 Wayne and I had a chance to work through a very fine repeater. The Chicago 16–76, WA9ORC. The repeater features several satellite receivers with a "voting system." I must say, I was impressed with WA9ORC. At the Expo-72 site the ORC gang had a control point set up for talk in and message handling. They had several of their people walking around the vast area with walkie-talkies on a "secret frequency." These people were acting as security for the area. As will unfortunately happen with all the gear on display at a convention, a couple of units were "ripped off." It didn't take long for the ORC cops to get into action. As an example, Wayne and I thought one of our Standard walkies had been stolen. While Wayne reported the possible theft I went out to the car to check on the possibility that we had already packed the unit (which we had). On my way back to the Exhibit I was stopped several times by ORC cops asking to see my Standard. In all, the Expo-72 show was a lot of fun. I understand it was much better than last year. The exhibits were interesting, as were the talks and the Flea Markets. The Flea Markets were my favorite. For a couple of acres all you could see were hams selling their wares. No matter what small part or large piece of gear you were looking for, it could be found. I'd like to say to the Expo-72 group, Well Done.



A small problem has developed with the Bajo Nuevo DXpedition. Instead of going to Bajo Nuevo we may go to Serrana Bank, unless some problems with the Colombian Government can be ironed out. I had written to the official amateur organization of Colombia, the LCRA. They sent back their new criteria for a DXpedition to Bajo Nuevo. They are: 1) The expedition leader or Director must be a Colombian citizen; 2) The Director must have a Colombian license; 3) 50% of the expedition members must be Colombian citizens; 4) The expedition must be sponsored by the LCRA. I am told by a member of the last DXpedition to Bajo Nuevo that this action is the result of one Colombian gentleman and it was done for personal reasons. The new criteria virtually makes a DXpedition to Bajo Nuevo impossible. However, there is one more avenue of attack I am taking. We are still planning on Bajo Nuevo but if the problems can not be resolved we will go to Serrana Bank which is not far from Bajo. Serrana Bank will be just as good a DXpedition. I have already received the call KS4BS for Serrana Bank. Either place, the DXpedition will take place. I still need written confirmation from some of you who want to go on the DXpedition. If we do indeed go to Serrana Bank we will have room for a couple more operators. Today, those of you who want to go on the 73 DXpedition who have not written, please do it. If you wish, give me a collect telephone call. We need to start getting the equipment checked out and ready to go. There are a million details to be worked on if we are to have a good DXpedition so please write or call today.

What do you do when you find yourself operating out of band? I would think the normal procedure would be to quietly sneak back in without saying anything. Perhaps no one will notice. This might work if you are a few cycles out of the band. But, what do you do if you are engaged in a roundtable with 5 other stations and you find yourself 10 kHz

EDITORIAL BY WAYNE GREEN

Robot Surprise!

The announcement in the September issue of 73 of the Robot plan to sell direct from the factory and thus make it possible to cut the price of their slow scan units to $295 each for the camera and monitor should keep them busier than a skin diver in a bunch of jellyfish keeping up with orders.

That new price tag should help a lot of fellows make the decision to go slow. And don't forget that you don't have to get that camera right off either. You can make do perfectly with a little cassette tape recorder with a tape made up from any neighboring camera.

Hams Don't Build?

The other day an article came in, written by an old timer, complaining that amateurs don't build any more. In the old days the amateurs used to build everything, now they all go out and buy their rigs and just operate them like appliances . . . etc.

This old timer meant well, but he sure was uninformed. I don't doubt that most of the fellows he talks with buy instead of building. The chaps in his club probably do the same. The fact is that not very many old timers do build.

But the newer amateurs are building gear like never before in the hobby.

Now, is Green telling it like it is or is he exaggerating? Who is right? The fact is that you can check for yourself and get the answer in a couple of minutes. Please just thumb through the last sixteen pages or so of this issue and see just how many pages of ads there are for parts. Now, grab the first old timer you see and get him to break out a 30's copy of QST and count the number of pages of parts advertising. There is no comparison whatever. I rest my case. If parts weren't selling and selling like crazy you know darned well that all those companies wouldn't be in there advertising them.

The old timer does not build. With but few exceptions the older amateurs are tube men in the day of the transistor. All they know how to build are tube sets and who would bother to build them today? With the exception of Bill Hoisington and Frank Jones, how many of the old experimenters have been able to convert to solid state?

Our technology has been escalating rapidly. Twelve years ago when we started 73 we had a few transistor circuits – mostly audio amplifiers and code oscillators. The nuvistor was the big news in 1960, if you remember. By 1965 tubes were in the minority and virtually all articles were on transistorized construction. Now transistors are about gone by and we are dealing with integrated circuits most of the time.

Counters which boggled the mind a few years ago now are on one little board. We have the GLB frequency synthesizer on a small circuit board – a complete unit on a tiny board that would have taken a couple relay racks of tubes just a few years ago. More and more ham shacks are now using the digital clocks – clocks that were restricted to laboratories and large computer installations not long ago.

Tubes – transistors – ICs – what's next? Something will come next, of course.

Looking at the latest all IC VHF receiver built by Bill Hoisington, I rejected the article on how hams don't build any more.

Invitation to Steal

Most amateurs are pretty good eggs. Some are rotten. Add to that mix a few "listeners" who can be either and you have a few people monitoring the bands who might be up to no good.

The fact is that there have been several incidents where things went all wrong after an amateur mentioned over the air that he was going to be away from home. The worst case reported was where the amateur mentioned over a repeater in New York that he would be away for the day on a business trip. He arrived home to find his home had been ransacked and his wife raped.

There is a good deal to be said about prudence. Remember that even FM receivers are sold to anyone and everyone. Those little VHF monitors which get the weather and police will also bring in your local repeater – and you – and they could bring unwelcome guests.

FAT NOVEMBER ISSUE

There are a few more ads in this issue of 73 than we expected, so it is a little more packed than we like. This is one of the problems with last minute ads – by the time they come in, unannounced, we have already laid out the articles and have them in negative form ready to print and it is too late to change them.

If the ads keep coming in for November the way they have started, this could be the biggest issue we've ever published. We'll see. We have some corking good articles being readied for this special issue – a whole lot of them. Imagine a magazine as fat or fatter than QST, but with articles instead of operating news, contest results, RACES, IARU, and all that!

And say, if you have any articles in mind which might be of interest for a special FM issue – a surplus issue – an antenna issue – a mobile issue – a CW issue – a VHF issue, then get to your typewriter and get started. We're hard at work right now on these special issues for 1973.

FM DEVELOPMENTS

Old timers are coming on the FM repeaters in droves all over the country. No wonder, of course, since the word has been spreading that here, for the first time in years, is a way to get on the air and have contacts without interference.

Mobile on the lower bands was fun – kind of – if you didn't mind always being the low man, getting stepped on by higher powered stations, losing contacts, and extremely fragmented conversations. About the only gripe on FM is that a few of the repeaters are so busy that rag chewing gets discouraged during the busier hours – but then there are always repeaters that are not being used and which will welcome all but the fustiest of old timers.

The Repeater Bulletin is doing very well, by the way. This is a little publication put out by 73 for the repeater users in the northeastern part of the country. The August issue ran to 48 pages (Radio Electronics size magazine), partly due to the amount of material submitted by the readers and partly due to Wayne Green writing at length. The cover picture of Judi Repeater turned everyone on so much they didn't notice she was talking into the back of her microphone. Shades of Playboy! The most startling announcement in the Bulletin had to do with limiting the circulation to amateurs of high moral turpitude. This far-reaching decision obviously would tend to limit the circulation in certain areas of Connecticut.

Not a little space was devoted to news of the Northeast Repeater

Association, which coverage elicited angry letters and even legal threats of suits and attachment from some of the principles. I really must be careful or I am liable to damage my hard-earned reputation for being non-controversial.

The FCC still is sitting on the promised repeater regulations, and a good thing it is. Virtually none of the problems that they were developed to cure have turned out to be worthy of rule changes, so the whole docket was an exercise in wasted time. Repeaters have not spread out and encroached on AM frequencies and legislation to prevent it is totally unneeded. The fact is that the service provided by repeaters has been so fantastic that there are only a few AMers left on two meters, most of them having long since gone FM, and the emerging problem is how to put the old AM parts of the band to use to keep Citizens Band manufacturers from getting the EIA to try and liberate 144 MHZ for the Ten-Roger masses.

Repeaters have not linked up in long strings either and rules to prevent it would be little short of disastrous at this time. Every time a rule like that comes along today it shoots down a hundred possible future developments that weren't even thought of at the time of the rule. Let's stop this mania for regulation and consider new rules only when things really get out of hand.

The Los Angeles FMers are getting together at last to work out their problems. Hooray! If more of them could pay a visit to New England they would get a good view of what FM and repeaters could be when managed well. New England has turned out to be a model for the whole country on how great FM can be developed. About 70 repeaters are serving over 5000 active FMers and serving them extraordinarily well. Some repeaters have as many as 400 users – others maybe only twenty or so.

Most of the standard thirteen FM channels are active from New York right on up through Boston. If you have a 13–73 crystal pair you can work WA2SUR in Manhattan, WA1KHC in Massachusetts and WA1KGP in Maine. On 04–64 you start out with K2LJC on Long Island, go to WA1KHA in CT, and WA1KGS in Boston. On 25–85 you have WA2PDJ on Long Island, WA1KGY in CT, and K1MNS in Derry NH. Ditto on 37–97, 34–94, 28–88, 22–82, 19–79, etc.

The 220 MHz band is being repeaterized rapidly in an effort to spike the EIA drive to steal the band from us. There are about ten active 220 MHz repeaters in New England and more popping up around the country every week. Clegg and Tempo are building gear as fast as they can. Wait'll you see the Tempo 220 rig in the November 73.

The 73 Tour

We wondered why it was taking so long to get an okay from the Russian tourist agency Intourist confirming the 73 tour accommodations. Finally word came through that there were no rooms available in Moscow. Okay, how about Leningrad or some other city? No, came back the immediate reply, all hotels are filled up. Translation: they don't want USSR amateurs to meet and talk with US amateurs. The group decided to make it Madrid instead of Moscow.

Although the group is still in flux, it now appears that there will be aroud 20–25 going on the trip. It should be a blast – and frankly, a lot of us will be much more comfortable not going to Russia. Few tourists coming out of there say much to encourage others to go. Who wants to be watched and spied on with suspicion while visiting a country – to know that befriending a local amateur might jeopardize his future – to know that other visitors have landed in jail for years through no fault of their own and in spite of everying the U.S. could do. Who needs it?

DISASTROUS DISASTERS

The floods this summer exposed the weakness of our emergency communications. In Pennsylvania all existing communication systems fell apart. Civil Defense was set up in cellars in preparation for bombs and they immediately flooded out. Police and other short haul systems were useless. CB operators tried to help, but lacked any organization or experience and more often than not were a waste of time.

The fact was that, as in most other serious emergencies, the responsibility fell on amateur radio – and amateur radio was ill prepared for the responsibility. They needed short, medium and long-haul communications – which amateur radio is ideal for. Most of all they needed someone in charge . . . this is where things fell apart. Orders were conflicting – great things happened – terrible things happened.

One of the most valuable communications systems set up for the emergency was a two meter FM repeater. Food, shelter, clothing, health and welfare messages, the works, were routed through this repeater. And would you believe that while tens of thousands of people were depending on this there was an amateur in a responsible position in Massachusetts trying his best to keep FM amateurs from driving to Pennsylvania to help?

The Clegg company helped a lot by providing a dozen FM transceivers. These were picked up and flown out by helicopter on the same day that the above mentioned Massachusetts amateur was talking people into not going to help because he heard from a friend that there really was no emergency. . . .Wayne

AMSAT NEWS

Michael Frye WB8LBP
640 Deauville Dr.
Dayton OH 45429

I have been recently informed that A-O-C will again be delayed until November and possibly into early December. This is again due to NASA scheduling.

This column will be just a short rundown of recent happenings since all activities are progressing normally.

I strongly suggest that you at least monitor the AMSAT Nets as quite a lot of current information can be gathered there. If you have specific questions, check in and ask it, someone in the net will probably be able to help.

AMSAT members are working quickly to weld together a stable tracking network. And in my opinion they're doing a great job. Twelve definite command stations have been established around the world so that satellite monitoring will never be out of reach. NASA has graciously let AMSAT use their antennas at Goldstone California for tracking purposes. This will greatly increase reliability of communications.

If you want to work A-O-C the thing you should now be doing is setting up your antennas, and since this project will last through the winter, making sure they will withstand the extremes of your area. Transmitter and receiver operation should also be given a good check. Since A-O-C will accept any mode that appears in its passband maybe this should be looked into. Rumor has it that there is stiff competition going on between a number of groups to be the first to send Slow Scan TV through the satellite. Well I hope the best man wins.

. . .WB8LBP

NEW PRODUCTS

DX ENGINEERING CLIPPER

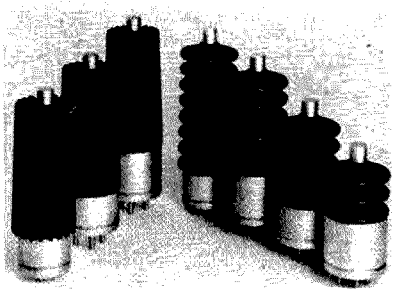
Quite a few schemes have been developed to increase the average power of the voice for sideband transmission, with the system used in the DX Engineering clipper being one of the more successful and popular.

The problem is that when you set the sideband transmitter to operate properly without splattering, the aver age power is quite low. Only the voice peaks fully modulate the transmitter. A clipper increases the average voice power, effectively increasing the transmitter output power. Indeed, when you check a station using such a clipper or compressor, you will usually see on the order of a full S-unit (6 dB) increase when the clipper is turned on.

Why doesn't everyone use one of these gadgets? Why aren't they built into all of the transmitters? They will be. The NCX-1000 has one built in, so does the Signal One. Unfortunately, the circuit is not at all simple and for reasons of economy it is left out of many rigs.

The DX Engineering clipper is designed to plug right into the transceiver. You unplug the first i-f tube from its socket, plug in the clipper, and replace the tube in the clipper. This adds the clipper to the circuit. The work is done at the sideband i-f intermediate frequency, with a 2.1 kHc mechanical filter built in to reduce the second and higher order harmonic which would otherwise cause miseries.

The clipper is transistorized, so it does not borrow enough power from the transceiver to upset anything. All in all, a clever device. The model presently available is designed specifically to work in the 32S1, 32S3 and KWM rigs. Cost $79.50 from *DX Engineering, 2455 Chico Ave., South El Monte CA 91733.*



LINEAR IF AMPLIFIERS

A new 4-page product bulletin (IFA-203) describes the expanded line of linear i-f amplifiers available from RHG Electronics Laboratory, Inc., manufacturers of microwave components, receivers and transmitters.

The bulletin contains information on the new line of Hybrid IC i-f amplifiers. In addition to the new products, the bulletin lists new features, improved specifications and reduced prices on many models. Scope photos, performance charts, and outline configuration drawings are shown along with comprehensive and informational technical text.

Bulletin IRA-203 can be obtained from: *Sales Manager, RHG Electronics Laboratory, Inc., 94 Milbar Boulevard, Farmingdale NY 11735. Telephone: 516-694-3100.*

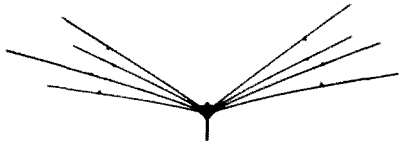
SEMTECH "TUBE-PAC"

"Tube-Pac" is Semtech's new line of silicon, high-voltage rectifiers intended as a direct plug-in replacement part for most popular mercury-vapor and vacuum glass tube-type rectifiers.

Designed to last the life of the equipment, Semtech's Stacks are smaller, corona free, dissipate heat more effectively and eliminate filament power. No special adapters are required to use Semtech's Stacks. For more information contact *Semtech Corporation, 652 Mitchell Road, Newbury Park CA.*

JUNIOR UHF CONNECTORS

When coaxial cable was invented, surely the thinkers of the day had in mind the ease with which rf energy could be coupled from one place to another. As originally planned, the rf coupled fine . . . but what about the coax itself? Was it *designed* to present the mechanical difficulties it does? Specifically, the problem is the copper braid. It sits there and dares you to try and unravel it. An awful job. The only practical solution is to do quick sloppy work and hide it all away inside some sort of connnector.



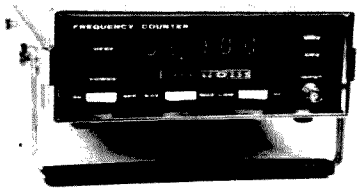
Coax connectors are an item all in themselves. They make coax a pleasure to use once they are installed, but you still have to connect the coax to the connector, etc. This means hasseling with the braid and hauling out the soldering iron. Compare your best effort to the drawings in the Handbook. Now you know why they use drawings instead of pictures!

Offering a partial solution to all this, L-COIL, an antenna manufacturer, has introduced a new line of solderless, no effort coax connectors. They are designed for RG58/59 coax and are compatible with the popular UHF series chassis connectors. To install one, all you do is trim the cable and screw everything together. The only tools needed are a pocket knife and a small pair of pliers. Since everything is held together by pressure, the tighter you screw it together – the stronger your connection will be.

Although most commercial equipment comes with UHF connectors, many hams like to use BNC connectors when they build a piece of gear. Part of the reason is that short interconnecting cables of RG58/U cable look sloppy and are clumsy to use when they have giant PL-259s hanging on each end. Also an amazing number of strange looking adapter cables must be made up to keep everything flexible. These new connectors are a chance to standardize. Use UHF connectors on all chassis, PL-259s on your large coax, and these little beasts on your small coax and interconnecting cables. They are small, light weight and look good.

L-COIL also markets two no-solder splices for RG58 or 59 coax. It's time to piece together all the odd lengths of scrap that's been collecting dust in the garage. According to the test graph supplied by L-COIL (actual test done at University of Michigan), you can end up with nearly virgin cable when using their splices. The graph shows variations of only about 2–3Ω impedance when 50Ω RG58 cable was connected with one of their splices. Their connectors' results were similar. For comparison, they tested two UHF connectors. These gave results of 33 and 37Ω. Send for the graph. *L-COIL Research, Brighton MI 48116.*

M² FOUR BANDER



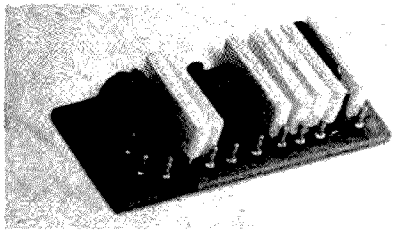
Here is a four band short antenna designed specially for marine use – up on top of the mast. It is a horizontally polarized antenna, a fact which may be appreciated by vertical antenna users. The lower angle of radiation does generally give quite an advantage over most verticals.

The M² is light – only about 15 pounds! – is made of stainless steel to

frustrate the sea breezes – and loads up nicely on 40m up through 10m. It is made up of four "cats whiskers" which stick out from the mast horizontally. Frankly we have no idea whatever why it works and the manufacturer is guarding the secret as "proprietary" information.

The specifications show that an SWR of almost 1:1 can be obtained with the M^2 on all four bands! Since the longest element is only about seven feet long, the antenna is a natural for shipboard use. For more info drop a line to *M^2 Electronics, 28627 Bridle Lane, Miraleste CA 90732.*

SPECTRONICS FREQUENCY COUNTER MODEL YC-305



A portable 5 Hz to 30 MHz frequency counter – is being introduced by Yaesu Musen, Ltd. (Tokyo), through the company's North American distributor, Spectronics Inc., Signal Hill, California.

The new counter, designated Model YC-305, features a dual-range system that provides 8-digit measurement with MHz or kHz indications. The unit will operate from a power source of 117V ac or 12V dc. Accuracy is ± time-base stability of 5 PPM ± one count.

Overall size is 8¾ by 3¼ x 10½ in. Weight is 8 lbs. The unit is warranteed for one year and is priced at $249.95.

Further information on the Yaesu Model YC-305 is available from *Spectronics, Inc., 1491 East 28th Street, Signal Hill CA 90806. Phone: 213-426-2593.*

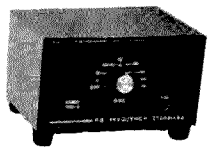
TWO FREQUENCY TONE SQUELCH

Alpha Electronic Services announces the smallest and most reliable two-frequency sub-audible tone encoder/decoder available for the FMer. The Alpha SS-80J dual tone, measuring 2-2/3" x 1" x 5/8" can now provide for many of the smaller mobile units and certain hand-held units two distinct tone frequencies for the purpose of controlling or selecting repeaters, base stations or mobile units.

Two frequency sub-audible tone operation makes possible the employment of multiple repeater systems, increasing the range capabilities of a communications system. The selective calling of two base stations, two groups of mobiles or special control functions are other capabilities of the two-frequency tone unit.

Contact *Alpha Electronic Services Inc., 8431 Monroe Avenue, Stanton CA 90680.*

STANDARD 146A

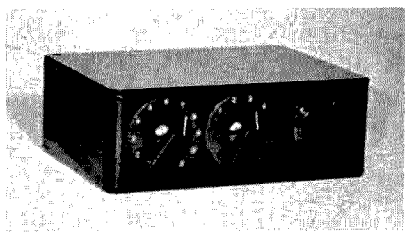


In fact the 146A is remarkably like the 146 hand transceiver. It has the same five channels, the same remarkably sensitive receiver, the same selectivity which keeps it from being clobbered when it is used near a transmitter – it still has that S-meter built in which doubles as a battery monitor – the jack to plug into your station antenna or mobile antenna so you can use the unit anywhere and take advantage of whatever antenna situation you have available – the remote microphone jack so you can wear the transceiver on your belt and use a hand mike – by the way, the regular Standard mike will plug into the 146A in case you have an 826 or other Standard model at home or in the car and want to use the same mike for both sets. There is a jack on the side so you can plug it into the car power while you are running mobile. The whole transceiver plugs into the Standard battery charger or you can easily pull out the battery and recharge it with any small power supply which will put out 50 mA.

The 146A comes with a telescoping antenna, but there is also available a short rubber whip (the rubber ducky) where you don't need as much signal and the shorter antenna is easier and safer to use.

The main difference between the 146 and 146A is that the new unit runs two watts output instead of only one – double the power out! Also there is room inside for an optional continuous tone unit for those of you who work through PL repeaters.

The features of the Standard 146 make it invaluable for many applications. It is by far the best selling hand unit in the country today according to all of the sales figures available. *Standard Communications Corp. P.O. Box 325, 639 North Marine Avenue, Wilmington CA 90744*



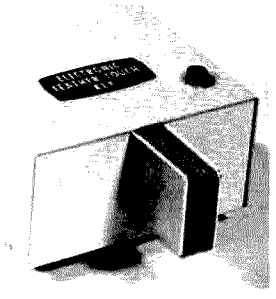
FM FREQUENCY STANDARD

This is a precision frequency standard that has been designed specifically for the FMer. For the first time you can be exact with your channel spacing and deviation. This deluxe standard provides precise markers for both receive and transmit channel spacing for all FM channels in the 10, 6, 2, and 1¼ MHz meter FM bands. An extremely fast rise-and-fall time square wave produces rich harmonics that are usable beyond 220 MHz.

Calibration of the Standard's precision 12 MHz crystal to the National Bureau of Standard's signal from WWV or WWVH is made possible by a simple adjustment provided through the front panel. Price is $44.50 from: *Data Engineering Inc., Box 1245, Springfield VA 22151.*

MODEL 48MV TOP BAND 160 METER ANTENNA TUNER

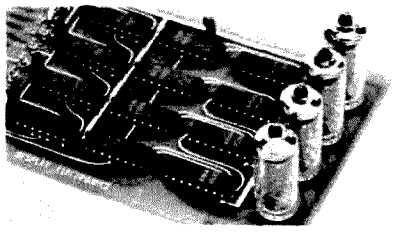
The FCC's recent initiative to raise power limits and expand frequency



privileges on 160 meters has given rise to a tremendous increase of interest in the Top Band.

A variety of commercial rigs on the market today provide facilities to operate 160 meters, but antenna requirements for the Top Band have always seemed to hinder those hams living in residential areas.

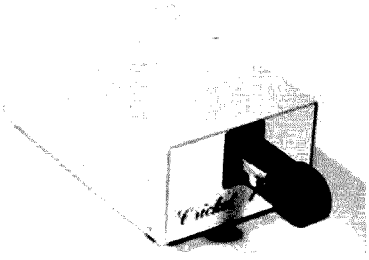
Now, with the development of Top Band Systems Model 48MV 160 Meter Matchverter, any ham having enough room for a 40 or 80 meter inverted vee/dipole can share in the thrill of working DX on the Top Band.



Top Band Systems offers immediate delivery for any quantity of 48MV Matchverters. Write for complete information on terms and delivery: *Top Band Systems, 5349 Abbeyfield Street, Long Beach CA 90815.*

ELECTRONIC FEATHER TOUCH KEY

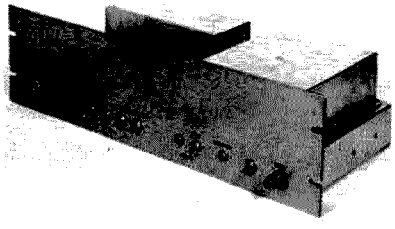
The Electronic Feather Touch Key is completely solid state. It requires no paddle movement, no spring tension or contact clearance adjustments and has no keying contacts. Keying problems caused by contact corrosion and bounce as well as paddle tension and movement adjustments are no longer a concern. The key is the natural interface for the extremely low current, high speed integrated circuits used in solid state electronic keyers. It sells for $22.95 (with remote spot P.B. switch). *Data Engineering Inc., Box 1245, Springfield VA 22151.*



NEW COUNTER AND DISPLAY MODULES AVAILABLE

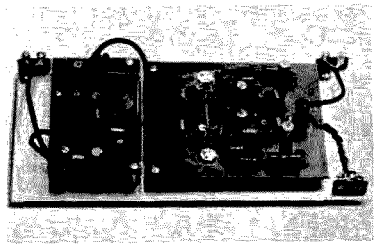
A new series of counter and display modules is available from Display Electronics. The CM Series modules include a decade counter, latch, decoder-driver, and readout for each digit. Standard modules are available with from 2 to 6 digits.

The price of a typical four digit module is $79.00 in single quantity. Delivery is from stock to 30 days. Custom designed modules are available on special order. Further information is available from: *Display Electronics, P.O. Box 1044, Littleton CO 80120.*



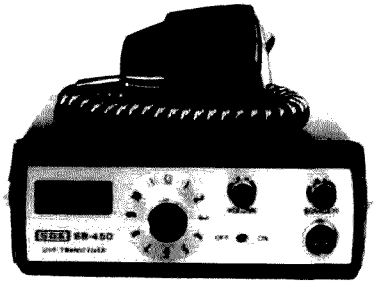
CRICKET 4 MORSE CODE KEYER

This popularly-priced keyer has more features for your dollar than any others in its price range.



A small solid state keyer designed for the beginner as well as the most advanced operator. It provides the user with fatigue-free sending and it's clean, crisp CW allows for easy copying at all speeds. $49.95 from *Data Engineering Inc., Box 1245, Springfield VA 22151.*

SC-ARPT-1 SOLID STATE REPEATER



The Standard SR-ARPT-1 is the latest in totally solid state repeaters for the land, mobile and amateur radio communications industry. Constructed to the most critical specifications for years of mountain top, trouble-free service, this unit will provide that extra edge of range needed for even difficult locations. Ready for immediate standard 19 inch rack mounting, the Standard repeater will fit in immediately to your existing communications network. Simply add 12 volts and connect your input and output antennas to the two antenna connections, add the proper crystals, and you are on the air with the finest in repeater communications equipment! Meets FCC type acceptance requirements for land, mobile and amateur radio service. This unit will ideally fit into your communications network and budget. *Standard Communications Corp., P.O. Box 325, 639 North Marine Avenue, Wilmington CA 90744.*

BROADBAND POWER AMPLIFIER KIT

Kit MP-100 is an all solid state broadband power amplifier covering the range of 0.5–100 MHz. Rated at 2.5W CW, it accepts inputs of AM, SSB, Pulse, and other complex modulation. It delivers full power output when driven by any signal or sweep source of 0.15V over the entire frequency range without tuning adjustments. The unit will not oscillate for any condition of load or source impedance and will withstand a 15 dB overdrive including short and open circuit loads. Of printed circuit board construction, the kit can be assembled in approximately 3 hours. A data and specification sheet is available from *Larkton Scientific, P.O. Box 302, Munroeville PA 15146.*

SBE 450 MHz TRANSCEIVER

Linear Systems has developed a new 450 MHz UHF transceiver designed for operation in the 420–450 MHz band. The book sized transceiver is the first SBE entry into the rapidly growing 450 MHz amateur band. The

MARS

Back on 16 February 1972, Wayne Green graciously agreed to allow space for these articles on MARS, beginning with the May, 1972 issue. The writer immediately attempted to contact the Chiefs of Air Force and Navy-Marine Corps MARS but met with little success. Due to more than twenty years membership in Army MARS, getting Army information is no problem but to say that I have met with small success in prying information from the other two services would be to understate the case! To be utterly candid, I have been met with silence. In spite of repeated phone calls and letters to those offices, requesting that I be placed on the mailing list of area bulletins, newsletters, etc., not one word has been received. Therefore I shall continue to concentrate on the information immediately available.

SB-450 comes equipped for operation with crystals for two of the twelve channels already installed. An attractive panel meter provides field strength information. For further information contact *Mr. David C. Thompson, Linear Systems, Inc., 220 Airport Boulevard, Watsonville CA 95076.*

SC-ATBE-1
TONE ENCODER

The SC-ATBE-1 tone burst encoder is a quality unit designed to compliment your Standard, or any other transceiver, for access to the various tone coded repeaters now in operation. It features the five most popular tones currently in use. These may be easily changed at any time for specialized applications. Superior stability employing quality mica capacitors. It comes complete with mounting hardware and connectors to make a neat, under the radio installation. For more information write: *Standard Communications Corp., Box 325, 639 North Marine Avenue, Wilmington CA 90744.*

One thing *was* learned – if you write Navy-Marine Corps MARS at the address shown in the May issue of *73* Magazine – Bailey's Crossroads, VA, your letter will be returned marked "MOVED, LEFT NO FORWARDING ADDRESS!" That address was taken from the current MARS brochure, distributed by the three services. This year, Navy MARS had the responsibility for mailing out Certificates of Merit after Armed Forces Day. Hallelujah! Navy-Marine Corps MARS is alive and well! The return address was right there on the manila envelope! It is: *Chief, Navy-Marine Corps MARS, 4401 Massachusetts Ave. N.W., Washington, D.C. 20390, Mail Stop 394.* Shortly thereafter a very nice letter was received from the Michigan Navy MARS Coordinator Clayton Dewey, giving the same address so it must be official!

One other correction, Army MARS member AA3FMH writes from Germany that it was A3NFX who won the First Army Commander's Trophy rather than A3NFS. The typographical error is regretted.

The deluge of letters from 73 readers concerning MARS membership is very gratifying. I have been slaving over a hot typewriter in all available spare time, answering mail and sending out MARS brochures. Why do I spend all this time and effort? Simply because it is a labor of love! When you become a MARS member, you quickly discover that it's not just another organization – it's a way of life!

Here's a suggestion – if you are in the eastern portion of the nation, listen to one of the fine Pennsylvania Army MARS Nets on 4025 kHz from 6:00 to 7:00 AM EST each morning; tune in the Southern New England Training Net on 4020 kHz at 8:00 AM EST; if you are interested in radio teletype, listen Saturdays on 4035 kHz at 2:00 PM EST. If you live in the central portion of the nation, Third U.S. Army has an area-wide net Monday through Friday from 1:00 to 5:00 PM EST on 7358 kHz – always a very busy frequency. Other Third Army nets begin at 5:00 PM EST on 4001.5, 4020, 4025 and 4030 kHz, on a schedule too complex to explain in this space – suffice to say you can always find two Third Army Nets in operation between 5:00 and 11:00 PM EST. These frequencies are shared with the other Army areas, and when one net is finished, another Army area starts its own operation. The same frequencies are utilized in Sixth Army area – so you can always find some activity!

Better yet – make your plans to attend the Tennessee Army MARS meeting, to be held in conjunction with the Memphis Hamfest on September 17. I will see you there and gladly discuss any MARS matter. For a MARS brochure or other information contact me at:

Harry Simpson A4SCF
73 Magazine MARS Editor
Peterborough NH 03458

HOT GEAR

Stolen early this year: 1) Home-built 2M rig built in a surplus .50 cal. ammo box. 1" diameter black meter with redrawn face in upper right corner; separate Xmit and Rcv oscillators, each with switchable channels. Built from components of RF-401 Series VHF Xcvrs. Has 13 internal nicad batteries. Box is brown except for aluminum plate on which oscillator switches are mounted. 2) Heath HW-100 Xcvr and AC power supply. Marks on top where a bracket was mounted. Also "WAØDAM Sooper Dooper Band Blaster" typed on Scotchtape above the S-meter. Information to Dave McFarland WA2JGP (ex-WAØDAM), 1074 Kenmore Avenue, Apt. 9, Buffalo NY 14216.

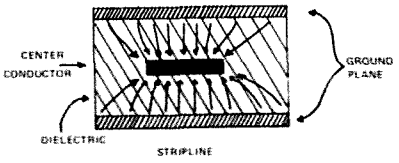
Microwaves

Amateur Microwave Question

WA600J: *"What is microstrip and stripline?*

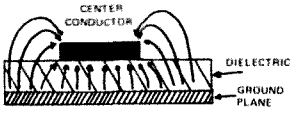
The answer to that question is reasonably simple. One day in the 1920's some enterprising amateurs took two different sizes of copper water pipe, cut some rubber supports, slid all three pieces together and, presto, the world's first coaxial transmission line. Later, manufacturers substituted woven braid for the outer copper pipe, polyethelyne for the rubber support, and solid center conductors for the inner copper pipe.

COAX



Then they sold millions of feet of this stuff by calling it "coax." We won't argue *why* electromagnetic waves propagate down this stuff, but we will note that the electric lines of force extend *from* the shield *to* the center conductor.

Later (in the '30s) some machinist with time on his hands made some big and small rectangular tubes and rectangular insulators, and, by fitting them together, made rectangular coax. By careful measurement, they found that almost all the electric force lines were crowded in the center, in the narrow gap between the center bar and the closest point on the outer tube (shield). This piece of information was duly noted and forgotten about, because all the engineers and scientists suddenly had their hands full with radar and WW II.

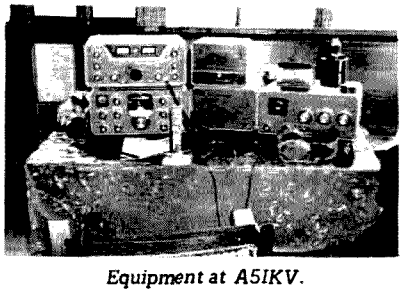


After this war, and the Korea thing, some mention was made of space travel. Now, scientists, engineers, and amateurs (e.g. "OSCAR") were all looking for a way to make microwave printed circuits. Someone remembered this rectangular thing and said this: suppose we make the rectangle thinner and longer, so that the ends have almost no effect on the electric lines. Then let's take away the end plates.

Let us then take two pices of double-clad p.c. board and etch our center conductor on one piece. Now, this "etched" side of the board makes our center conductor, the fiberglass or phenolic becomes the dielectric, and the copper "backing" becomes the outer conductor. This, they said, is a coaxial line in strip form, or strip-line. The impedance of the line could be varied by etching the line wide or narrow; the "sandwich" could be made small by choosing the dielectric as thin as desired. Several refinements have been made to this strip-line. Teflon® fiberglass was found to be one of the best dielectrics, and this board material is now commercially available. Impedance curves, filter design charts, and matching section curves were generated using this double-board approach to microwave circuit design.

STRIPLINE

Then along comes some crazy guy who wonders, what happens if you take away one of the ground planes? Will it still work? Fortunately for the world of science, yes, it will work, and it is called micro-strip.



Once again, design curves were generated to make microwave circuits on this type of construction. Then, as different dielectrics were tried, it became apparent that over a 10:1 reduction in circuit size was possible for some of the high dielectric ($E \approx 200$) titanium dioxide type of dielectrics. For some critical space applications, solid sapphire ($E = 9.5$) has been used as the dielectric.

In short, if you take round coax and make it rectangular, you stil have a transmission line. If you take away the side ground planes you have stripline transmission line. If you take away the top cover of strip transmission line, you have microstrip transmission line.

If you have any questions or comments about microwaves, drop me a line.

Equipment at A5IKV.

A5ITY, Radha XYL of A5IKV and A5IKV at Thimphu.

The above photos show the people involved and the equipment used in the operation of A5IKV, the DXpedition to Bhutan by Venkat, VI2KV.

Station YV-5-DZZ will grant a certificate to each amateur in each city and in each band for the first QSO contact with VY-5-DZZ or YV-5-DZY. YV-5-DZZ or VY-5-DZY can be worked every day on the following frequencies: 14,300 at 1100 to 1200 GMT, 21,252 at 1600 to 1700 GMT, and 14,150 at 2300 to 2400 GMT. Any amateur who desires this certificate should send a confirmed QSL and either $1.00 or 5 IRC to Francisco Reyes Viada, P.O. Box 517, Barquisimete, Venezuela.

* * *

VQ9FOS Amateur Radio Station will be operating from Mahe during the period Oct. 2–5, 1972 inclusive, as part of the Island's festivities.

Contacts will be offered on 10, 15 & 20 continuously throughout the period, and other bands by arrangement.

A Festival of Seychelles QSL card will be sent to all contacts and your return QSL card should be sent to: Hon. Secretary, Di. Cardell, VQ9DC, Amateur Radio Exhibition, P.O. Box 321, Mahe, Seychelles.

* * *

In response to an inquiry by Senator Goldwater, Chairman Burch of the FCC indicates concurrence with the view that there is minimal AM operation now on the 80 through 15 meter bands and that it might be a good idea to phase out AM by an amendment of the rules. This has been forseen as a forthcoming development by many influential amateurs for quite some time and everybody should be prepared to make their position known to their Directors if and when the commission comes out with a proposed rulemaking. There are potent arguments both pro and con on the subject and it is a step which should be taken without full consideration of every phase of the matter.

The real enjoyment of Slow Scan is being actively involved in both operating and building gear. This way you can add the little "goodies" you in particular desire, and possibly in the process stumble upon ideas to further the state of the art. Remember, Slow Scan is one field in which advancement can still be made on an individual amateur basis.

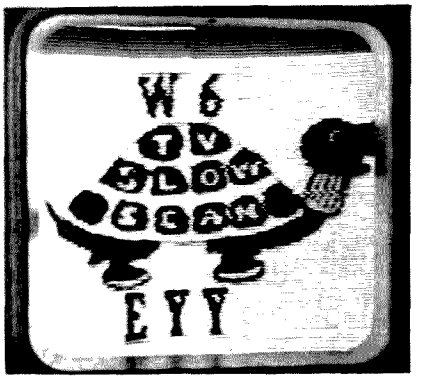
In the same manner spark gap paved the way for CW, and AM for SSB, Slow Scan may be the forerunner to communication facilities of the future. Ever heard of Holography? A three dimensional picture accomplished without lens. The Hologram is reproduced, presently, in a box. The viewer can look above, below and around the image. In fact, you can see as many angles of the object as the viewing windows of the box allows. One can conceivably visualize a system, for example, of color Slow Scan Holography analysis, transmission, and synthesis, where a heart bank in, say Chicago, analyzes a donated human heart and transmits a form of Hologram to, maybe a hospital in London, where an open heart surgery operation is in progress. The synthesized heart is reconstructed in free space (in the future) right above the patient so the surgeons have a guide they can look above, around, and under. The doctor in Chicago can display any sector at will, thus guiding the operation perfectly.

This is well within the realm of possibility and there are rumors of a way around the necessary monochromatic, coherent light (Laser beam) have been uncovered. Light emitting swept diodes? Special phosphor crt? Gee, the latter 1970's and the 1980's are going to be exciting. If slow scan research and communication technology advancements are your bag, check into ideas like Holography. Some companies, for example, like Edmund Scientific Co., 300 Edscorp Bldg, Barrington NJ 08007, have a full line of books and gear that are a "gold mine" for experimenters.

The slow scan directories are out and going like mad. If you haven't latched onto a copy yet, contact Robot Research, or an authorized dealer. The directories are quite nice. Although they list well over 500 active slow scanners, this number has practically doubled since printing started on the book. Some growth, huh?

Photo from KH6HJF received by K3SLJ.

The flying spot scanner article by Taggart in July *73* is destined to be a classic. Already there are many of these units in service. The generator is also used in other gear; the Plumbicon camera, 11LCF flying spot scanner, and another article to be published. If you are looking for a really great snyc generator check this one out. It's a winner.

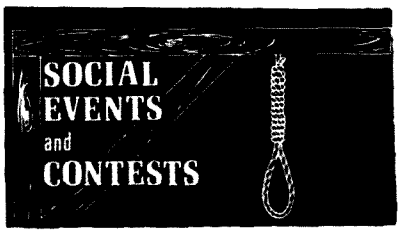


The boys' "down under" are quite busy on Slow Scan these days. Among the most active are: VK's 2BRA, 2GR, 3ARM, 3LM, 3ARD, 3AMC, 3TE, 4NP, 4XV, 5BX, 5MF, 6ES, 6CS, 7JV, 7TB, 8KK, and 8CW. ZL population consists of ZL1DW, 1AOY, 4MB and 4CU. A good many of these are not listed in the directory, so you might want to write in their calls. You can feel sure if you drag them out of a pile-up, they will be glad to swap pix. Most VK/ZL activity is on 14.230 and 28.680 MHz. Weekly net meets on Sundays, 0100 GMT. I understand a company in Melbourne has invented a new phosphor, designated P26, which can even be viewed in bright sunlight. They re-phosphor and re-gun CR tubes for a reasonable sum. I am still checking into this and will give you more information later.

If you would like to really dress up that home brew monitor, take a look at the bezels made by Millen. Designated 80073, for 3 inch tubes and 80075 for 5 inch tubes these two piece units really give a professional appearance to any monitor.

Al WØDRT (St. Louis) as seen by K3SLJ.

The most popular method of operating slow scan is to run audio and video consecutively, thus gaining the advantage of watching the pictures closely, then talking about them. But this is not the only method. Some of the fellows have run audio and video simultaneously – audio on one sideband and video on the other. Another less elaborate method is to run the audio 10 to 15 dB below the pictures (it sounds like a weak station in the background). There are any number of simple ways to mix two audio sources, from 3 resistors (like I use) to a ten dollar mike mixer, so I will not go in to circuit details here. All you need is to have another slow scanner watch your pictures, while you lower your mike level. As soon as your audio drops out of "picture interference" you have all adjusted fine. Then the front end of the monitor will get the video, and you can still be heard talking "down under" the slow scan signal.



W6EYY identification as received by K3SLJ.

Jane, ten day old daughter of Bill Arrasmith W6TEZ as seen in PA by K3SLJ.

Slow Scan on FM? Fine, closed circuit! Through repeaters? Sure, I checked into this months ago. A SSTV signal is no more than an audio signal. Deviation is the same as voice. If the repeater is within deviation limits, so is the slow scan. If an excessive audio level of slow scan is introduced into a repeater, it merely goes into clipping. And two is fine for Slow Scan experimenting.

. . .K4TWJ

The Hilton Inn at Tarrytown, New York, will be the site of the 1972 ARRL Hudson Division Convention on October 21 and 22. There will be exhibits, lectures and a banquet. Technical experts will be on hand to explain the latest gear. Registration is $3.00 and is required for forum attendance and special events. Banquet tickets are $10.00 in advance, or $12.00 at the door. There are free gifts to early registrants. To register or for more information contact Dave Popkin, WA2CCF, 303 Tenafly Road, Eaglewood NJ 07631.

The Pony Express award is available to all amateurs who make contact with five St. Joseph, Missouri operators. General and above can look for contact individually or on the CHC-FHC Service Net on 3943 kHz about 0200 GMT. At present there are only six Novice operators who are active. Novices wanting this award can look for WNØHNO WNØDPS, WNØDNE, WNØDNC, WHØHEF and WNØGGD on the following frequencies: 3710, 27120, 37130, 7158, 7166, 7168, 7170, 7176, 7180, 7186, 21110, 21120, 21132, 21150, 21170, 21177, 21180, 21200, 21220 and 21240.

The MOUNT AIRY VHF RADIO CLUB, Inc. presents the first annual Pack Rat Hamarama, Sunday October 1, 1972, at the Warwick Fire Co., Jamison Pa. The Warwick Fire Co. is located on Rt. 263 above Willow Grove and is easily accessible from Rts. 309, 202, 611, 132 and the Pa. Turnpike. Activities include a giant flea market, auction and an amateur TV demonstration by the leading local ATV'ers. Festivities begin at 10 AM. Food concession on premises. Registration is $1.00, flea market tables or tailgate sales, $2.00. Talk in on 146.94 and 52.525. For further information contact W3ZD at 520 Centennial Rd., Warminster, Pa. 18974.

The 10th Annual Greater Bay Area HAMFEST will be held at the Royal Coach Inn, just off the Bay Shore Freeway, on October 14th and 15th. For further information contact Veikke West, K6ORP, Box 751, San Mateo CA 94401.

The Quarter Century Wireless Association, Inc. will hold its 25th annual dinner meeting at 7:00 PM, Saturday, October 14, at the Twin Bridges Mariott, located on Route 1 I-95 in Washington, D.C. Senator Barry Goldwater will present the Fifty Year Awards. The guest speaker will be the Hon. Dean Burch, Chairman of the FCC. For further information contact A.J. Gironda, W2JE, Box 394, Mamaroneck NY 10543.

The Moosehorn Amateur Radio Club of the Kenai Peninsula is offering the All Alaska Counties Award. The rules are as follows: Applicant must work one station in each of the four judicial districts plus one member of the Moosehorn Amateur Radio Club. Each two-way contact must be confirmed by QSL card. QSL cards plus return postage are to be sent to Moosehorn Amateur Radio Club, Box 733, Soldotna, Alaska 99669. All contacts must be dated May, 1972, or later.

50 MHz BAND

Bill Turner WAØABI
5 Chestnut Court
St. Peters MO 63376

Andy, VE1ASJ, was much more successful on his second attempt at a DXpedition to Prince Edward Island. The rig held together this time allowing 119 contacts to be made. Best DX heard was WA6JRA, unfortunately no contact was made. Utah and Wyoming were the best DX worked. Jim, W7VDZ, made the grade while VE1ASJ was using 30 feet of wire attached to a dead tree, the regular antenna was a 6 element. Andy has a KW linear in the works which should be on the air shortly. Andy would like to make some contacts on CW in the 50 wpm bracket. Any takers may write him at P.O. Box 51, St. John, New Brunswick.

WA1EXN, Art, says, "I worked W7VDZ for state number 44 . . . also called by K7ICW (I gave him number 50 last year); nice to talk to Al again . . . have heard all the states I need this year but Montana and Hawaii."

Randy, WB4LHF, is on every Sunday evening (0100Z) looking for groundwave, scatter or whatever happens to show up on 50.110. At the same time and day you might look for the North Carolina sideband net on 50.120. Any other six meter nets around?

Earlier this summer I was in QSO with a station in the Northeast who repeatedly wondered aloud if he were being copied. Repeated assurances that his signal was running 20 over 9 didn't ease his mind, his plate current and SWR bridge told him his output was down rather drastically. A few days ago a local ham had occasion to measure the output of his exciter and linear with a borrowed Drake WV-4 wattmeter. To his surprise, the exciter (rated at 180 watts input) measured only 10 watts and the linear (with tubes totaling 750 watts plate dissipation) was putting out only 200 watts. His signal reports from both local and skip contacts had given no indication of this condition. Both the above situations point out the futility of cranking up the MIC gain or repeatedly retuning in order to get a few extra watts output. If you were, for example, running 100 watts output and being received at some distant point at "S9," then your output decreased to 6¼ watts, the net loss in signal strength would be only 2 "S" units. By the same token, if you were being received at "S2" with 100 watts output, an increase to 125 watts would not be discernible and an increase to 400 watts would be necessary to bring your signal up to "S3." From the above it should be clear that any attempt to wring the last watt out of your equipment can result only in splatter, QRM, and hard feelings – not more or better contacts. Higher power is fine, it helps when working groundwave and scatter, it even has a place during skip, just make sure your equipment is designed for the power level in use . . . or a little more.

SCIENCE HALL OFFERS CLASSES IN HAM RADIO

The Hall of Science of the City of New York will conduct a series of twelve instructional and practice sessions for teens and adults in Amateur Radio beginning September 30 at the Hall, 111th Street and 48th Ave., Flushing Meadows Corona Park.

Course for the Novice, Technician, General and Advanced class FCC Amateur Radio licenses will be presented, with all courses scheduled from 10 AM to 12 noon and repeated from 1 PM to 3 PM on consecutive Saturdays.

There is a registration fee of $5.00 and a nominal charge for text books and code practice equipment for participants who require these materials. For further information and to obtain registration form, write or phone *Hall of Science, P.O. Box 1032, Flushing NY 11352 (212-699-9400.*

LETTERS

After working at a TV station for the summer, I have a suggestion for "ham publicity." I have found that even in Rochester (I would assume it is in the top 100 market), there are a number of PSA's (public service announcement), especially in syndicated shows (Star Trek, etc.), which local stations buy and show themselves. These PSA's are picked at random from a supply of PSA's. I presume the showing of PSA's is free as they have nothing better to put there. The PSA's cover a wide range (public libraries, CAP, Army, U.S. Depts., Catholic services, etc.) and I think that amateur radio would fit in well. The best subject would probably be emergency preparedness, but other subjects could easily be used. Near the end we could put an address to contact for further information (such as ARRL) or the phone of a local radio or TV station (there are usually a few amateurs on the staff).

The best lengths for such films would be 60 sec. and 30 sec., however an "oddball" length like 40 sec. might work too.

The project seems a natural for the ARRL, however I mention it to you for your comments and suggestions.

Daniel Kinsella WA2JHF
Rochester NY

Yes, I always have and always will.
Yes, I always have and always will.
Yes, I always have and always will.
(love you)

P.S. I resubscribed

A Resubscriber

As in the "Sorcerer's Apprentice," How Do I Shut It Off? . . . the letters I mean. As a result of my offer to supply transistors to the needy or remotely located – 2 Buck •Gen – August issue, I've sent out almost 250 pieces and have run out. Never believed that many people would be interested. Received another 11 letters today and am substituting the PNP counterpart which only requires battery reversal but I'm afraid my writing arm and envelope licking tongue will not last the 30 days promised – not to mention the transistor supply.

There is sure going to be a lot of QRP 2m FM flying through the air.

I worked 4 blocks into TV channel 13 sound 215.7 MHz with the circuit using a 1X1X1 loop and 1.5–15 pF, so I guess you could say there is 220 MHz activity in Kentucky – almost Al-Al.

Walt Pinner WB4MYL

As a new Novice who also was frustrated over being able to copy only CW on my HW-16, I am now a bit happier. I performed the simple modification as shown in your August 1972 edition for HW-16's to decrease the selectivity, thus making it possible to copy AM/SSB/and foreign BC on 40m. I enjoy it as a change of listening, and it makes copying after a CQ a bit easier.

The only problem is it does result in a little extra "pop" when the key is released, due to picking up the collapsing CW signal. Solid state TR switching is the drawback there.

Keep up the MARS articles. I am a sergeant in the U.S.A.F.

Bill Armstrong WN8NKT/4
Sumter SC

The article on page 119 of the August issue entitled "FM Adapter" was of considerable interest since I am slope detecting FM signals in a communications receiver with a crystal controlled converter ahead of it. However, after reading the article and studying the schematic, I concluded that I wouldn't build the adapter on a bet. Following are the errors I have found so far in this article:

1. Page 119, first line of text – "F" left off of "Frequency."
2. Page 120, schematic:
   2.1 "J1 455 kHz INPUT" designation is confusing placed in front of the input connector ground side contact.
   2.2 Transformer T3, capacitor C10, and the "TUNE" position of switch S2 are not labeled.
   2.3 The V6b designation is adjacent to the lower section.
   2.4 The regulated 150 volt bus is tied to the 2.5 volt AGC delay voltage bus instead of the bottom of R25.
   2.5 The grid pin (1) and the plate pin (2) of V6b should be tied together as this section works as a diode.
3. Page 121, parts list – R24 is a 100,000 ohm resistor, not 1000,000 ohms.
4. Page 122, The sentence "It should be noted that the bandwidth at the receiver output jack is governed by shorting plug can be applied to the output jack when the FM adapter is not in use." is an extra collection of garbled words.
5. Page 123, – Reference 7. Handbook Preferred Circuits, NAVWEPS 16-1-519, (etc.) is NAVAER 16-1-519.

I am going to file the article until all the errata is in, and then will undoubtedly build the adapter. Am sort of disappointed in your proofreading.

Harold S. Eisley WA3SPD/W3NET
Saint Marys City MD

Picky,picky!

Received your proof (New Products, September) and have one correction. Frequency stability of the GLB Model 400B Channelizer is .0005%.

We will have a 5 kHz adapter modification for the Channelizer late this fall.

Bernie Sanders, Sales Manager
GLB Electronics
So. Cheektowaga NY

Enclosed please find my check for a subscription to *73*. After 14 years of interest in amateur radio I finally got my ticket. I was out of touch with the hobby from 1965 to 1972 and was amazed to find all of the changes that have taken place during that time. What I can't believe is the "leadership" provided by the ARRL during this period, despite their motto. To catch up on all the recent developments, I borrowed the back issues of *73* from the library of Dean Metzgar, WB4KAN/3, who also filled in the gaps with a pretty thorough history of what has been happening.

I think what the ARRL needs is a communications system which would *require* each of the section communications managers to report to headquarters two months before every directors' meeting, and also report whenever any major issue should be handled by the league. The SCM's should get opinions on all issues from the amateurs in his area. HQ would then be *required* to compile the 74 reports it receives and the information contained therein would be *required* to be presented at the board meeting.

The real problem in the ARRL is the fact that HQ decides what is good for amateur radio without consulting the amateurs. It all boils down to a "failure to communicate." Maybe they could use some of the league's money to institute a survey system whereby league members would be sent a questionnaire at least every 4 months. Something must be done.

Keep up the good work you've been doing by offering constructive criticism in your editorials, however direct and pointed it might be. You have created the finest amateur radio magazine around. Congratulations, OM.

I just heard from a local ARRL man that the ARRL is going to claim full credit for the development of 2m FM! What a farce!

Herb Brasington WA3TDI

Although it's rather far downstream by now, the article on revising the Morse Code in your November 71

issue has a lot going for it. The author has done a lot of thinking, and certainly from a time-and-motion standpoint is right on.

The chances of getting this done are, alas, very slim. It's the old story – it's easier to walk in the same old rut than to climb out and blaze a new trail. How long have proponents tried to get the U.S. to adopt the Metric System?

Many hams use a typewriter – I wonder how many ever heard about the existence of a superior keyboard, the Dvorak Simplified Keyboard? Its proponents have been trying to get this keyboard adopted by industry and government since 1944, with only sporadic success in getting anyone to listen to them. (I've used this keyboard since 1965, Wayne, and it's great.) It has the same logic and reason and time-and-motion efficiency as the Morse Code proposal. But . . . like all logical and reasonable proposals, this too must await the day when men begin to reason together.

On the basis of bandwidth, the International Code (which is really what the author is talking about, not "Morse") is not yet obsolete, and will be around for a long, long while. I have been a 55-wpm operator (ex-Navy) of International, and 35-wpm Morse (landline) op. Naturally, the code is nostalgic for me, but with great effort to separate the emotional from the rational, I'd be delighted to learn a revised signaling code if it would be as well designed as the new typewriter keyboard. I don't agree with the author's new system, but I applaud his reasoning.

W. Boyd
Geyersville CA 95441

Two meter FM does it again. Through the WA7KZC repeater located on Sherman Hill near Laramie, Wyoming, Chimney Park Scout Camp for the first time, enjoyed two way communication with the outside world.

WA7JYO, his XYL WA7SOH and junior op WA7SUL provided communication between the camp site and camp headquarters. WA7SQJ the junior op's grandmother, operated the town site to complete the family team and communication link.

Wilma E. Hirst, Ed.D. WA7SQJ
Gheyenne WY 82001

I've been reading the 73 License Study Guides – Congratulations on putting out such well written books. I let my license expire while I was away in college back in 1962, but I am again getting very interested in ham radio, especially SSTV.

I remember trying to learn radio from the manuals available back in the 1950's and wondering why anyone would want to write the English language in that fashion. Since that time, with exposure to IBM manuals and Air Force Tech data, I have learned that obscurity and circular definitions are the height of fashion among technical writers. So, thanks for the thought and time involved in putting out such lucid and enjoyable books.

Bert Mayo
Middletown CT

Well, the military can be a real drag, even in London, especially with rising costs and tourist traps within the United Kingdom. However, wherever an amateur goes, whether he is sent on his own volition or otherwise, life can be very interesting. Thank you amateur and thank you *73*. There are plenty of G5 call signs left I am told from the Ministry of Posts and Telecommunications at Waterloo and the price for a year's enjoyment is still the meager sum of three pounds. Even with the monetary crisis the way it is today, it works out to be $7.80. In addition, no renewal applications are necessary. After about two hours and seven phone calls through British red tape and an apparent language barrier between American English and English English, I've found that all they want is for the Anglo-American ham to send the money . . . renewal is taken from there as I understand it.

One might ask what reception is like on this island of islands. The answer I'm afraid has to be that you can work and indeed hear all the Italian stations you wish and perhaps more than you wish. Filters for this human QRM have yet to be developed. Perhaps in this case Johnson Island would have been a better assignment for a ham DXer.

Norman N. North WA1DBR/G5ATR
South Ruislip, England

The comment in the July issue of *73* on FCC harassment of hams, is I feel, grossly unfair to the vast majority of the FCC staff that I have come in contact with in about 37 years plus of amateur, mobile, marine and broadcasting experience.

Like the rest of us, there are some bad people working for the FCC, but there are also and have been many darned nice men that I have had contact with, and it has been my experience that if you are in the wrong, then they will issue the citation, but if it is a grey area, the vast majority are willing to accept the doubt, with just a caution, and suggestion to correct the questionable practice.

Also, as the laws are written by lawyers, different individuals can read different meanings into them, and as a result the individual FCC staffer may interpret them differently, although they do have a guideline for inspections, it still falls to the individual to make an on-the-spot decision if something is right or wrong. I do not envy them this.

There are generally about 20 to 30 DB citations and fines issued each week according to FCC public notices, with just a sprinkling of hams, at the most two or three, and most are for operating on wrong frequencies, or failure to properly identify themselves.

The one thing that has bothered me is the FCC phrase, "For repeated violation of . . . " Apparently once is just a violation, but twice is repeated, even as in amateur radio it takes place, let us say, within seconds, like two transmissions, while if it had continued as a single transmission it would have been only one violation . . . This is again the word against the action.

George W. Brooks W2GX
Newburgh NY

Here's one that might possibly be worth a hint or kink or oddity or something or other. Our small lab has a number of bench power supplies but we are constantly needing another 5 volt supply – and one that can stand a bit of abuse or carelessness, so we have placed several of National's 309K regulators on flat heat sinks with four small rubber feet that we find extremely useful. We punch out holes in the sinks, cut a hole in plastic tape slightly smaller than the stake-ins we use, place the tape on the sink covering the stamped hole, center the stake-in in the hole and fill with epoxy and let set. Then when we need five volts we just strap it across any of the available power supplies between nine and about 38 volts and have a 5 volt current limited power supply. We have a high current regulated supply of 12 volts that can get a bit nasty if you get a bit careless with shorts. I have a small screw driver that is being used now as a scriber to testify to that fact. They are easy to store and provide an instant 5 volt supply when needed. We also have the same units in several other voltages that we use the same way.

73 and congratulations on the continued excellence of *73*.

C.W. Pate
Bryte CA

I am an ARRL life member. This is addressed to all ARRL members, as well as to you to ask for your help in a matter that has been troubling me since last November. That month a guest editorial supporting the ARRL – actually a letter printed as an editorial – by James Russell, W8BU of Cleveland, appeared on page 77 of *QST*. Mr. Russell did a very unfortunate thing in that letter – he owed how we oughtn't only chastise ARRL for its shortcomings, but how we should also stand behind it as the best hope for a strong, viable amateur radio. This would've been fine except that Mr. Russell used the case of a young Cleveland welfare recipient to support his argument. Quoting from the Cleveland 'Press,' Mr. Russell let us know that the young girl con-

FREQUENCY SYNTHESIZER for 2 METER FM

Part II

Last month we started describing our frequency synthesizer and gave the parts list. This month we will show all the diagrams and describe how it works, and next month we will have the printed circuit board layout, parts layout drawings, and construction and operation information.

Figures 2 thru 12 show the diagrams of the various parts of the synthesizer. To see how these parts fit together refer back to Fig. 1, the block diagram, in last month's article.

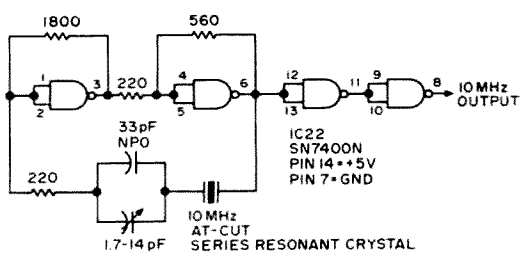

Fig. 2. 10 MHz crystal oscillator.

10 MHz Crystal Oscillator (Fig. 2)

The basic reference for the synthesizer is an AT-cut series resonant 10 MHz crystal in a simple circuit using the four gates from an SN7400N IC. This is a fairly simple circuit which is stable enough for the prupose. If you want the utmost stability, though, you may want to put the entire circuit into an oven. The crystal oscillator circuit is mounted at the very edge of the p.c. board, and so is easily removed later, if you want. But we haven't found this necessary so far.

Reference Frequency Divider (Fig. 3)

This frequency divider takes the 10 MHz signal from the crystal oscillator and divides it down into the reference frequency needed

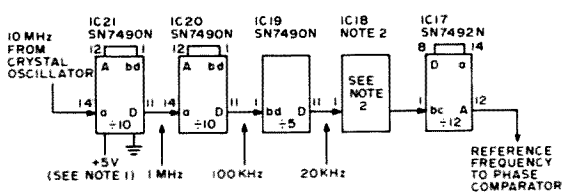

Fig. 3. Reference frequency divider. Notes: 1. All ICs shown have +5V to pin 5, and ground to pins 2, 3, 6, 7, and 10; 2. IC18 type and wiring depends on desired synthesizer output frequency as follows:

Synthesizer Output Freq.	IC18 Data Type	Divides by	Output Pin	Output Freq (Hz) from IC18	from IC17
6 MHz	SN7493N	8	11(D)	2500	208-1/3
8 MHz	SN7492N	6	8(D)	3333-1/3	277-7/9
12 MHz	SN7493N	4	8(C)	5000	416-2/3

by the phase comparator. In our version, which provides 6 MHz output, the reference frequency divider provides a reference frequency of 208-1/3 Hz. For a synthesizer output of 8 MHz, the reference would be 277-7/9 Hz, and for a 12 MHz output the reference would be 416-2/3 Hz. The division from 10 MHz down to these frequencies is done by five IC's. The note at the bottom of Fig. 3 tells the differences in hookup for the three different circuits.

Phase Comparator (Fig. 4)

The reference frequency and the output from the programmable divider both go into the phase comparator, where they are compared. If there is any difference in the two, a control voltage to the VCO changes the VCO frequency to bring it back to the right frequency.

We tried many circuits before coming up with the one in Fig. 4. There are several integrated circuits specially designed for phase-locked-loop applications, and we tried them all. Signetics makes a series of phase-locked-loop IC's which contain the phase detector, several amplifiers, and the VCO all in one, but we found the performance unsatisfactory. Likewise, Motorola makes a phase comparator IC which also did not work out well. An "exclusive-OR" circuit made out of an SN7400N gate package was also disappointing. In each case, the problem is that the output of the phase comparator has to be a pure dc voltage proportional to the phase or frequency difference between the two input signals, while each of the IC phase detectors has a large amount of feed-through of the input pulse signals. While the IC manufacturers claim that you can get rid of these pulses with heavy filtering, that does not quite result in a clean enough output. In our circuit we have managed to eliminate all traces of the input pulses on the output line.

The reference frequency input into the phase comparator is a square wave which is applied to an integrator circuit consisting of the 1K resistor and 1 μF capacitor. These two components shape the square wave into a somewhat distorted triangular wave with curved edges, which is then applied to the source of an MFE 3002 FET. This is an enhancement-type MOSFET which acts like a very fast switch.

At the same time, the output from the programmable divider is applied to the base of Q3. The signal coming in is a series of very narrow pulses (on the order of a tenth of a microsecond wide) whose repetition rate is equal to the reference frequency (when the synthesizer is operating normally). The .001 capacitor in the collector circuit of Q3 widens these pulses to about a microsecond wide, so that the output of Q4 are wider pulses. Between pulses, the output of Q4 is about zero volts, and each pulse goes up to about +12 volts.

These positive-going pulses are connected to the gate of Q1. Q1 forms what is called a "sample-and-hold" circuit. When its gate is held around zero volts (between the pulses from Q4) Q1 acts like an open switch. But during the 1 μS wide pulses, when the gate of Q1 is at +12 volts, Q1 acts like a closed switch. Hence, for a very short instant during each pulse, Q1 connects the 1 μF and the 0.1 μF capacitors together, charging the 0.1 μF capacitor to the exact voltage that happened to be on the 1 μF capacitor at the instant that the pulse occurred.

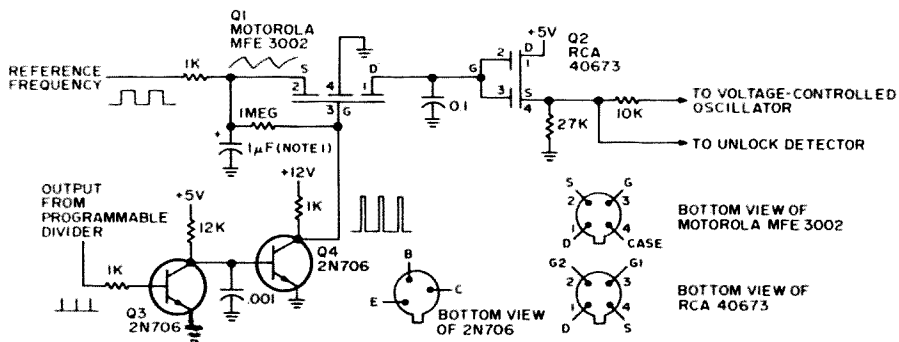

Fig. 4. Phase (and frequency) comparator. Notes: For 8 MHz, change to .75 μF, for 12 MHz change to 5 μF.

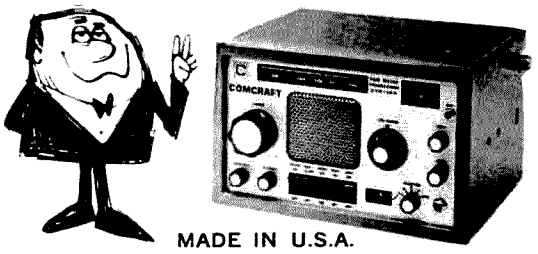
If the pulse frequency out of the programmable divider is exactly the same as the reference frequency, then the pulses always occur at the same time in relation to the triangular wave; in that case the voltage across the 0.1 μF capacitor will always be the same, since the FET switch will always sample the same part of the triangular wave. But if the two frequencies are not the same – so that the pulses occur either more often or less often – then the FET switch will sample different parts of the triangular wave, and the voltage across the 0.1 μF capacitor will change.

The output of the 0.1 μF capacitor is connected to a source-follower, using an RCA dual-gate-protected MOSFET, the 40673. The source-follower is very similar to a cathode follower, and provides a very high input resistance to the 0.1 μF capacitor. The purpose here is to monitor the voltage across the 0.1 μF capacitor without loading it down, so that the voltage across the capacitor stays constant even between successive input samplings – this is what is meant by "sample-and-hold." The output from the source-follower is then sent to the unlock detector and to the VCO.



As pointed out earlier, the output from the phase detector is a constant dc voltage when the synthesizer is operating normally. This dc voltage is in the range of about 1.9 to 4.4 volts, and is used to control the frequency of the VCO. Under normal operation, we say the loop is locked on the reference signal. But if the phase detector output is changing, that means that the two inputs into the phase detector were not the same frequency, and thus the VCO frequency is changing. Under these conditions we say that the loop is not locked, and the unlock detector senses this by seeing that the output of the detector is a changing voltage.

Voltage-Controlled-Oscillator (Fig. 5)

The VCO is another tricky part of the system and we must confess that we are not quite happy with this one yet. The heart of the VCO is a Motorola MC1648P ECL oscillator IC, which uses L1 and C1 to set its frequency. The output of the IC is amplified and conditioned by a 2N5771 transistor, and

2 Rigs in one!

THE **COMCRAFT** CTR-144

MADE IN U.S.A.

The First AM-FM Solid-State Transceiver For Two Meters

No longer is it necessary to choose between AM and FM on two meters. Now you can have both in one compact unit. Join the gang on the new FM repeaters yet still be able to "rag chew" with old friends either AM or FM anywhere in the two meter band.

COMPARE THESE FEATURES

TRANSMITTER:

- Built-in VFO (Frequency converted for stability)
- AM and FM both crystal and VFO
- Four transmit crystal positions (8 MHz)
- 12 watt input AM and FM
- High level transmitter modulation on AM
- Bandpass coupled transmitter requiring only final tune and load
- Three internal transmit crystal sockets with trimmers for netting
- One transmitter crystal socket on the front panel
- Deviation limiting
- 146.94 MHz crystal included

RECEIVER:

- Double conversion
- Crystal controlled first conversion
- MOS FET receiver front-end
- Integrated circuit limiter and discriminator for FM
- Envelope detector and series gate noise clipper for AM
- Built-in squelch for both AM and FM

GENERAL:

- Separate transmitter and receiver tuning
- Built-in 115VAC power supply
- Direct 12VDC operation for mobile or portable operation
- Optional portable rechargeable snap-on battery pack available
- "S" Meter also used for transmitter tune up
- Military style glass epoxy circuit boards
- Anodized lettering and front panel
- Baked epoxy finish on the cabinet
- 47 transistors, 22 diodes, 1 integrated circuit
- Dimensions: 10¼"W x 6¼"H x 7½"D

Warranty—90 Days Parts and Labor

The CTR-144 is available at your DEALER

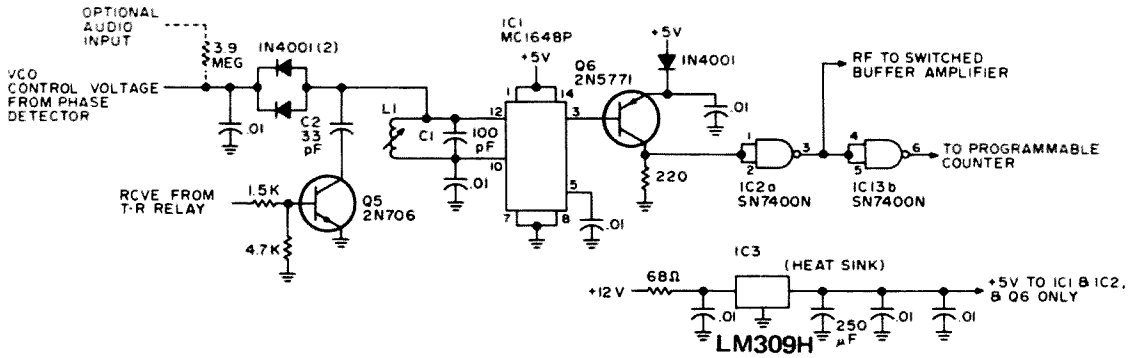

Fig. 5. Voltage-controlled oscillator. Notes: L1 is 26 turns of No. 32 enamel wire close wound on 7/32 in. dia. by 19/32 in. long ceramic core, with ferrite slug (6 MHz output). Coil is adjustable from 3 to 6 µH, and is normally set to about 4.8 µH (6 MHz output).

then further amplified and buffered by some gates before being sent to the rest of the system.

The values specified for L1, C1 and C2 in Fig. 5 are for 6 MHz operation only; we haven't built the 8 or 12 MHz versions yet, and so the choice of coil and capacitor for other operating frequencies will be up to you. We will discuss in a moment the way to decide these values.

The oscillator is tuned over its range by changing the shunt capacitance across the tuned circuit. Instead of using a varicap diode, we found two paralleled 1N4001 diodes just as good. The VCO control voltage (which is positive) is applied to the cathodes of these two diodes. The higher this positive voltage, the lower the diode capacitance, and the higher the operating frequency.

Because the oscillator has to operate at a lower frequency during receiving, we switch in another capacitor, C2, just during receive. This is done by applying +5 volts to the base of Q5, turning it on. When Q5 is off, C2 is essentially out of the circuit, except for about 5 pF circuit capacity.

Since the phase comparator output ranges from about 1.9 to 4.4 volts, we designed the VCO to cover the entire range with a control voltage from 2.2 to 4.1 volts, which leaves a 0.3 volt overlap at both ends, to make sure that enough control voltage is available from the phase detector to control the VCO over the whole range. On our 6 MHz synthesizer, the output frequency during transmit is in the range of 6041 to 6167 KHz, and during receive is in the range of 5595 to 5721 kHz. Hence our VCO is designed to satisfy the following data:

	Output Frequency from VCO (kHz)	
Input Control Voltage	Transmit (0V on base of Q5)	Receive (+5V on base of Q5)
+2.2V	6040 or less	5595 or less
+4.1V	6170 or more	5725 or more

If you build the synthesizer with 8 MHz output, then the transmit output frequency range is from 8055 to 8222 kHz, and the receive range (assuming 10.7 MHz i-f offset) is 7461 to 7628 kHz. Then you will have to change L1, C1, and C2 to get the following:

	Output Frequency from VCO (kHz)	
Input Control Voltage	Transmit (0V on base of Q5)	Receive (+5V on base of Q5)
+2.2V	8055 or less	7460 or less
+4.1V	8225 or more	7630 or more

Notice that in each case we add a little overlap, just to make sure that the final circuit is going to work properly. If you want 12 MHz output, then the output frequencies will be twice those in the 6 MHz case. Also, for 11.7 MHz receive offset, the receive frequencies will be a little lower than those shown above.

In order to keep the noise and hum out of the VCO, we found it necessary to put the VCO into a corner of the board, separated by a ground strip from all other components on the board, and had to install a separate +5V regulator. We used an LM309H regulator with a small clip-on heat sink. The LM309H is similar to the LM309K regulator, but is in a small TO-5 style can instead of the big TO-3 case. You can use the LM309K instead, if you wish, but it will not fit

directly on the board. If you mount it on the chassis, make sure to insulate it from the chassis ground. Instead, bring a separate ground wire back to the VCO and ground it where the LM309H would have been grounded. You must avoid all ground loops to avoid problems.

It is possible to FM modulate the VCO to produce a very nice signal, by simply feeding about 1V of audio to the VCO control input through a 3.9 MΩ resistor. You can reduce the value of this resistor a bit, but if it is made too small then probably you will get hum from the audio input because of a ground loop. In our case, we have a Touch-Tone pad mounted on the case, and this is where we bring in the audio. If you want to voice modulate the VCO, make sure to put in a cut-off filter into the audio path to cut off below about 500 Hz. Any audio introduced at this point that is at a lower frequency than the reference signal at the phase comparator will appear as an error in the phase-locked-loop, and the loop will try to correct for it. You won't get much modulation, and it will just make the loop a little more unstable. We're planning to try to feed in PL tones at this point in the future, but suspect that it won't work out too well.

As mentioned earlier, we are not too happy with the VCO at this point, primarily because it has a little noise. The output has a bit of random residual FM, which shows up on the transmitted signal as a hiss. Since it is not too objectionable we decided to accept it in the interests of simplicity, but may get ambitious on this circuit in the distant future.

Unlock Dectector (Fig. 6)

A relatively straightforward circuit checks whether the loop is locked by monitoring the VCO control voltage. An emitter-follower, Q7, is connected to the control line, with its output driving Q8, an amplifier, whose output in turn goes to Q9 and Q10. Both Q9 and Q10 are normally biased just below turning on. If an ac signal is present, one or the other of these two transistors turns on. In normal operation, pins 13 and 12 of IC13d are at about +5V. If Q9 turns on, pin 13 is grounded; on the other hand, if Q10 turns on, then the input into IC13c

Proved in Commercial 2-way
Now Available To Amateurs!

Larsen Mobile Gain Antenna 144-148 MHz

The result of over 25 years of two-way radio experience. Gives you . . .

- **3 db + gain over 1/4 wave whip**
- **6 db + gain for complete system communications**
- **V.S.W.R. less than 1.3 to 1**
- **Low, low silhouette for better appearance**

The fastest growing antenna in the commercial 2-way field is now available to Amateurs. It's the antenna that lets you HEAR THE DIFFERENCE. Easily and quickly adjusted to any frequency. Hi-impact epoxy base construction for rugged long life. Silver plated whip radiates better. Handles full 100 watts continuous. Models to fit any standard mount. Available as antenna only or complete with all hardware and coax.

Get the full facts on this amazing antenna that brings signals up out of the noise . . . provides better fringe area talk power. Write today for fact sheet and prices.

Sold with a full money back guarantee. You hear better or it costs nothing!

also available . . .
5 db Gain Antenna for
420-440 MHz and 440-460 MHz

Phased Collinear with same rugged construction as Larsen 2 meter antennas and 5 **db** gain over reference 1/4 wave whip. Models to fit all mounts. Comes with instructions. Write today for full fact sheet and price.

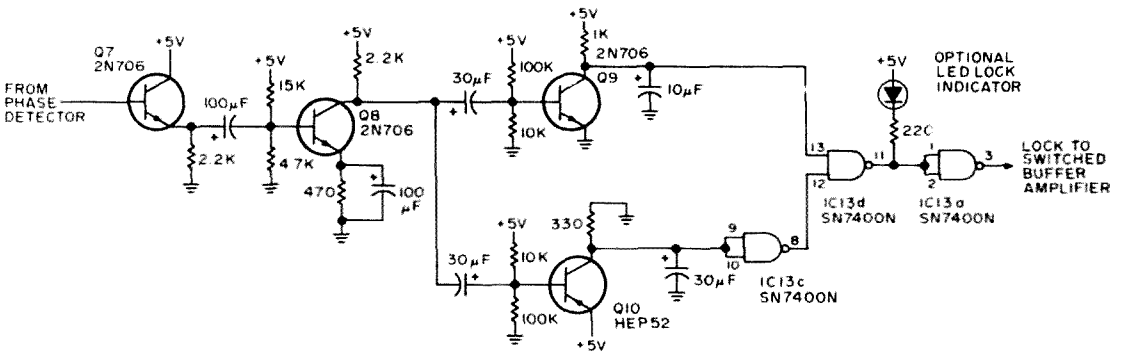

Fig. 6. Unlock detector.

goes to +5V, and the output of IC13c ground pin 12 of IC13d. Either of these two conditions brings pin 11 to +5, turning off the optional LED LOCK indicator, and bringing the LOCK signal, which goes to the switched buffer amp, to about 0V. This LOCK signal is about +5V (a binary 1) when the loop is in lock, and goes to ground (binary 0) when the loop is unlocked.

The optional LED diode makes a very handy way of checking whether the loop is locked or not. There is room for the diode right on the p.c. board, or it may be brought out to the front panel. When the diode lights we have a fairly nice way of making sure that everything is operating normally.

Switched Buffer Amplifier (Fig. 7)

The switched buffer amp uses three two-input gates in IC2 to buffer the output. When the LOCK signal from the unlock detector is a logical 1 (+5V) the gates are on and the rf signal is sent to the multipliers. If the LOCK signal goes to zero, the gates are turned off and the output is disconnected.

Programmable Divider (Fig. 8)

Although this circuit looks the most complicated, it is actually very easy to understand. IC4 through IC7 are programmable decade up-down counters which, along with IC12, do the actual counting. As mentioned earlier, the value of N, the

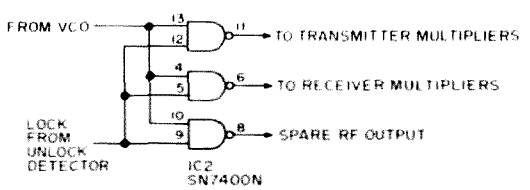

Fig. 7. Switched buffer amplifier.

number by which we divide, is a constant between 29,000 and 29,599 during transmitting, and is 2140 less during receiving. Temporarily forget about what happens during receiving, and look at the numbers 29,000 and 29,599. Since the digits 29 at the beginning are the same all the time, IC12 is permanently wired to count to 2, while IC7 is permanently wired to count to 9. The last three digits of N are entered into IC6, IC5, and IC4, in that order, by the 11 pairs of diodes connected to pins 15, 1, 10 and 9 of those IC's (pin 9 of IC6 is always grounded since that bit is always a 0). The actual connections to those diodes are shown later.

To see how the divider works, let's take an example. Suppose we want to transmit on a frequency of 146.940 which corresponds to a value of 29,388 for N. The digits 29 are permanently wired into IC7 and IC12, the 3 is set into IC6, and the digit 8 is set into both IC4 and IC5. In this way the counter is preset to the starting value of 29,388. As soon as this is done, each input pulse from the VCO circuitry subtracts one from the counter. After exactly 29,388 input pulses the counter gets down to a count of 00000, and we repeat the whole process all over again.

In actuality, there is a bit of fancy footwork required to do all this; to understand all of the fine detail, we have labelled some of the lines in Fig. 8 with letters A through F. After the counter starts counting down toward zero, a number of things happen. First, IC12 gets down to a count of 0; when this happens line C goes high (meaning positive, or about +5V). A short time later, when IC7, IC6, and IC5 all reach

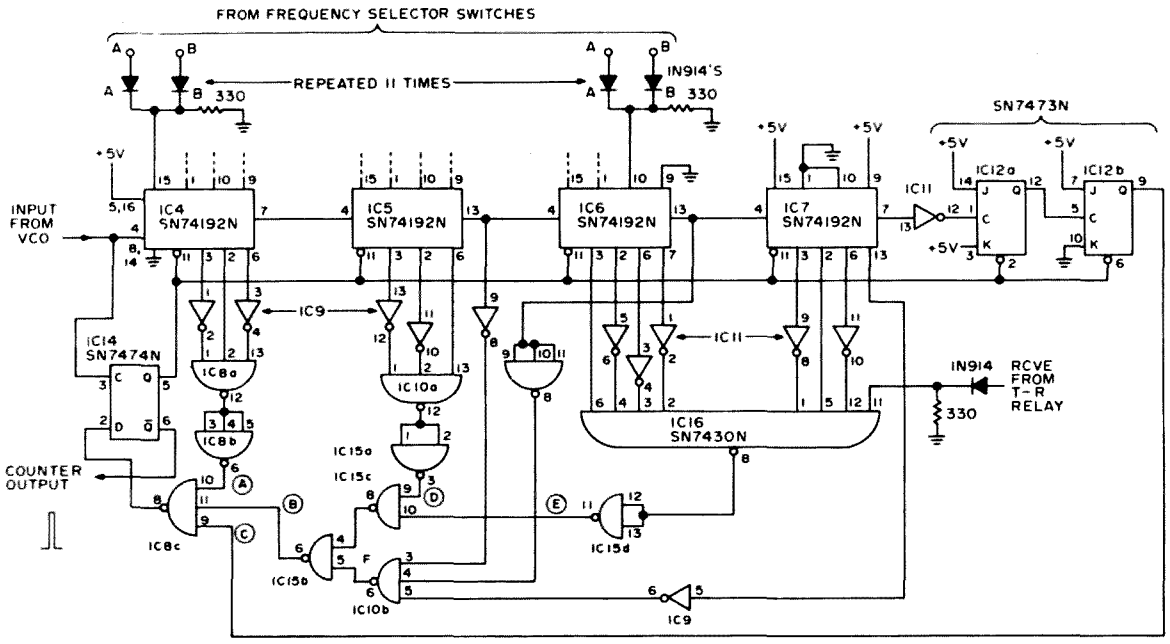

Fig. 8. Programmable divider (÷N).

the count of 0, line F goes low (near zero volts); therefore line B goes high. Then IC4 reaches a count of 2, line A goes high. Thus when the counter has gone from its original preset count down to a count of 00002, the output of IC8c goes low. This applies about zero volts to the D input of IC14, a so-called Type-D flip-flop, but the flip-flop does not react until the next input pulse. At this pulse the counter tries to count down to 00001. But at the same time IC14, which was set until now, resets and its Q output grounds the load lines, pins 11 of IC4 through IC7, and pins 2 and 6 of IC12. This forces all of the counter stages to preset back to the starting value of 29,388. But the counter can't start counting yet – it has to wait until the next input pulse (when the counter would otherwise have been at the count of 00000,) at which time IC14 sets again.

Hence IC14 goes through a complete set-reset-set cycle exactly once every 29,388 input cycles (or whatever N corresponds to the frequency selected), which gives us the frequency division by N. The output from pin 6 of IC14 is a short positive pulse occurring exactly once every N input pulses.

When the synthesizer is switched into receive mode, the T-R relay puts +5V on the RCVE line, which in turn makes pin 11 of IC16 go high. This brings IC11, IC15, and IC16 into the picture. As before, the counter starts to count down from its preset value towards zero, but this time it never reaches anywhere near it. As soon as IC7 and IC6 reach a count of 21, line E goes high. When IC5 reaches a count of 4 line D goes high, and so line B goes high. Lines A and C work the same as before, and so the entire reset process starts when the counter gets to a count of 02142, and resetting finishes at the count of 02140 (instead of 00000 as in transmit). Since this reduces the quantity N by exactly 2140, it drops the frequency (after it is multiplied up to the two meter range) by exactly 10.7 MHz.

If the first i-f frequency of your rig is different from 10.7 MHz, then it will be necessary to change this circuitry. For an 11.7 MHz i-f (such as in the Standard transceivers), for example, we need to start resetting the divider at a count of 02342 instead of 02142. In this case the change is very simple – just eliminate the inverter shown as IC11 pins 5 and 6. Probably the best way to do this on the board is to cut off pins 5 and 6 on IC11's socket to disconnect the inverter, and then put a jumper between pins 5 and 6 on the board.

Notice also that we subtract the count of 2140 from the quantity N, we don't add it. That means we can only accomodate oscillator injection on the low side of the received signal. This fits most imported

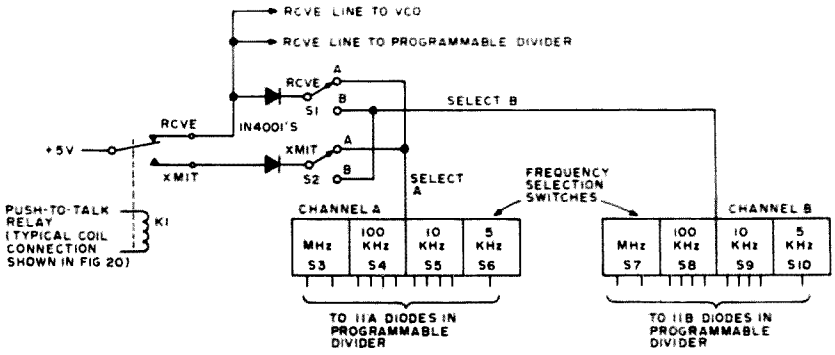

Fig. 9. T-R Relay and channel selection switches. Note: See Fig. 10 for detailed wiring of S3 to S10.

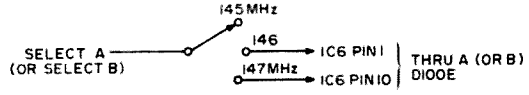
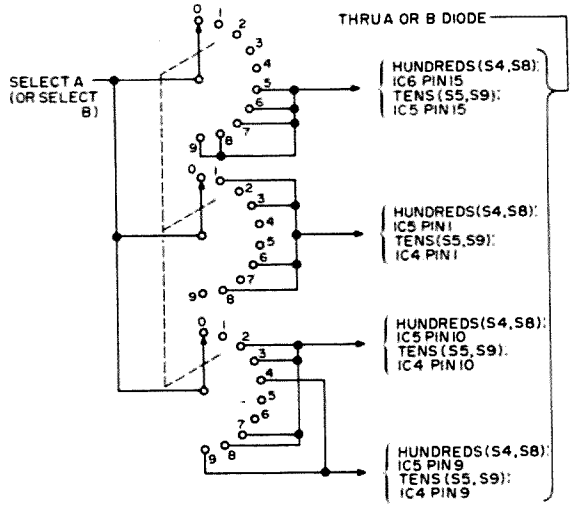
transceivers. But if you own the Yaesu transceiver, which uses high side injection, the changes required to the synthesizer are really major, and it probably doesn't pay to use the available printed circuit board.

T-R Relay and Channel Selection Switches



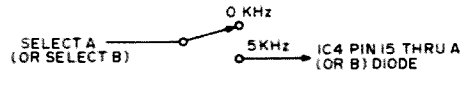
Undoubtedly we could have replaced the push-to-talk relay shown in Fig. 9 with a transistor, but the relay is more universally adaptable to most transceivers, and so we used it. When the relay is deenergized the synthesizer is in the receive mode, and +5V is supplied to the RCVE channel switch S1, to the VCO (to turn on the transistor which switches extra capacitance into the VCO tuned circuit) and to the programmable counter (to cause subtraction of 2140 from the factor N). When the synthesizer goes to transmit, +5V is only supplied to the XMIT channel switch, S2.

The RCVE and XMIT channel switches select either channel A or channel B for operation, and in turn send +5V to either the channel A frequency selector switches (S3 through S6) or the channel B frequency switches (S7 to S10). In this way we get independent frequency selection for transmit and receive, which you need for going through a repeater. For simplex operation you can also preset two different frequencies and simply flip back and forth. With only a little more effort, you could add a scanning circuit which would automatically go back and forth between frequency A and B; it would have to work slowly, though, since the synthesizer takes about 1/4 to 1/2 second to settle on a new frequency (it will take less time if the two receive frequencies are close together).



Frequency Selection Switches (Fig. 10)

As shown back in Fig. 8, there is a total of 11 preset inputs brought out from IC4, 5, and 6. Each input goes to ground through a 330Ω resistor, and also goes to two diodes. Of each pair of diodes, one goes to the channel A frequency selection switches, and the other goes to the channel B switches. The diodes are there to isolate the two sets of switches from each other.



The actual wiring of these switches is shown in Fig. 10. The MHz switches (S3 and

a. MHz selection switches S3 and S7.

b. Hundreds (S4 and S8) and Tens (S5 and S9) switches.

c. 5 kHz selection switches S6 and S10.

Fig. 10. Wiring of frequency selection switches S3 through S10.

S7) are single-pole, three-position rotary switches; the hundreds of kHz switches (S4 and S8) and the tens of kHz switches (S5 and S9) are all three-pole ten-position rotary switches, and the 5 kHz switches (S6 and S10) are single-pole two-position rotary switches. The wiring to these switches is not BCD coding, by the way, and the thumbwheel BCD switches you see occasionally sold surplus can't be used here.

Power Supply (Fig. 11)

The synthesizer is designed to work from +12V, and the power supply consists mostly of regulators and filtering. A simple series regulator using a 2N3055 or similar NPN silicon power transistor is used as a preregulator to keep large changes in input voltage (as in mobile operation) from affecting the unit. The resulting voltage, which is a bit under +12V, is then sent to the VCO (which has its own regulator), the phase detector (where additional regulation is not needed), and to an LM309K IC regulator which provides the +5V at about 0.6 ampere, needed by most of the logic circuitry.

The LM309K in the main regulator should be mounted on a heat sink or on the chassis. The LM309H in the VCO circuitry mounts right on the board, and should have a small clip-on heat sink. The 2N3055 and the 12V zener should also be heat sinked or chassis mounted.

Frequency Multipliers (Fig. 12)

The frequency multipliers take the output of the synthesizer and multiply it up in frequency to whatever value is needed by your transceiver. Since various transceivers need different amounts of multiplication, we

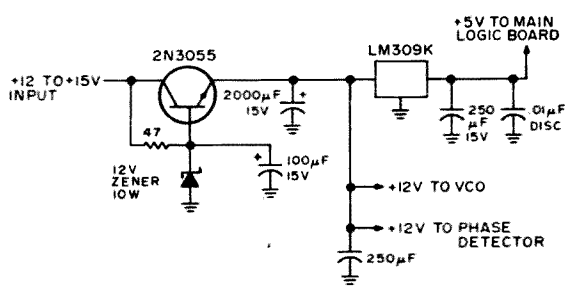


Fig. 11. Power supply.

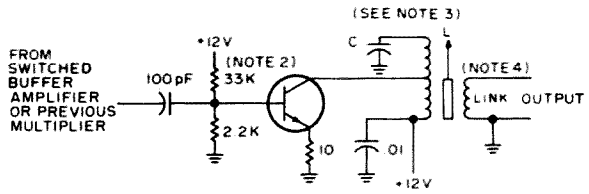

Fig. 12. Frequency multipliers. Notes: 1. Uses components and board of International Crystal PAX-1 rf power amplifier; 2. Add a 33K resistor into holes marked R on PAX-1 board; 3. Select L and C as shown in PAX-1 instructions for range covered. Adjust for max output with synthesizer set for 146.5 MHz; 4. Use 10-turn link with yellow coil and 5-turn link with red coil for coupling to next multiplier. Experiment with correct number of turns on final link to transceiver.

decided not to design our own, but to simply use a commercially available amplifier, the PAX-1 power amplifier from International Crystal.

As shown in Fig. 12, the circuit is quite simple. As it comes in the kit, the amplifier is designed for class C and needs quite a bit of drive. We added a 33K resistor to provide some base bias (it mounts in a set of holes already provided on the board) and found that it works very well as a frequency multiplier. Though it is only rated as being good up to 30 MHz, we found that it works at 45 MHz. In our unit we use four of these units, one to triple from 6 MHz to 18 MHz for our transmitter, and three to double from 5.6 MHz (during receiving) to 11.2 MHz, then to 22.4 MHz, and finally to about 45 MHz. The kit comes with three color-coded coils which cover the range through 45 MHz. But disregard the instructions provided with the kit as to the number of turns in the link, and use the number of turns specified in Fig. 12 between multipliers. The last link, used to couple from the multiplier to your transceiver, will have to be chosen experimentally. If you have an rf voltmeter or high frequency oscilloscope you are in luck, since then you can measure the voltage drive using a crystal, and tailor the link to provide the same voltage.

In the third part of the article, we will show you how the printed circuit board is laid out, where to place the parts, and how to hook the whole thing up.

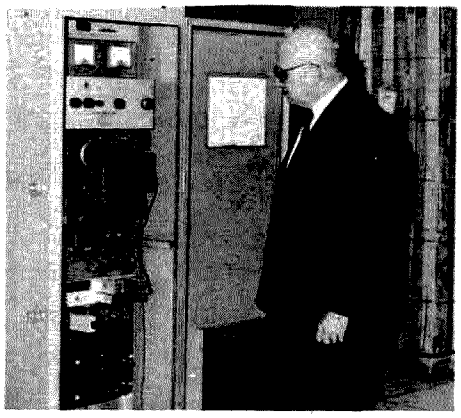
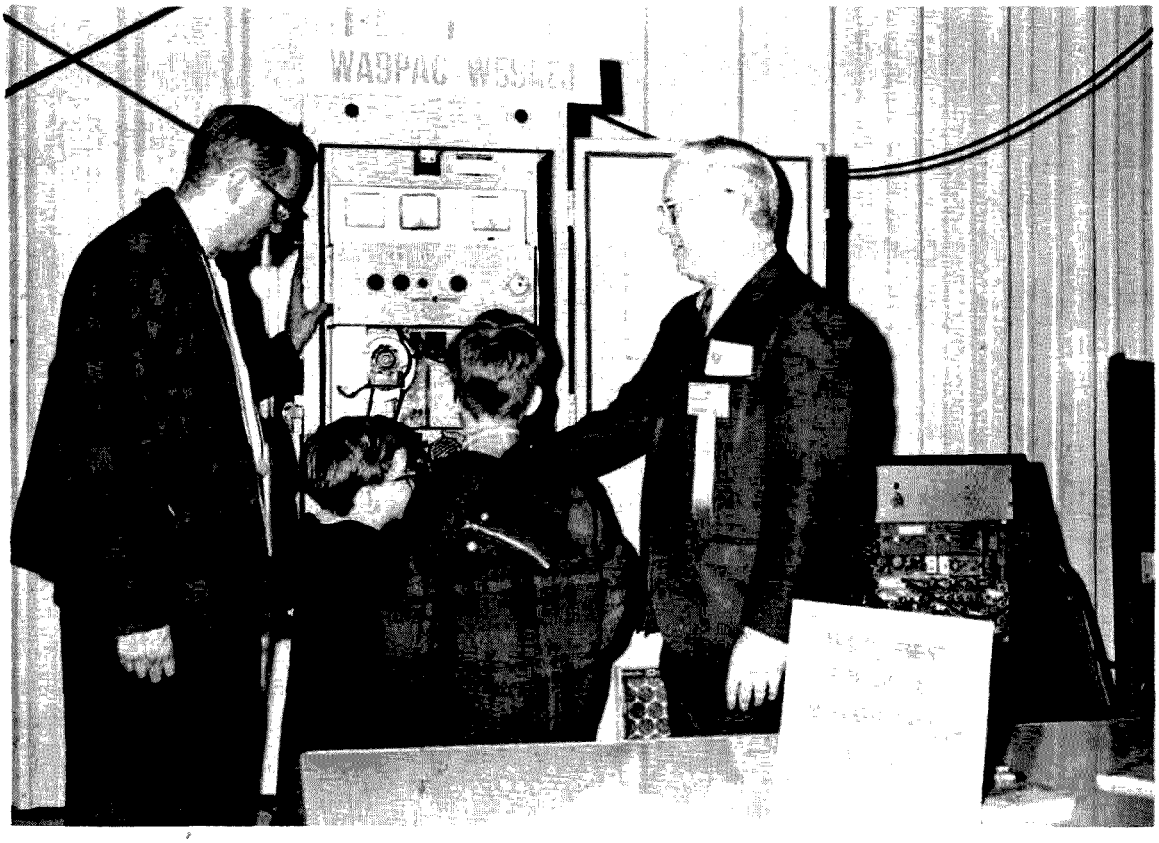
A BIG NEW VOICE IN CHICAGO

A powerful new repeater is on the air in Chicago. It has been established by the Pioneer Amateur Radio Club, a group that has become known more by its QSL cards than by its publicity. Most of the club members are professionals in the communication field, and their club's story is an interesting one.



The telephone industry has a sort of old timer's club that has been named "The Telephone Pioneers of America." Membership is open to anyone who has worked in the telephone industry for 21 years or more. Local chapters are numerous and most metropolitan areas are likely to have several. While much of their time is devoted to public service work, they also encourage their members to develop hobbies that will hold their interests in their retirement years. As you might expect, the telephone business has a healthy share of radio hams, and so an amateur radio club made up of active and potential telephone pioneers is a "natural."

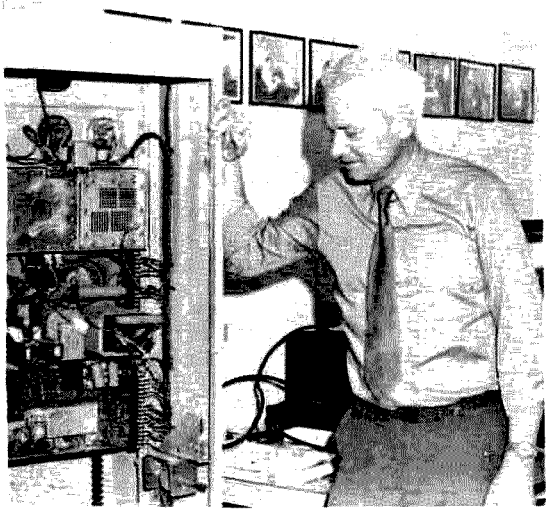
In Chicago, the Pioneer organization has made office space available to the radio club and the hams have made good use of WA9PAC has been on the air for sever. l years with CW, sideband, 2m and 3/4m FM equipment. In January of this year, they started regular operation of a repeater under the call WB9AEJ. Talk-out is presently on 449.60 MHz while the talk-in frequency is 449.85 MHz. A change of the talk-out frequency will soon be made to 447.85 MHz. The transmitting antenna is over 500 feet above street level just west of Chicago's loop; and ERP of about 600 watts has been achieved.



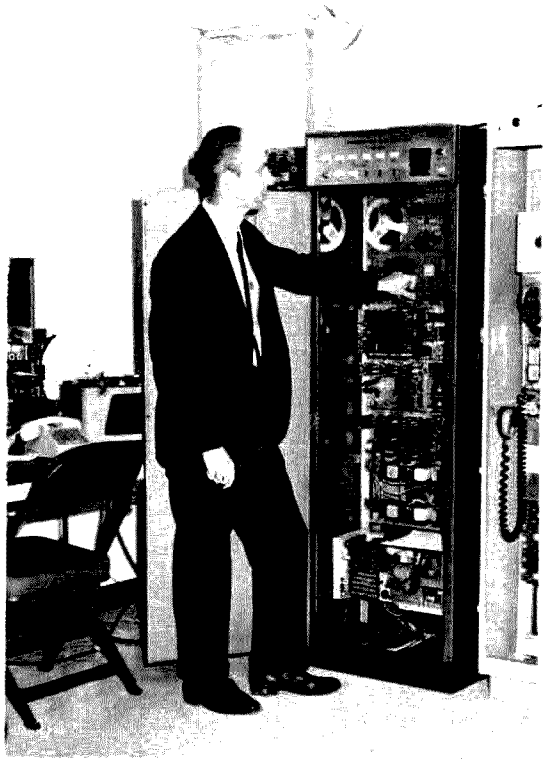
The repeater is open to all users a d is carrier-controlled. Receiver selection ci.cuits prevent more than one receiver from getting

Len Bateman, K9ZNE, makes an adjustment on the automatic voice identifier. The entire cabinet is used as the repeater control terminal; it ties together the base transmitter, remote receivers, wire-line control circuits and the remote control points. The cabinet on the right contains a test transmitter that is used to key up the remote receivers for test purposes. The repeater is normally open to all users and is carrier operated.

Dan Bohi, W9HZJ, takes a quick look at the base transmitter. This rig is located under the roof of a building just off of the west side of Chicago's loop. It transmits on 449.60 MHz with an ERP of about 600 watts. The control terminal and the fixed receivers are in other buildings. This transmitter is part of the repeater that operates under the call sign WB9AEJ. Talk-in is on 449.85. The antenna is more than 500 feet above street level.



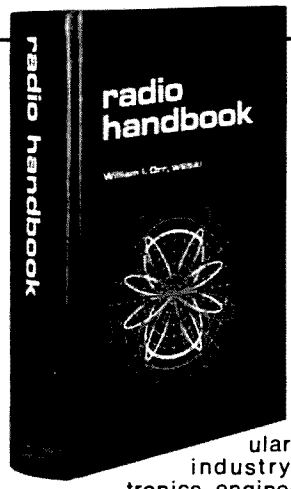
On Sunday, April 9, 1972, portable rigs were on the air from a hobby show in Northbrook, Illinois. George, W9NLT (right) is shown explaining all about ham radio (in 25 words or less) to two young visitors.



to the transmitter at one time. Another interesting feature is the soft feminine voice that identifies the transmitter. The transmitter is controlled by wire line from three authorized control locations. While only two receivers are currently in operation, the club is hoping to establish two more in suburban locations by late spring.

Ray Fusick, K9FBL, checks out a teleprinter with loving care. On RTTY at home, Ray will be active in work on and with an FSK rig that is being planned for the station.

Bob Klein W9KRZ, may be smiling at the idea that he is looking at a "portable" rig. This cabinet is to be taken to hobby shows and similar displays of spare time activity. It will communicate with other stations through the repeater, WB9AEJ.



Don Dehn, WB9CXE, has just completed a frequency check on the test transmitter and is shown adjusting the record level on the logging tape recorder.

One activity that appeals to club members is setting up a portable station at hobby shows, hamfests or other appropriate affairs. They have constructed two portable rigs that can be taken out to shows and set up on reasonable notice. Communication will be with other stations via the repeater. Several of the hams in the pictures also work the hobby shows from their home QTH. On March 19, visitors to shows at Glenwood and Oak Brook, Illinois were able to talk through the repeater. Several hundred people were present at each location and the ham exhibit was considered to be one of the main attractions.

Club President Don Dehn, WB9CXE recently announced the results of the seventh annual Pioneer QSO party. With a record high of 446 stations participating, WA9PAC took second place in the club station award category. It was operated by George Hickman, WA9QIA and his son George Jr., WA9QHZ. The Chicago group placed third in the chapter award category.

Pre-publication price only
$13.95

By far the most popular manual in the radio industry for amateurs, electronics engineers, and technicians, this comprehensive book has been completely revised and updated by its author, William I. Orr, W6SAI.

LATEST HOW-TO-BUILD DATA
The new 19th Edition of Radio Handbook contains authoritative, detailed instructions for designing, building, and operating all types of radiocommunications equipment. It provides a complete understanding of the theory and construction of all modern circuitry, semiconductors, antennas, power supplies, full data on workshop practice, test equipment, radio math, and calculations.

AN INVALUABLE REFERENCE
Gives the broadest coverage in the field, including the latest information on new high-frequency linear amplifiers of 1 and 2kw PEP output featuring the new 8874 and 8877 tubes, a new solid-state LED-readout receiver, new high-performance 2-meter "moonbounce" converter, and solid-state f-m amplifiers for vhf. All equipment described is of modern design, free of TVI problems. 6½" x 9¼"; hardbound.

PREPUBLICATION OFFER!
No. 24030, New 19th Ed. Radio Handbook
Special price until Nov. 30, 1972 $13.95
(After Dec. 1, 1972, regular price will be $14.95)

SOLID STATE 6 METER CRYSTAL-HET-VFO

This describes the basic design, circuit, and theory of a solid state crystal-controlled, battery-operated, heterodyne vfo using low-cost transistors, which delivers a stable 120 mW output from 50 to 51 MHz.

The new Miller two-speed dial is used on the vfo which makes zero-beating a pleasure. A stable oscillator operating from 5 to 6 MHz beats with a 45 MHz crystal oscillator to produce 50 to 51 MHz energy in the mixer output. An rf amplifier brings up this output to 120 mW.

The main feature of this exciter is the *addition* of the stable 5 to 6 MHz vfo to the crystal oscillator, thus avoiding the usual *multiplication* of any shift or drift.

Emphasis is on the basic theory and circuit design. Features that can be added later include a low-pass filter for the low-frequency vfo, crystal switching for greater coverage, direct crystal control, and packaging.

Block Diagram and Overall Schematic

Figure 1 shows the block diagram with the rf output from the 5 to 6 MHz vfo and the crystal oscillator going to the mixer. This type of circuit has been used with success by the military services for many years. It is hard to imagine a better combination of low-cost transistors giving an equally stable variable frequency, easy-to-build, vfo. A tuned amplifier following the mixer serves to further reject unwanted frequencies and amplify the 6 meter energy. The basic theory involved is the use of a variable-frequency oscillator whose output is *not* multiplied but is *added* to a high-frequency crystal oscillator.

This system greatly reduces the demands ordinarily made on a vfo for stability and drift. a 5 MHz oscillator, if multiplied to 50 MHz, suffers from the equal multiplication of drift, FM, hum, or other unwanted modulation, and other

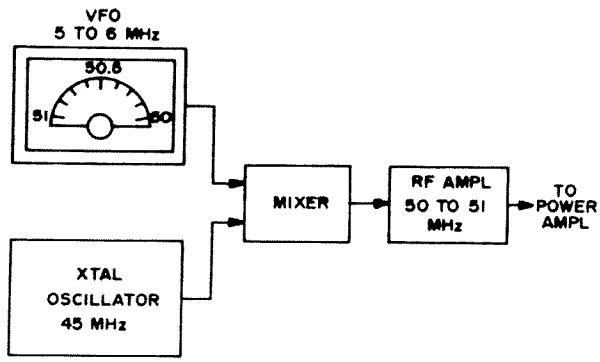

Fig. 1. 6 meter crystal-HET-vfo, block diagram.

undesired oscillator defects. A 5 MHz variable oscillator which is added to a crystal-controlled 45 MHz oscillator avoids this *multiplication* of instabilities.

When two oscillators with different frequencies are fed into a mixer, there are four frequencies always present in the collector circuit. These are F1, F2, F1 plus F2, and F1 minus F2. In the system being described here there will thus be present in the mixer collector 5 MHz, 40 MHz, 45 MHz, and 50 MHz. The mixer collector is of course tuned to 50 MHz, and subsequent amplifiers serve to reduce the other frequencies to an undetectable level at any reasonable distance from the antenna.

The emphasis is on selectivity, using a tuned amplifier to get the desired power output rather than pushing any one stage for maximum power, which is not generally coincident with maximum selectivity. Note the base and collector circuits, which are tapped down on their inductors. This matches their impedances to the proper point on the coils for sufficient power plus maximum selectivity.

In a spare-no-cost design, generally the criterion for military circuits, a balanced modulator is often used, but tests here show that a small number of tuned circuits following the mixer will prevent any detectable amount of undesired energy from reaching the antenna.

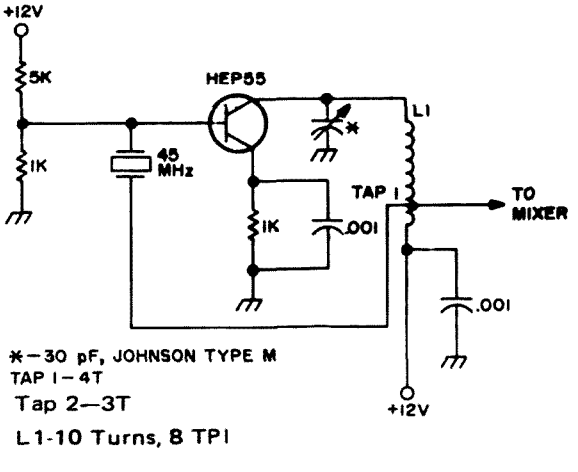
The Crystal Oscillator

The question of how much power output to try for here is important for several reasons. First, you would like to get as much power as possible in order to reduce the number of subsequent amplifiers. A famous (for its uniqueness) transmitter, I think pre-WW 2, used one Taylor tube as a crystal oscillator and only *one* more as a kilowatt CW rig! However, contrary to this example of exaggeration, most of today's crystal manufacturers say that a rock should be used only to control the generation of a *small* signal, and that power should be sought in following amplifiers.

Another item is the fact that VHF crystals will drift and/or jump if you try for too much power, as I well know from past experience. Any time that I used more than about 80V on tube oscillators, drift would set in, if not worse, such as jumps in power or frequency, and noise. Dc power of around 800 mW was involved, and if this is used as a criterion for solid state oscillators, we arrive at quite a few mils, using a 12V supply. A power region should be chosen which is not too far below the maximum for the crystal but which at the same time will assure its safety from drift. The way to find out is to try it, which I did, and the circuit shown works in fine style.

Referring again to the Old Days of tubes, a pilot light was often put in series with a crystal to check on the power and to act as a fuse. With today's VHF crystals this is not too feasible, unless some enterprising lads in the electric lamp business make some bulbs with a milliwatt or so of power. Also, as mentioned before, the crystal people are very disinclined to rate their crystals on power, so we're kind of on our own in this matter. The best place to regulate the power of both the crystal oscillator and the vfo, if you need to do so, is with the value of their emitter resistors.

The circuit is shown in Fig. 3. I checked once again both the regenerative and the degenerative feedback circuits and find that the degenerative circuit is more stable and produces more usable power output than the other. Note that if a capacitor is substituted for the crystal, *no* oscillation



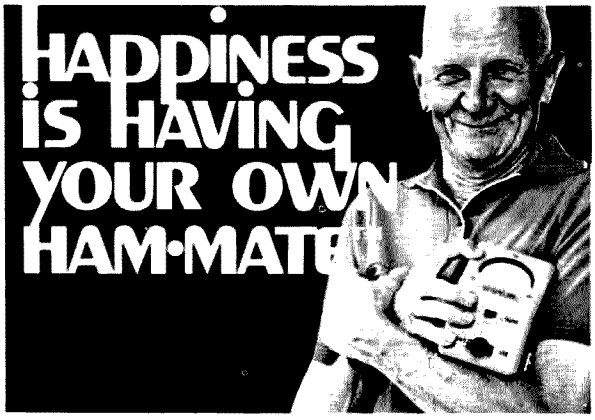


Fig. 3. Crystal oscillator, 45 MHz.

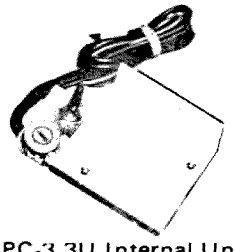
will occur. This is because the base is *in phase* with the collector and the emitter is

The New HAM-MATE™ Directional RF Wattmeter is a direct descendant of the famous model 43 THRULINE® – the professional standard of the industry. Designed specifically for the serious radio amateur, three models currently available measure forward and reflected power in the following ranges:



4350: 2000/200W, 1.8-30MHz (160 meters to 10 meters)
4351: 1000/200W, 1.8-30MHz (160 meters to 10 meters)
4352: 400/40W, 50-150MHz (6 meters, 2 meters)

All have an Insertion VSWR below 1.1 in 50-52 ohm lines, a minimum of 20dB Directivity, 8% Accuracy, SO-239 female UHF connectors and carry the 12 months guarantee of all Bird instruments.

out of phase with the collector; this is the circuit which is degenerative (also known as negative feedback). As a result of this, until the frequency of the crystal is reached with L1 and C1, no oscillations will occur. The crystal then reverses the phase and the system oscillates. I have mentioned this circuit many times and will probably do so in the future, as it really is sure fire for VHF work.

The Vfo

Here again we shouldn't try for maximum power but instead should check carefully for the power that can be obtained with complete safety against drift. If the transistor heats to any large degree, you can be sure you *will* have drift. There is a well-known complete rig on the market right now which does just that! Fortunately in the rig being described here, I not only keep the vfo at a power which does not heat it up, but I also have a circuit which does not multiply any remnant of instability which might not be economical to remove completely.

Figure 4 shows the oscillator as finally worked out and it is a good one. Reliance is placed on heavy capacitor padding, a standard method for stability but which does call for good capacitors.

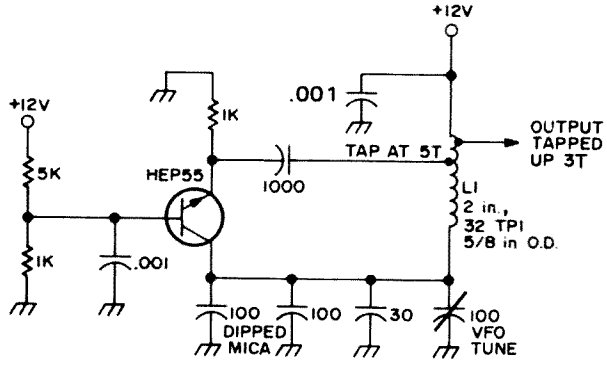

Fig. 4. 5 to 6 MHz vfo.

This unit is the heart of my future 6 meter transmitters, and probably will be for the two meter design as well, along with the Miller MD-4 dial, an automatic two-speed dial and very handy. Using the inductor, padding capacitors, and the 100 pF variable shown, the range tuned is from 50 to 51 MHz. That is, the actual vfo

oscillator runs at 5 to 6 MHz, and the final output from the mixer is 50 to 51 MHz. This is cutting things a shade too close, so add a few turns to L1, cut the padding down a little, and set up something like 49.9 to 51.1 MHz. As mentioned, you can also switch crystals, or get 2 MHz on the dial by increasing L1 still further and dropping down on the padding again. We're just indicating the method here.

The oscillator is very neat and clean and uses the "universal" transistor, the Motorola HEP55. Positive feed is assured by the base connection being out of phase with the collector. It is ac grounded, and the opposite end of the coil from the collector is also grounded. The emitter is tapped up on the coil from the ground end, which puts it in phase with the collector, for the proper relation. The number of turns of this tap up from the ground end controls the amount of feedback. Output is through a tap on L1 which goes over to the mixer base input.

Numerous additions can be considered, such as "battle-ship" construction for real tough mobile environments on boats, planes, etc. An interesting thought is a switch that cuts out the vfo and the crystal oscillator on 45 MHz and switches over to another crystal socket on the front panel for a straight-through crystal oscillator at your choice of fixed frequencies in the band, for nets and round tables. Just thinking out loud – I mean on paper.

As is, this 5 to 6 MHz vfo worked immediately and has given no trouble of any kind since then.

Preliminary calibration of the dial is made easier for beginners who may not have a collection of 50, 50.1, 50.5 and 51 MHz crystals on hand, by the presence on the air of WWV on 5MHz and Montreal, Canada on 6 MHz. This latter is a B.C. station but seems to be audible over most of the East Coast, and probably quite a way to the West. Zero-beating these stations with the calibration dial at 50 and 51 MHz can be easily done with your receiver. Once again, be *very* sure you are on 5 and 6 MHz, because of the possible occurrence of image and harmonic detection in your receiver. Once you have the 5 and 6 MHz logged, you can transfer the dial markings to 50 and 51 MHz. Remember that absorption wavemeter when you do this operation.

The Mixer

Figure 5 shows the circuit. It is not much different from a receiving mixer. The

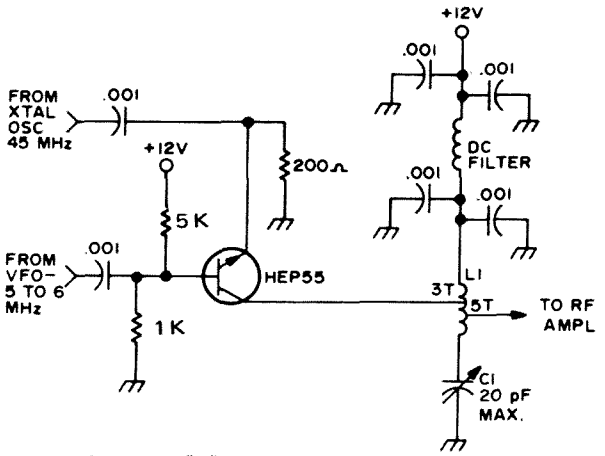

Fig. 5. Mixer, 6 meter-HET-vfo.

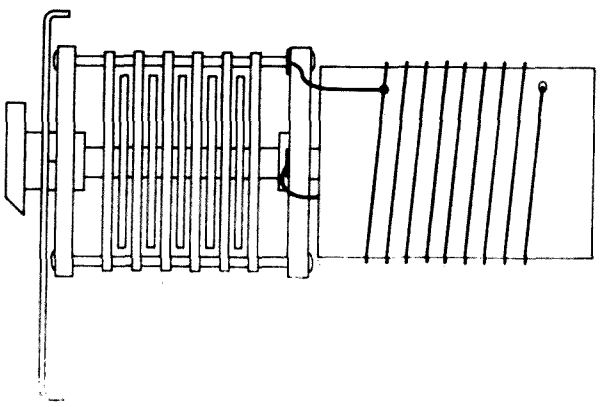
signal from the 5 to 6 MHz oscillator is brought in to the base, and the 45 MHz crystal oscillator is coupled to the emitter. Dc bias is furnished by the standard 5K and 1K resistors. The emitter has a 200Ω resistor to ground, which sets the operating point for best mixing.

The collector is tapped on to L1 only three turns up from ground, or cold end, which gives the best output for the 50 MHz beat note. Again, use that absorption wavemeter to check the mixer output. Figure 6



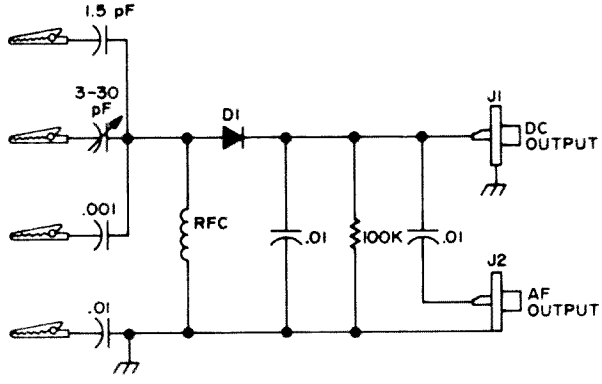


Fig. 6. Sketch, absorpotion wavemeter, James Millen type.

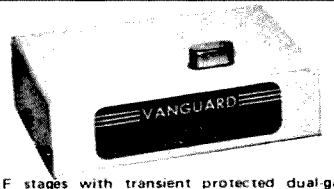
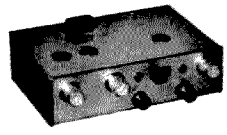


shows what such a device looks like, in the James Millen version, which is the best known. Remember those various outputs that are present in the mixer collector circuit as mentioned above. The 45 MHz energy in the collector can even have more power than the beat note on 50, so don't mistake it or try to use a receiver alone to identify these two outputs, unless it is of the TRF type, like my old favorite – the tuned diode receiver. You *can* use your receiver to listen to these various frequencies once you are *sure* the mixer output circuit is correctly lined up on 50 MHz.

I also listen on an *untuned* diode to note any spurious, squegging, discontinuous jumps in power or frequency, etc. This is a little diode "plank," made up as in Fig. 7. Note the variety of inputs to suit the various frequencies you may be monitoring. For UHF up into microwaves use the 1.5 pF. On VHF and UHF the 3 to 30 trimmer is good For lower frequencies the .001 capacitor delivers more rf to the diode for test purposes. The diode output also has more than one connection. With the alligator clips attached to your rf circuit under test you can thus measure gain with a microammeter plugged into the dc output jack, and listen to what is going on at the same time with a small af amplifier plugged into the audio jack. This can be really vital as you go up into the UHF region. RCA's excellent book, *Transistor and Diode Manual* has the following remarks on these subjects: "Various instabilities can occur in transistor frequency multiplier circuits, including low-frequency resonances, parametric oscillation, hyster-

SELECTED CONVERTERS AND RECEIVERS

40 dB GAIN 2.5–3.0 N.F. @ 150 MHz



2 RF stages with transient protected dual-gate MOSFETS give this converter the high gain and low noise you need for receiving very weak signals. The mixer stage is also a dual-gate MOSFET as it greatly reduces spurious mixing products – some by as much as 100 dB over that obtained with bipolar mixers. A bipolar oscillator using 3rd or 5th overtone plug-in crystals is followed by a harmonic bandpass filter, and where necessary an additional amplifier is used to assure the correct amount of drive to the mixer. Available in your choice of input frequencies from 5–350 MHz and with any output you choose within this range. The usable bandwidth is approx. 3% of the input frequency with a maximum of 4 MHz. Wider bandwidths are available on special order. Although any frequency combination is possible (including converting up) best results are obtained if you choose an output frequency not more than 1/3 or less than 1/20 of the input frequency. Enclosed in a 4-3/8" x 3" x 1-1/4" aluminum case with BNC receptacles, power and antenna transfer switch. Thousands of our converters are now in use by satisfied customers, many of whom are government agencies and universities.

Model 407 price: 5–200 MHz $42.95
201–350 MHz $44.95

Prices include .005% crystal. Additional crystals $5.95 ea.

UHF 20 dB MIN. GAIN 3 to 5 dB MAX. N.F.

This model is similar in appearance to our Model 407 but uses 2 low noise J FETS in our specially designed RF stage which is tuned with high-Q miniature trimmers. The mixer is a special dual-gate MOSFET made by RCA to meet our requirements. The oscillator uses 5th overtone crystals to reduce spurious responses and make possible fewer multipliers in the oscillator chain which uses 1200 MHz bipolars for maximum efficiency. Available with your choice of input frequencies from 300–475 MHz and output frequencies from 14–220 MHz. Usable bandwidth is about 1% of the input frequency but can be easily retuned to cover more. This model is now in use in many sophisticated applications such as a component of a communications link for rocket launchings.

Model 408 price: $51.95
.005% crystal included

VHF FM RECEIVER
11 CHANNELS • 135–250 MHz

● 11 crystal-controlled channels. ● Available in your choice of frequencies from 135–250 MHz wide. ● I.F. bandwidth (channel selectivity) available in your choice of +/–7.5 kHz or +/–15 kHz ● 8-pole quartz filter and a 4-pole ceramic filter gives more than 80 dB rejection at 2X channel bandwidth. ● Frequency trimmers for each crystal. ● 2 to 3 μvolt for 20 dB quieting. ● Dual-gate MOSFETS and integrated circuits. ● Self-contained speaker and external speaker jack. ● Mobile mount and tilt stand. ● Anodized alum. case, 6" x 7" x 1-3/8"

Model FMR-250-11 price: 135-180 MHz $109.95
181-250 MHz $119.95

Price includes one .001% crystal. Additional crystals $6.95 ea.

HOW TO ORDER:

All the preamps on this page are available only from Vanguard Labs. For receivers and converters, state model, input and output frequencies and bandwidth where applicable. Remit in full, including sales tax if you reside in New York State, direct to Vanguard Labs. Prices include postage by regular parcel post. For air mail or special delivery include extra amount; excess will be refunded. Send money order or certified check for faster shipment.

VANGUARD LABS 196–23 JAMAICA AVE. HOLLIS, N.Y. 11423

esis, and high frequency resonance." Hysteresis refers to "discontinuous mode jumps in output power when the input power or frequency is increased or decreased." So don't be downhearted if you find troubles in your solid-state building projects. You're not alone!

There will be more of this cautionary material, so keep reading, and try to understand what I mean by "smooth tuning." You really need it with solid state devices.

When everything is working right, the mixer collector or circuit *does* tune easily without those discontinuous jumps. But watch out for that 45 MHz which is just a little up on the mixer capacitor knob from the 50 MHz point.

Expect in the neighborhood of 10 mW output from the mixer.

The RF Amplifier

Refer to Fig. 8 for the schematic. This one adjusts fairly easily once you get the base input capacitor adjusted to the right value. Start with a small amount and increase it a little at a time. The collector

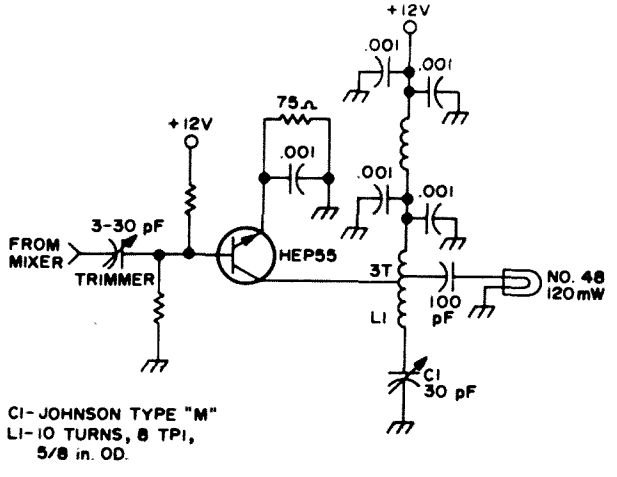


Fig. 8. Rf stage, 6 meter-HET-vfo.

tap should then be adjusted to the proper place and C1 tuned to 50 MHz. The collector tap can be left at three turns from the cold end if you do not wish to check it yourself, as it is not too critical. The No. 48 rf output test bulb is critical as to match though, as you will see.

Due to the normal internal feedback of transistors this stage can oscillate easily, so start with the input capacity at a small value, keep tuning both the mixer collector and the rf stage collector, and push the power up gradually with a temporary pot of 500 or 1000Ω in the emitter in series with the 75Ω shown. If everything is right you will find 50 MHz output when the collector circuit is coupled to a tuned diode detector. Keep increasing C1 until you come to the condition where self-oscillation occurs, then back off a little. The tap on the mixer coil can also be reduced from 5 turns above ground to a lower number at first. As it is now, in final adjustment, both circuits tune nicely without oscillation and are not critical.

This stage can be modulated in the usual manner, but I advise a Motorola HEP75 with a dissipation of *three* watts and a cut-off frequency of 800 MHz as a following stage. It puts out 600 mW on 432 MHz so you can expect at least a watt or so on 6.

Breadboard Layout

Figure 9 shows the layout exactly as built up here, and working fine. There is plenty of room for changing all the values

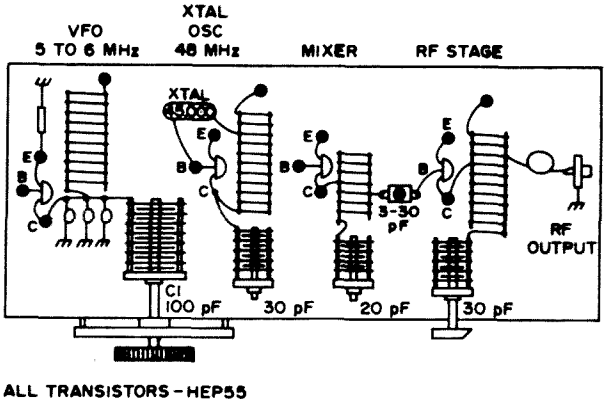

Fig. 9. Breadboard layout, 6 meter-HET-vfo.

as needed, testing transistors, and selecting another set of components for packaging in a minibox. The ground plane works as it should, with no ground-loop currents noticed so far. You can see the four separate stages on the breadboard and check out the individual operation of each stage by itself if you need to. Their packaging in a small box should not be difficult providing a little shielding is used correctly. Of course, nothing stops you from putting this one on the air as is.

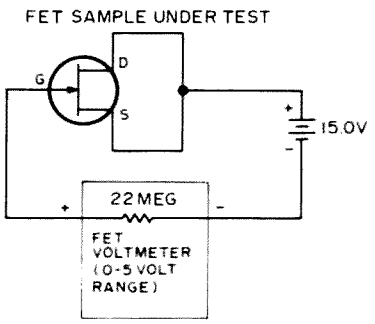
THE FET VOLTMETER AS A NANO-AMPERE METER

The Field-Effect Transistor voltmeter, an instrument which has an imput impedance of 22MΩ on all ranges with a full-scale deflection of 0.5V on the most sensitive range, is an extremely useful device and one that all hams should build. An added application of this instrument is as a nano-amp meter for measuring the gate-to-channel leakage of individual FET samples. This leakage current (called I_{GSS}) is quoted on the manufacturers' specification sheet as being 2 mA maximum for the 2N3819 and 20 mA maximum for the 2N3820 with 15V applied. This small current is just about impossible to measure using the usual selection of ham test equipment.

The I_{GSS} of a FET sample can be measured directly by using a 15V dc source and a K3LCU FET voltmeter. The circuit diagram shows the hook-up. The source and drain are connected and in effect the gate-channel junction is being tested as a reverse-biased diode.



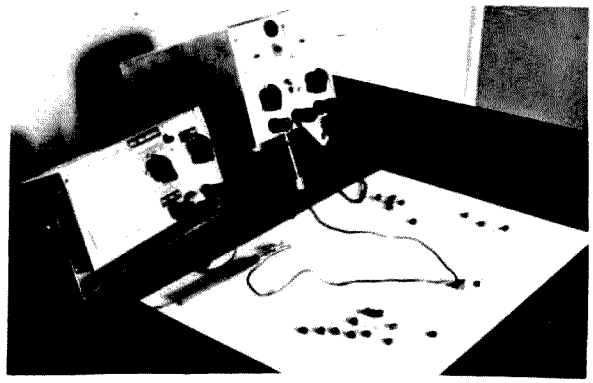


Diagram: The circuit of the I_{GSS} test. Note that the FET voltmeter is set to the 0.5V range and reads as 22.72 nano-amps full-scale. Polarities shown are correct for an N-channel device. If P-channel devices are to be tested then the supply connections and the meter connections must be reversed. This is most easily done by reversing the transistor socket connections.

The photograph shows my version of the K3LCU meter (see *73* July 1966 issue) – one of the handiest instruments I have ever built – and a home-built regulated low-voltage power supply. I have a transistor socket with suitable leads attached that I keep for this I_{GSS} measurement. The FETs are plugged into this socket and the I_{GSS} is shown on the FET voltmeter. I_{GSS} is temperature-sensitive so the reading depends upon the applied voltage and the junction temperature as well as the quality of the device junction. In practice, faulty FETs are very quickly sorted out.

The full-scale reading on the FET voltmeter is really the current corresponding to 0.5V applied across 22MΩ. This works out at 22.72 nano-amps. For the 1.0V range on the FET voltmeter, the full-scale represents twice this current (45.44 mA).

This test will help to sift out the good ones from the surplus FETs now available.

TIME/FREQUENCY MEASURING SYSTEM

PART I
system concepts

This is the first of a three-part series describing the component parts of a time/frequency measuring system for a well equipped amateur radio station and workshop. The goal is to obtain an accurate station clock and frequency counter which can be calibrated by the amateur in his own shop; the reasons for organizing the system as it is are given in the following paragraphs.

Two pieces of equipment are used: the GMT clock/time base, described in this month's article, and a 220 MHz frequency counter to be described in Parts II and III. Each of these items is useful by itself, but they are intended to work together as shown in the system block diagram, Fig. 1. This system will provide the amateur with a time and frequency measuring system which he can maintain accurately to better than one

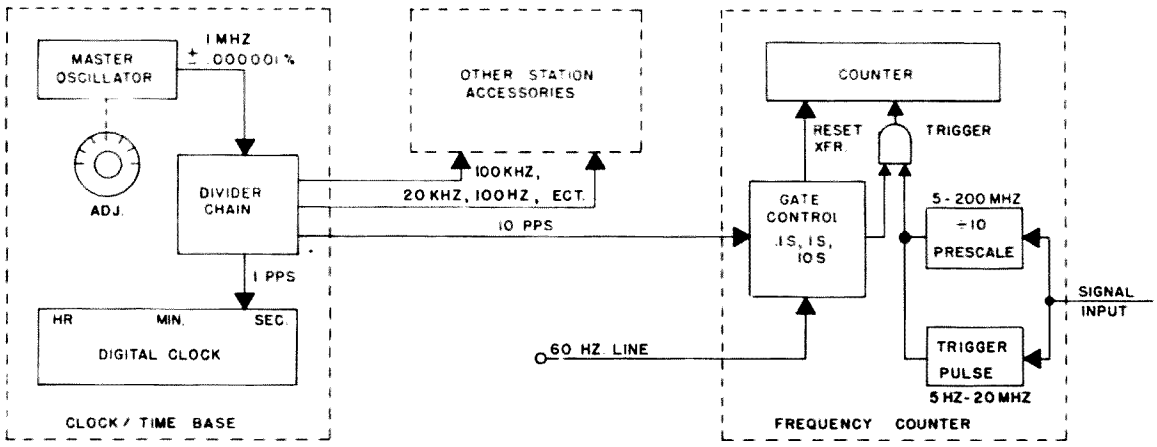

Fig. 1. System block diagram.

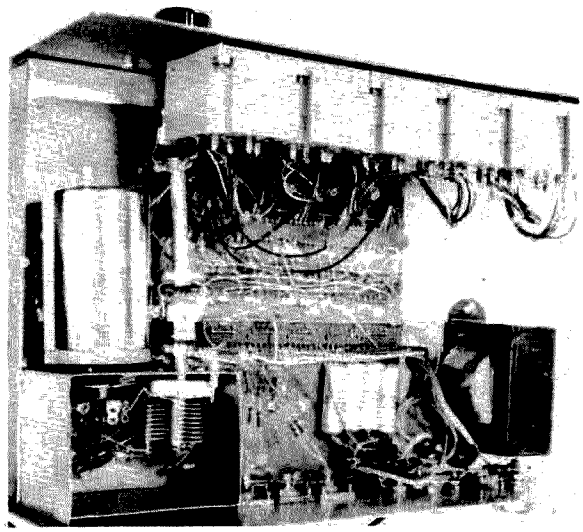
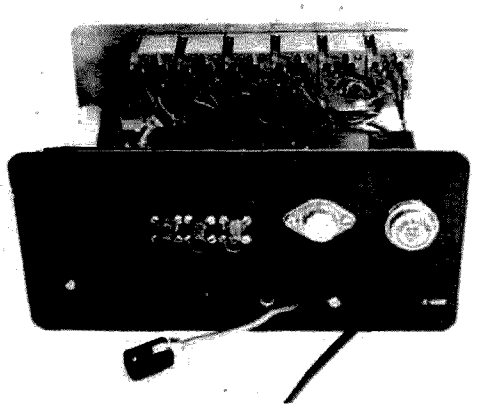
part in 10^6 (.0001%) with only a WWV receiver and a little patience.

There is no need to elaborate on the usefulness of a frequency counter, as it is fairly well recognized. This counter is different from most others in that it works to 220 MHz and has a different approach to the time base. The counter is intended to be used with the companion time base to get the specified accuracy, but has provision to use the power line for a reference with reduced accuracy (.01%) for use away from the home shop.



The 6½ digit counter features a Schmitt trigger, narrow pulse generator, and 10 second gate for accuracy at very low frequencies, a 1 second gate for low and medium frequencies, a 0.1 second gate (with kHz decimal point) for high frequencies, and a divide-by-ten prescaler for VHF. A decimal point is automatically set in the display to agree with the switch setting. A latching storage register is used to give a steady display as in all modern counters. Most circuitry is transistor-transistor logic (TTL) integrated circui (IC), with some discrete transistors in the trigger/pulse amplifier.



The clock is a 24-hour digital with hours, minutes, and seconds readouts, and also can be used to run remote slave readouts. All circuitry is IC, mostly TTL. The time base is a crystal oscillator with oven, followed by a divider chain to derive the specific trigger periods needed by the rest of the system. A battery power backup is used to prevent losing clock timing in case of ac power interruptions.

Besides the frequency counter, there are other uses for precision frequencies: VFO calibrators, phase-lock loop synthesizers, crystal substitutes, oscilloscope markers, etc. One station time base can run all of these.

Accurate Home Calibration

The clock is combined with the time base to provide a monitor on the accuracy of the time base, allowing the amateur to perform his own very accurate calibration. One part in 10^6 is 0.6 seconds per week, so weekly checks on the drift of the clock versus WWV provide a means for gradually getting the time base oscillator "right on." After several months of occasional adjustments I have achieved a drift rate of less than 0.1 second per month in my own unit, which is better than one part in 10^7 (.00001%).

The time drift calibration method may seem a little tedious, requiring several weeks to months to achieve good calibration. There is actually very little to it, however. In my case, I spend about five minutes every Sunday morning listening to the one-second ticks on WWV and comparing them to the time changes on the clock. When the clock shows drift of more than 1/4 second from the previous week, I adjust the oscillator vernier control slightly in the direction to reduce the error, reset the clock to synchronize with the ticks, and wait another week. Many weeks go by with no adjustment required at all. If I miss a week, I just double the allowance for the next week.

It may occur to some (who haven't tried it) that one could calibrate an oscillator to any desired degree of accuracy by zeroing harmonics of the oscillator's output against the WWV carrier. This has been the classic method for many years of checking HF radio calibration with the 100 kHz crystal calibrator. This works fine as long as one is shooting for accuracy no better than one part in 10^4 (1.4 kHz on 20 meters for example). That is OK for 20m, but you will never net a 2 meter FM rig with measurements that crude! It may come as a surprise to some that the WWV carrier, as received in most locations, is not accurate to better than one part in 10^7 because of doppler shift in the skywave reflection from the ionosphere, which is constantly moving. The different techniques used to check zero-beat against the carrier degrade accuracy further; an audio beat for example is very poor, being no better than 10 Hz on a 10 MHz signal, or one part in 10^6, and usually worse. Some more exotic methods may introduce less error, but the ultimate limitation of the WWV signal itself still limits the accuracy to less than that needed to check a modern, state-of-the-art time base for a counter.

The 20 kHz VLF signal put out by WWVL is not subject to the doppler errors of the HF signals, and therefore is the frequency reference signal used by most laboratories requiring precise frequency calibrations. To use this signal, however, requires a VLF receiver and phase comparator, which is more equipment to build.

On Picking Frequency Tolerances

The reason for picking one part in 10^6 as being the minimum accuracy to shoot for in a counter design is that current VHF frequency tolerances (and VHF is where you *really* need a counter) require radios to be set to .0005%, or 5 parts in 10^6.

A device to measure this frequency must be significantly better than this, so one part in 10^6 is a worst case. As a related matter, the readout capability of the counter should be compatible with the accuracy of the instrument. In other words, a counter with an accuracy of one count out of one million (10^6) should have a six-digit readout. Any less than this, and the full capability of the counter is not being used. Any more, and the user is kidding himself by reading meaningless numbers. For instance, I could have built a nine-digit counter and thus be able to read 220 MHz to the nearest cycle, but this is better than one part in 10^8, and the last two digits would be unreliable. Something like "measuring with a micrometer and marking with chalk." This same rebuttal applies to those who argue that they don't like prescalers because they can't read the frequency to one cycle!

I chose to make the counter/time base and the counter in separate units, because I use the counter/time base as an accessory with my HF rig; that's where I want the clock and that's where the WWV receiver is, while the counter stays across the room at the work bench. The two units are connected by one coax cable. A builder could economize by putting both units in one cabinet to share a power supply, decoders, and readouts.

ACTIVE FILTER DESIGN AND USE PART IV

In the previous parts of this series on active filters we have converted LC passive filters to active RC transistor filters and integrated circuit designs to active RC transistor filters and integrated circuit designs with external frequency compensation. Although all common types of filters were covered, design emphasis was placed on filters in the low or audio range of frequencies where bulky inductors tend to become both inefficient and unwieldy. However, the same principles can be applied to higher frequency filters and in this last part we will design a number of active filters in the high frequency range in addition to some circuits that should prove useful to the amateur.

As the frequency of interest rises, active filters utilizing RC networks tend to become progressively less efficient. In an attempt to maintain a satisfactory component value ratio, and still maintain reasonable Q, the resistors of the twin-T configuration are reduced in value only as much as necessary to allow the corresponding capacitors to fall in the low picofarad range. Such sacrifices reduce the usefulness of the twin-T above ultrasonic frequencies to relatively wide bandpass amplifiers and other requirements where bandwidth/attenuation values are not too low. Figure 1 shows a circuit designed around the RCA CA3035 linear integrated circuit amplifier and a twin-T network. At a frequency of 455 kHz, the component values of the network have dropped to a point where Q becomes a problem. However, the circuit is still useful as a buffer amplifier to follow a local oscillator stage, or give low attenuation over a medium range such as might be desired in the first i-f of a scanning receiver. Capacitors C5 and C6 act only as dc blocking capacitors. Varying R4 will provide a slight change in center frequency and Q The response of the circuit is shown in Fig. 2. Increasing the value of R1 will increase Q, but at the expense of gain. The curves of Fig. 2 show the response with both 120 kΩ and 270 kΩ resistors at R1.

In Fig. 3, a variation of the twin-T notch allows the active filter to be tuned over a 10:1 range. Resistor R1 again affects Q and

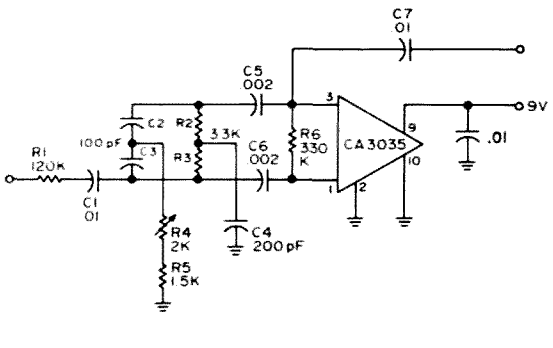

Fig. 1. 455 KHz bufferamp/filter.

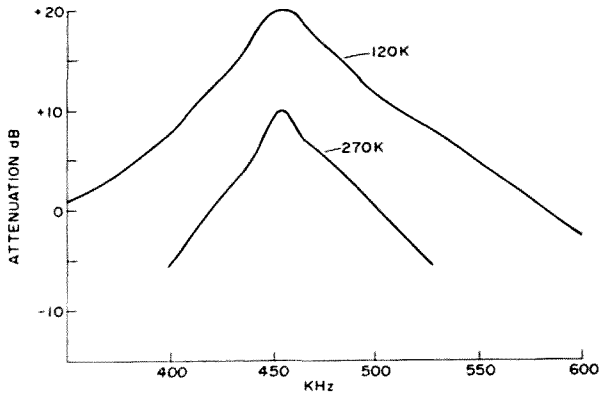

Fig. 2. 455 KHz bufferamp/filter response.

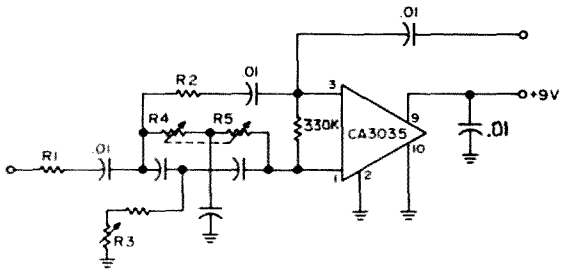

Fig. 3. Variable notch filter.

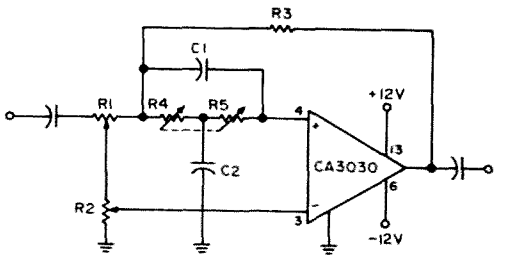

Fig. 4. Deep notch filter w/variable Q, frequency.

gain while R3 fine tunes Q. Ganged variable resistors R4 and R5 control the frequency of the notch while resistor R2 limits feedback.

Carrying the design of Fig. 3 further yields the configuration shown in Fig. 4. This deep notch filter may be varied in both Q and frequency. Using an operational amplifier as the active element allows differential operation of the amplifier to assure high attenuation of the notch frequency. The input signal is fed to the positive terminal, while a portion of the input signal combined with feedback from resistor R3 is fed to the negative input terminal. By adjusting R2 so that both inputs are equal, the output becomes zero, producing infinite attenuation at the notch frequency. This notch frequency can be varied over a 10:1 range by resistors R4 and R5. Varying resistor R1 alters the circuit Q allowing the width of the notch to be adjusted. Capacitors C1 and C2 are of the same value and may be determined by the formula for the capacitor bridge section of the twin-T net-

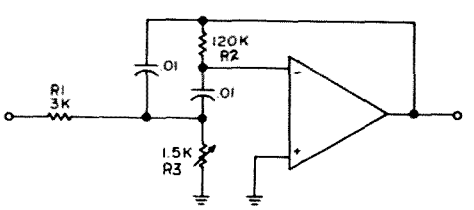

Fig. 5. Variable bandpass filter.

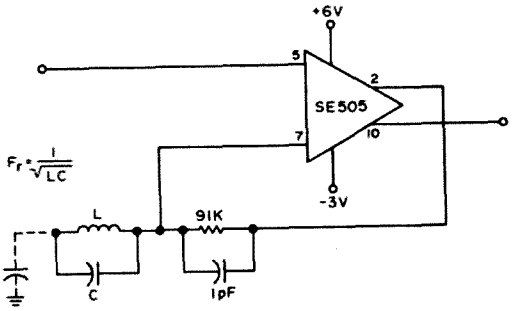

Fig. 6. Band reject amplifier.

work discussed in an earlier part of this series.

An active bandpass filter which can be varied in frequency, without affecting the bandwidth or gain, is shown in Fig. 5. The center frequency is controlled by resistor R3 while retaining a constant bandwidth of about 260 Hz. The component values shown will produce a bandpass response centering close to 2 kHz, with more than 26 dB gain. To design for a frequency of your choice, choose a convenient value for the capacitors, the desired gain and bandwidth, and plug these values into the following formulas:

$$R_1 = \frac{1}{2\pi BcGC}$$

$$R_2 = \frac{1}{\pi BwC}$$

$$R_3 = \sqrt{\frac{1}{2\pi C[(2f2/Bw) - BwG]}}$$

As with other active filters, this type may

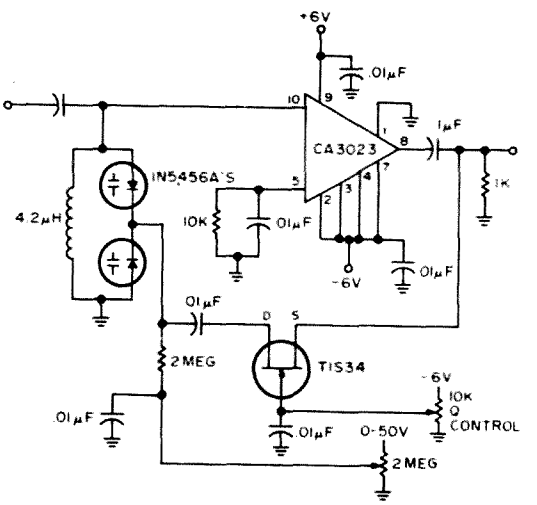

Fig. 7. Tunable i-f amplifier w/variable Q.

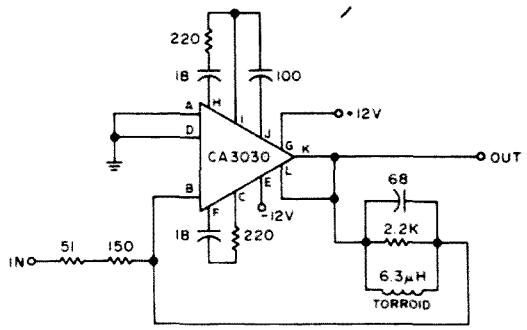

Fig. 8. 10 MHz bandpass amlifier.

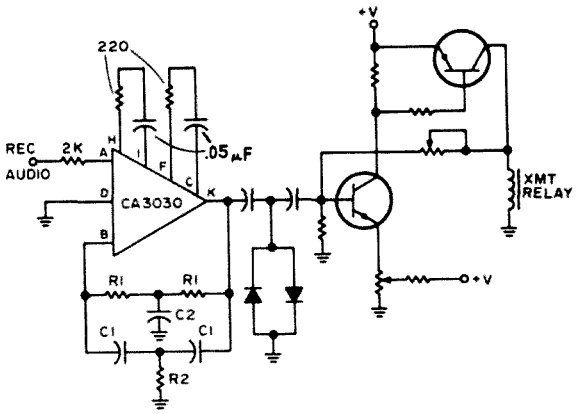

Fig. 10. Tone decoder filter.

also be cascaded and the individual filters tuned to different frequencies to provide a variable comb effect.

Active filters at radio frequencies require integrated circuits with the necessary frequency response and the return to inductors, although of a more convenient size. Figure 6 shows a band reject amplifier utilizing a Signetics differential amplifier. Good Q can be obtained, where wide response is not a requirement, by using torroid cores for winding the coils. By changing the position of C to that shown in the dashed line, the circuit becomes a bandpass amplifier. The Signetics integrated circuit has a bandwidth dependent upon power supply voltage, approximately 10 MHz for the voltages shown in Fig. 6, and may be pushed to 30 MHz with a maximum total voltage supply of 12 volts (+9 and -3 volts, etc.).

Every ham has, at one time or another, wished he could tune his receiver i-f off frequency slightly and/or increase i-f gain to get rid of interference. The novel circuit shown in Fig. 7 will do both, and when used with a high frequency integrated circuit, will provide a tunable rf amplifier. The values shown give a tunable response at about 10.7 MHz. The RCA CA3023 integrated circuit amplifier provides gain to 30 MHz. The field effect transistor acts as a variable resistance of the tuned circuit network and thus the input resistance of the amplifier. A change in the amount of feedback, or load resistance, will affect the Q of the tuned circuit. An increase in circuit Q of more than 2000 is possible while tuning control places the highest gain of the response at the desired frequency.

An RLC bandpass amplifier, utilizing the RCA CA3030 integrated circuit, is shown in Fig. 8. This amplifier will provide a gain of 20 dB at a center frequency of 10 MHz with a 3 dB response of about 1 MHz, as shown in Fig. 9. The effective Q of this circuit works out to be about 10.

Tone signaling and decoding circuitry can be greatly simplified by incorporating operational amplifiers as filter amplifiers. Use of the twin-T design is shown in Fig. 10. Values for the twin-T network are determined according to the following formulas:

$$R_1 = 2R2$$

$$C1 = \tfrac{1}{2}C_2$$

$$f_o = \frac{1}{2\pi R_1 C_1}$$

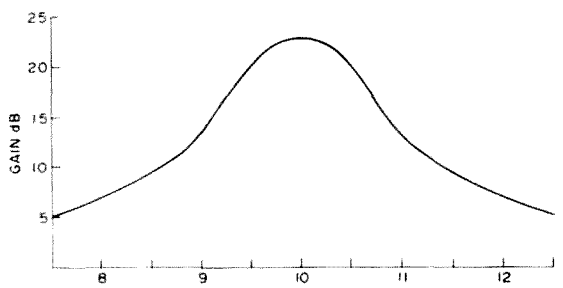

Fig. 9. 10 MHz bandpass response (w/o toroid).

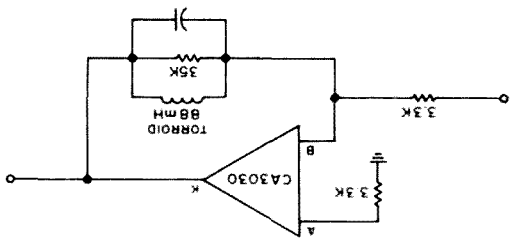

Fig. 11. LC circuit for tone decoder filter.

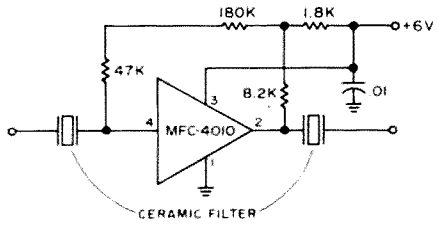

Fig. 12. 455 kHz i-f amplifier.

If you have a few 88 mH torroids in your parts box, the circuit of Fig. 11 can be used. This configuration shows the operational amplifier in an inverted mode, the only design which will produce a true single tuned response. Circuit Q here approaches 33 with a gain of more than 20 dB. In multiple frequency decoders, different tuned amplifiers may be paralleled with the necessary switching circuitry to provide coded entry into a repeater system.

Integrated circuits can also be used with ceramic or crystal elements as frequency components. The circuit of Fig. 12 gives 70 dB gain at a frequency of 455 kHz. Due to the fact that more gain is available from integrated circuits as compared to discrete components, impedances are easier to match without worrying about insertion loss or distorted responses.

Although single resonant circuits coupled with a linear or operational integrated circuit cannot be expected to provide narrow band responses at higher frequencies, they are useful as preamps or in other areas where a wider response curve can be used. Offering more than 20 dB gain, the circuit shown in Fig. 13 is designed for 20 meters where the 3 dB points of the response are less than

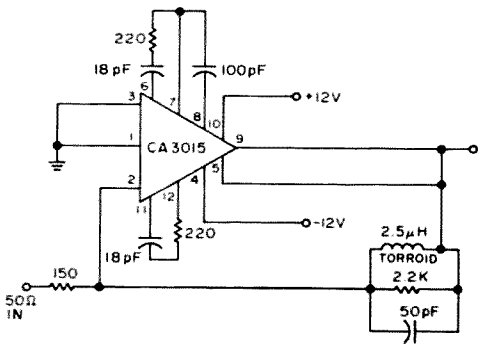

Fig. 13. 14 MHz amplifier.

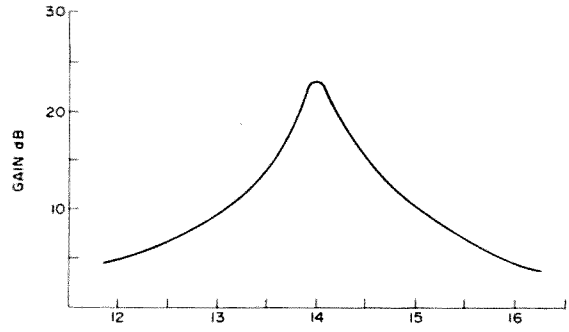

Fig. 14. Response curve of 14 MHz amplifier.

1 MHz wide. Figure 14 shows the response of the 14 MHz amplifier.

By the time you read this article, there will have been new advances in integrated circuit fabrication and design. However, the basic design methods will remain the same. We will probably see integrated circuits with greater available gain without the probability of feedback and possibly circuitry incorporating inductors and capacitors which can be changed in value by application of external control voltage.

For those interested in pursuing the subject of active filters further, I recommend, in addition to the article references, the newly published book *Active Inductorless Filters*, edited by Sanjit K. Mitra. It can be obtained through the IEEE, 345 E 47th Street, New York, NY 10017, at $7.50 for members and $9.95 for non-members.

TRANSMISSION-LIMIT TIMER for REPEATERS

The ARRL won't be issuing Ragchew certificates to your repeater users, but then you won't be replacing finals every other day either.

A repeater should think for itself! It makes sense if you really consider it. The thing sits by itself all day every day (and night, too), spewing out whatever anyone wants to put into it. The only brain it has is the one owned by the body who sits at the business end of a control link. How much of a relief it would be to the control operator if the repeater itself could do most of the active monitoring – reducing his duty to not much more than keeping an ear tuned for dirty words.

The kind of brain every repeater really needs is actually quite simple. Primarily, it must limit the length of the repeater transmitter's "on" time. When a relay gets stuck shut, the "brain" would sense the problem and cut off the transmitter. When the local clown decides to play music through your system, or send endless Teletype signals through it, he won't be able to do it for long because the "brain" will know, and it will shut the repeater down for the duration of the attack. When a mobile operator sets his mike down on the seat and sits on the push-to-talk switch (it happens all the time!), the brain will put up with it for a minute or so – but if the anomaly persists, the brain cuts off the output of the big machine. When a long-winded operator ties up the repeater with another of his drawn-out ragchewing dissertations, you don't have to worry about hurting his feelings by telling him about it. Let the brain cut him out – automatically; he'll soon learn to keep his transmissions short, giving others a chance to use that fantastic communications system up there on the hill .

The Circuit

The timer circuit shown in Fig. 1 is the brain; it's ideal for just about all your repeater's timed operations because it is highly reliable on the one hand, and it is adjustable over a very broad period range on

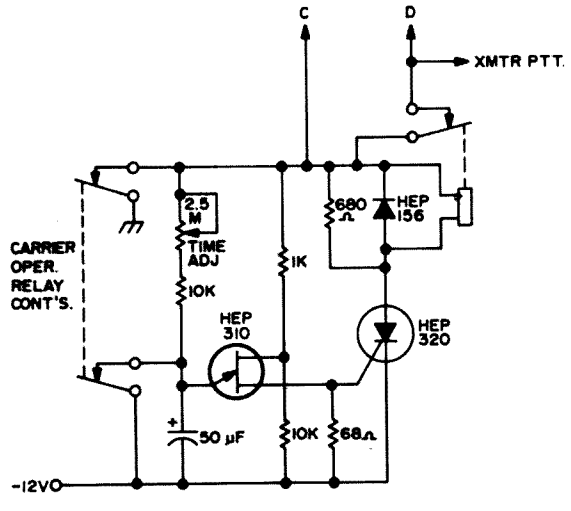

Fig. 1. This timer circuit is ideal for repeater applications because its period can be adjusted to any duration from 2 seconds to 4½ minutes. The top set of COR contracts starts the timed sequence and the lower set, on closing, resets the circuit. The relay is a Potter-Brumfield RS5D with a 6V coil having a resistance of 335Ω. Other relays can be used but the coil resistance must be no lower than that of the RS5D.

the other. It can be set for a period as short as 2 seconds, or as long as 4½ minutes. For a transmission-limit device, you'll probably want to set it for no more than 2 minutes at the most. It won't take the users long to cut their transmissions to less than that, you'll find.

The circuit shown employs a 6V dc relay with a coil resistance of 335Ω. Use of a relay with less resistance could cause excessive current, resulting in possible thermal destruction of semiconductors in the circuit. Just about any high-resistance relay will work in the circuit, though. The only precaution you should observe – other than that related to coil resistance – is to make sure that the relay contacts will be capable of handling the current load in the push-to-talk circuit. The contact rating of the RS5D is 2A; if your requirements exceed this value, the relay shown can be used to switch another relay with higher current-handling capability. Or, as an alternative, you can switch a circuit other than the push-to-talk line. The relay contacts, for example, can be used to remove B+ from the transmitter driver stages or the final amplifier. The idea, of course, is simply to get the transmitter off the air after the timed period.

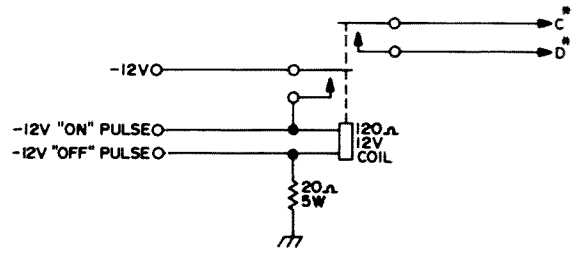
When the relay is switched off, the coil's collapsing field will cause a very high voltage spike to be induced in the circuit – as most hams who have worked with semiconductors have learned in dismay. This spike can easily destroy many types of semiconductors; so avoid problems by placing the HEP 156 diode across the relay coil as shown. The diode provides a discharge path for voltage spikes, thus insuring against wipeout of your semiconductors. And be particularly careful not to get the diode installed backwards, too – or the circuit current will be shunted around the relay coil, creating another very real threat to semiconductor devices.

How It Works

When a signal appears at the receiver, the A set of contacts on the carrier-operated relay (Fig. 1) close and the B set opens, thus starting the timed operation. At the end of the period, if the COR contacts are still actuated by an incoming carrier, the P-B RS5D relay will put in, removing the push-to-talk signal from the repeater transmitter. As long as the carrier is on the channel after this point, the relay keeps the transmitter off the air. When the carrier finally drops out, though, the B set of contacts resets the timer and the A set removes the operational voltage. And the whole sequence is ready to begin anew.

Timer Defeat Circuit

If your repeater is subject to abuse from channel jokers, you might want to incorporate a separate reset system in your own UHF control link. This precludes the pos-



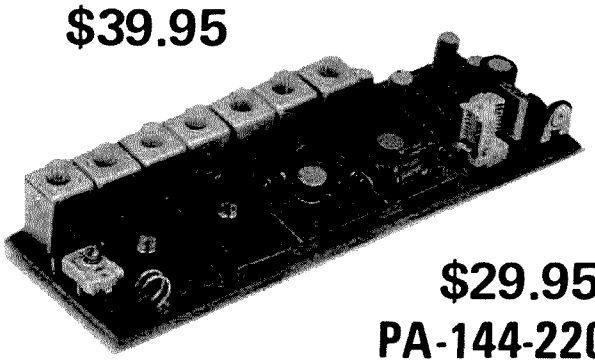


Fig. 2. Controlled timer "defeat" circuit. A momentary voltage pulse at the "on" point pulls in the relay and defeats the timer. A momentary pulse at "off" point returns the repeater to timed control.

sibility of some clown placing an endless carrier on the repeater input frequency just to keep your repeater shut down.

Figure 2 shows one satisfactory method for bypassing the timer from the control point. The control contacts should be installed across points C and D of Fig. 1, as shown.

The resistor in the defeat circuit will act as a voltage-dropping device, so you have to select a value that will not reduce the voltage on the relay below its critical pull-in point. Most low-cost 12V dc relays will put in with 10V, though, so you can probably use that figure as a logical starting point. If the coil resistance of the relay is about 120Ω (current drain of 100 mA), you should use a resistor of about 20Ω. This cuts the voltage to just under 11V, which should easily give rapid pull-in.

When the "on" pulse actuates the relay, the lower set of contacts (Fig. 2) applies a constant voltage to the coil to keep the relay latched in its energized state. But when a −12V "off" pulse is applied at the coil-resistor terminal, the potential across the relay coil is cut to zero, since both coil terminals are being fed with the same voltage. However, for the brief period of the "off" pulse, the resistor must dissipate the full power of the 12V signal; therefore, the resistor should be of sufficient wattage to handle that high-power surge.

If the values are as shown in Fig. 2, the resistor will be dissipating just over 7W during application of the "off" pulse. A 5W resistor should easily handle that, though, considering the fact that the signal is only applied for perhaps a fraction of a second (depending on your individual control scheme, of course).

Semiconductors

The unijunction transistor, diode, and thyristor (SCR) are all Motorola devices . . . (Why not? The timer circuit itself was provided by Motorola's design engineers!) These devices are available from *Circuit Specialists, Inc., Box 3047, Scottsdale, Arizona.* The other goodies should come from your junkbox or the local electronics supplier. . . .K6MVH

EXTRA CLASS LICENSE STUDY GUIDE

Questions & Answers Part III

46. What is the vacuum tube counterpart of a (1) grounded base circuit; (2) grounded emitter circuit; (3) grounded collector circuit?

A. (1) the grounded-grid circuit; (2) the conventional grounded-cathode circuit; (3) the cathode follower.

47. What useful functions does a balanced modulator perform in a radio transmitter?

A. None, except in a SSB or DSB transmitter. The function of the balanced modulator is to simultaneously provide amplitude modulation and carrier suppression. In a DSB or SSB transmitter, it eliminates the carrier.

48. How does the directivity of an unterminated "V" antenna and parasitic beam antenna compare?

A. The unterminated "V" is bidirectional, with its major lobes extending in both directions along the line which bisects the angle of the "V." The parasitic beam is unidirectional, with its major lobe extending in the direction toward the director (away from the reflector). Both designs also have a number of minor lobes which are ignored in this discussion.

49. If a crystal lattice bandpass filter has bandwidths of 3 kc/s at the 60 dB points and 1.5 kc/s at the 6 dB points, calculate the shape factor. At what frequency is the best shape factor achieved in a crystal lattice filter?

A. "Shape factor" is defined only for two specific levels of attenuation; in this problem, the only shape factor which may be calculated is the 6–60 dB shape factor, which is 2.0 (3 kc/s divided by 1.5 kc/s, or the wider passband divided by the narrower).

50. What would happen if the grid-bias supply of a Class C modulated amplifier was suddenly short-circuited?

A. The results would depend upon the design of the modulated amplifier. If it followed good design practice and obtained a major portion of its operating bias from a grid leak, the effects might be unnoticeable. If all bias were obtained from the bias supply (which would be poor design in the first place, tending to produce poor modulation) the amplifier's plate and screen (if any) currents would soar, probably damaging the equipment. In between these extremes, output and efficiency would probably drop, and modulation suffer.

Of course, any protective fusing on the bias supply would let go – and in the absence of fuses, portions of the bias supply itself would probably be destroyed or severely damaged.

51. How do trimmer and padder capacitors affect the low and high frequencies in receiver tuning?

A. Trimmer capacitors establish the minimum capacitance in a circuit, and padders establish the maximum capacitance values. Thus the trimmer capacitors determine the highest frequency to which a circuit may be tuned, and the padders determine the lowest frequency. In normal receiver practice, the coil inductance is adjusted to establish the lowest frequency, and the padder capacitors are then used to "track" the oscillator and rf circuits (which must tune to frequencies separated by the i-f, and should maintain constant frequency separation at all points in the tuning range – an impossible task). Trimmer and padder adjustments interact rather seriously with each other, and the

proper procedure calls for adjustment of the low frequency portion of the range first, followed by adjustment at the higher frequencies, and touch-up of the lows. The process continues circularly in this fashion until operation is satisfactory at all points in the tuning range.

52. What is the phase relation between the input and output signals in the common-emitter, common-base, and common-collector transistor circuits?

A. In the common-emitter circuit, output signals are 180 degrees reversed in phase from input signals. In the other two configurations, output and input signals are in phase with each other.

53. How can a transmitter be tested for self oscillation? What precautions should be observed during testing?

A. The transmitter is tested for self oscillation by first operating each amplifier stage individually (in the absence of any driving signal) at normal operating levels, tuning all adjustments of each stage through their normal range, and determining that in the absence of input signals, no output signals are produced. The output stage should be tested first, followed by its driver, and so forth back to the stage immediately following the oscillator.

When each stage has been given a clean bill of health operated alone, they should be coupled to each other, again starting at the output end of the chain. Only when the entire amplifier chain can be operated at normal operating conditions without output in the absence of input can the transmitter be determined to be oscillation-free.

Output may be detected by means of an rf voltmeter connected to the antenna terminal, or by observing grid current in each stage (any grid current under these conditions usually indicates oscillation is occurring).

It may prove necessary to operate at reduced input voltages, and to supply bias voltage to keep power dissipation within limits. This is particularly true of grid-leak-biased stages; without input signal, they have no operating bias.

A transmitter undergoing such testing should never be connected to an antenna; a well-shielded dummy load is necessary.

54. How can unwanted VHF resonances in a transmitter amplifier be moved from TV channel frequencies?

A. VHF resonances within an HF transmitter are due to stray capacitance of circuit elements resonating with the self-inductance of connecting leads, both internal and external. The resonances can be shifted in frequency by changing either the capacitance of the inductance, or both. Capacitance can be increased by moving leads closer to the ground plane (chassis, in most cases), or decreased by moving leads farther from the ground plane. Inductance can be changed by changing the length of leads. Substitution of different types of components which are electrically equivalent at the normal operating frequency is a frequency cure; disc ceramic capacitors, for instance, usually have much less inductance than do equal-valued micas, and so move the parasitic resonances much higher in the spectrum.

Before attempting any of these cures, however, the specific part or parts contributing to the unwanted resonance must be identified, by careful probing with a grid-dip oscillator. When it is located, its nature usually gives good hints as to the means of moving the resonant frequency.

55. A 70 ohm transmission line is connected to a 35 ohm antenna. Calculate the standing wave ratio (SWR), the reflection coefficient, and the percent reflected power. If 10 amperes are flowing in the antenna terminals, what is the current in a transmission line node? How is the SWR related to the forward and reverse current flow?

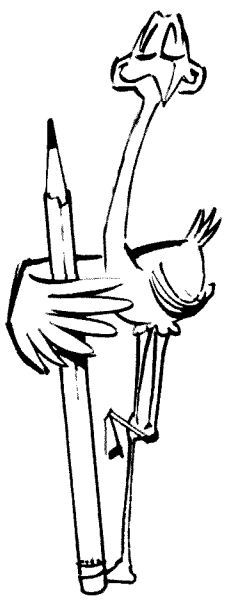
A. When both the line impedance and load impedance are known, the VSWR is found most readily by dividing the lesser into the larger. In this case, it is 70/35, or 2.0.

With VSWR known, the reflection coefficient is calculated by the formula k = (VSWR − 1/(VSWR + 1), which gives us (2−1)(2+1) or 1/3.

Reflected power equals the square of the reflection coefficient, which would be 1/3 times 1/3 or 1/9, and this fraction, expressed as a percentage, is 11.111% (you can carry the string of "1's" out as far as you like).

Assuming that line losses are negligible

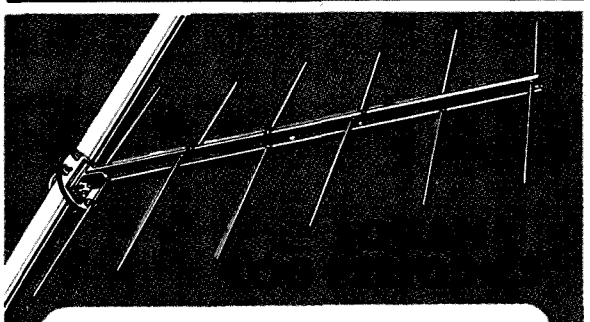
(an assumption which is frequently false, in practice), the current at each node along the line will be equal to VSWR divided by current in the load (where the load impedance is higher than the line impedance, it would be reversed, to be VSWR *times* load current), so in this problem it would be 5 amperes.



Finally, VSWR is defined as the ratio of peak voltage to minimum voltage, or peak current to minimum current. This ratio is related to the forward and reverse current flow by the reflection coefficient. Most present "SWR Meters" actually measure forward and reverse voltage, with the conversion to VSWR accomplished by a meter face which is calibrated by means of the reflection coefficient formula; this formula is algebraically manipulated to yield VSWR $= (1+K)/(1-K)$.

56. What is a grid-bias modulated amplifier? Should the source of fixed bias have a high or low internal resistance? Explain.

A. A grid-bias modulated amplifier is one in which the mixing or modulating action occurs in the grid circuit, rather than in the plate or screen circuits. Modulation is accomplished by superimposing the audio modulating voltage on the fixed bias of the amplifier stage, thus causing the instantaneous grid voltage to vary in step with the modulating signal. Grid-bias modulation is not limited to audio frequencies; it is the preferred method for video modulation of TV transmitters, because the modulation can be accomplished at a relatively low impedance level which permits large bandwidth. The bias source should have low internal resistance, because the grid current varies in a non-linear manner over the modulation cycle, and the flow of grid current through the bias source's internal resistance adds a distorting component to the modulating signal. By keeping the bias source impedance low, this distortion is minimized but not eliminated.



57. Of what importance is the signal-plus-noise ratio of a receiver? At what radio frequencies is this ratio most important?

A. The signal-plus-noise/noise ratio, usually called signal-to-noise ratio and abbreviated S/N ratio, sets an absolute floor to a receiver's sensitivity. Any signal which is

jfj

appreciably weaker than the noise level is buried in the noise, and no amount of amplification can retrieve it because the noise is amplified as much as is the signal. The S/N ratio of a receiver becomes of extreme importance only at those frequencies where external noise is lower than the receiver's internal noise. This occurs near the upper limit of the HF range, somewhere between 15 and 50 MHz (depending upon the location of the receiver with respect to such external noise sources as automobiles, neon signs, and power lines). S/N ratio is always important at VHF and above, but is frequently expressed in terms of "noise figure" or "effective temperatuie." "Low-noise" amplifier circuits are intended to improve the S/N ratio of receivers in which they are used.

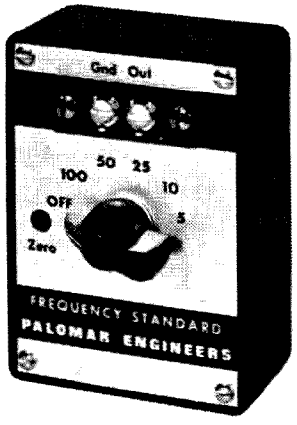
58. What are Aurora-reflected VHF signals? If such a signal is heard, what does it sound like?

A. Aurora-reflected signals are VHF signals which travel from transmitter to receiver by way of reflection from the ionized curtains of the aurora borealis ("Northern lights"). This propagation technique is used at frequencies of 50, 144, and sometimes 220 MHz for extended-range operation. Because the aurora curtains are always in rather rapid motion, the signals are distorted by doppler shifts of frequency; the distortion is usually so severe that voice modulation cannot be copied, and CW becomes the only usable modulation technique.

The tone of an aurora signal has been likened to the whine of a variable-speed power saw burning through a tough pine knot. It is a distinctly uncomfortable signal to copy, but aurora addicts burn the midnight oil in search of VHF DX by this means.

59. What is meant by percentage of modulation? What determines if a carrier wave is under- or over-modulated?

A. Percentage of modulation is a measure of the relative strength of sidebands and carrier wave, applicable only to AM signals in which the carrier is not suppressed, and the measurement is made by comparing the peak envelope voltage to the minimum envelope voltage over a single cycle of the modulating signal. A 100% modulated signal has no amplitude variations and so is effectively unmodulated.



The factor determining under or over modulation of the carrier is the strength of the modulating signal in relation to that of the carrier. Another way of putting it is to say that it is determined by the relative amplitude of sidebands and carrier. "Selective fading" distortion can cause temporary overmodulation of a normal AM signal by attenuating the carrier without reducing sideband level, or undermodulation, by attenuating the sidebands and leaving the carrier strength untouched. For full modulation, the sidebands must be of such amplitude and phase relative to the carrier to produce an evelope in which the instantaneous voltage never falls below zero, and never rises above twice the unmodulated-carrier level.

60. How does a cathode-ray tube operate? What magnitude of voltage is normally used to bias the plates of a cathode-ray tube? What purpose does this magnitude of bias voltage serve?

A. A cathode-ray tube (CRT) consists of an electron gun, which includes a source of electrons in the form of a heated cathode together with electrodes which shape the electron emissions into a tight beam; deflection plates or coils which deflect the beam in both the horizontal and vertical directions; and a phosphorescent screen which glows with visible light wherever the electron beam strikes it. The focused beam is swept over the face of the screen by one set of deflection plates in a known pattern, and signals to be measured are applied to the other set of deflection plates. The resulting visible display on the screen provides the desired information about the signals under test.

The bias voltage on the plates of a CRT is normally several kilovolts more positive than is the cathode voltage. In addition, the deflection plates are biased from 10 to 100 volts with respect to the beam itself. The deflection plate bias is used to position the beam where desired on the screen, by attracting or repelling the electrons in the beam. The high voltage across the beam is necessary to provide sufficient energy in the beam in order to achieve satisfactory bright-

ness of the trace. Some TV sets use acceleration voltages as high as 50,000 (but at only microamperes of current).

61. What are some causes of the excessive production of harmonics in rf amplifiers? How can these causes be remedied?

A. Excessive production of harmonics in rf amplifiers usually results from one or more of three basic causes: the amplifier is overbiased, overdriven, or has insufficient selectivity to reject the harmonics which are a necessary part of Class C amplification.

To remedy the causes, modification of the design is often necessary. No more bias should be used on each stage than is necessary to achieve reasonable efficiency, and no more drive should be applied than is necessary to reach saturation during the signal cycle. Selectivity can be increased by increasing the loaded Q of both input and output tank circuits; this is most easily accomplished by reducing the inductance of the tuned circuit, and increasing capacitance to restore resonance. Reducing the inductance removes resistance more rapidly than it does inductance, thus raising circuit Q (especially since the actual load impedance remains constant).

If excessive harmonics persist after all these remedies have been applied, additional tuned circuits can be added between stages, or at the amplifier output terminals, to aid in their rejection.

Excessive harmonics normally are a problem only with Class C amplifiers; linear amplifiers must be free of distortion, which implies almost total lack of harmonics in their output.

62. What effect does a transmission line which is not properly terminated have on the plate tank circuit of a transmitter?

A. The effect of an improperly terminated transmission line on the plate tank circuit of a transmitter depends almost entirely on the length of the transmission line (both its absolute length, and its relative length in fractions of a wavelength).

If the line is extremely long and has moderate to high losses, the increase in line losses due to the high SWR which results from improper termination will effectively swamp out the reflected power, and at the transmitter end the line will appear to be

properly terminated, even if the actual termination is an open or short circuit. In this case, the effect will be nil.

If, however, the line is relatively short, the effects then depend upon the exact type of termination as well as the length of the line. If the line is any exact multiple of 1/2 wavelength long (electrical length as distinguished from physical length), the load seen by the transmitter will be the same as that existing at the load end of the line. If this load is highly reactive, it will detune the plate tank circuit, possibly so far out of its range that the circuit cannot be tuned at all. If it is resistive (including open and short circuits) the effect will be to alter the amount of power which is extracted from the circuit; the transmitter may load easily, or may "refuse to load" if the impedance is too high.

If the line is any exact odd multiple of 1/4 wavelength long, the impedance at the terminating end will be inverted at the transmitter end. The effects are similar to those of 1/2 wave line lengths, but opens are converted to shorts, low impedance to high impedance, capacitance to inductance, and vice versa in all cases.

For any other line lengths, the impedance at the transmitter end is virtually always reactive, causing tuning difficulties. The major exceptions are those in which the reactance introduced by the line length exactly cancels the reactance present in the improper termination, thus presenting a resistive load to the transmitter. Even in this case, loading difficulties may result.

In general, then, improper termination of the transmission line manifests itself at the final tank circuit as difficulties in either tuning or loading or both. However, in any specific instance a line with mildly improper termination and highly serendipitious length (that means extremely lucky) may tune and load more easily than a properly terminated one. This is the reasoning behind "pruning" of transmission lines to simplify loading problems – which in practice is frequently the most practical solution to them.

63. How are reactance tubes used?

A. In these days of voltage-variable semiconductor capacitors, as little as possible. The reactance tube is an ordinary pentode in a special circuit which causes it to vary its output reactance as a function of its grid voltage, and before simpler components became widely available, such circuits were used to produce frequency modulation by varying the tuning of an oscillator tank circuit, or phase modulation by varying the tuning of an amplifier. Modern designers prefer the voltage-variable capacitor, which is used in the same way but takes a much simpler circuit.

64. How do phasing condensers help stabilize crystal filter circuits?

A. Phasing capacitors perform two functions in crystal filter circuits. They stabilize the circuit by balancing out the capacitance of the crystal's electrodes, thus elminating any path for energy to pass around the crystal itself, and they permit tuning of a rejection notch across the filter's passband, by varying the loading upon the crystal and the phasing of the balancing energy slightly.

65. What means may be employed to measure low frequencies? High frequencies? VHF and UHF?

A. Provided a sufficiently well-equipped lab is available, almost any frequencies short of UHF may be measured by counting the individual cycles for a known period of time, using a gated counter. Such devices are, however, expensive. Most amateurs measure frequencies in the audio range by comparison with the known audio frequencies broadcast by WWV, and those in the rf range up to UHF by comparison to calibrated standards which are calibrated against WWV. The calibrated standards can be used to verify calibration of the station receiver, which can then be used to measure frequencies which fall between the harmonics of the standards.

At UHF, "lecher wires" are often used. These consist essentially of an open-circuited parallel-wire transmission line along which a sensing device can be moved. The VSWR of the line is high because of the open-circuit termination. The sensor is moved through two successive peak or null points and the distance between them accurately measured. This is 1/2 wavelength, which can then be converted to frequency.

A 5/8 WAVELENGTH WEATHER BALLOON VERTICAL THAT WORKS!

The antenna described in the June, 1971 issue of *73 did* work, as verified by witnesses and dozens of FB signal reports. To determine *why* it worked, another weather balloon antenna was sent up on July 16. Viewing the antenna from the ground, the answer was in plain sight, for in the gentle breeze, the antenna was on a 20–25 degree slope most of the time. Guying lines were not used on the first antenna, but were suggested as a method of holding the balloon in wind. Hence, the antenna was not a true vertical, but a "sloping longwire" or Hertz. While obviously the transmitter's pi-network was affording a fair match to it, the SWR observed may have been a false reading.

False SWR readings were also noted by an O.T. when using tuners on the transmitter end with extremely long antennas of this type. His article, written twenty-five years ago, will prove to be most interesting reading.[1]

This time, shooting for 5/8 wavelength, which is optimum for the lowest angle radiation from a vertical, I measured off 83 ft of 22 gage enameled wire for operation on 40 meters. A size "E" (22 cu. ft) cylinder of helium, a helium regulator, and an 8 ft diameter weather balloon were acquired.[2]

Helium and regulators are available from your local welding supply house. You *buy* the contents of the helium cylinder; you

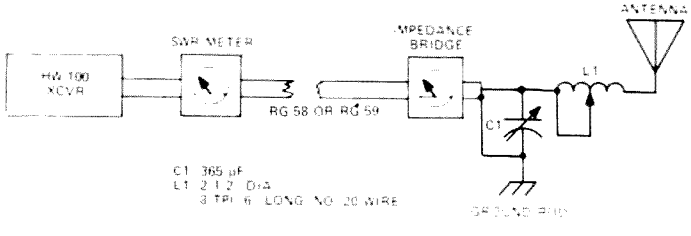

Fig. 1. The equipment setup used to match the 5/8 wavelength vertical. The impedance bridge is not necessary, but saves time by getting the coil tap "in the ball park" quickly. The matching network shown below gives an SWR of 1:1 on 40 meters.

rent the regulator, and put a deposit on it and the cylinder. The deposit is refundable when you return them.

The setup in Fig. 1 was then constructed. The impedance bridge is not necessary but saves time by getting your coil tap "in the ball park" quickly. The particular impedance bridge used here used a grid-dip oscillator for its operation, and thus operating the transmitter was not necessary. If using the impedance bridge in the ARRL handbook, tune up using just enough power to obtain a reading. Set the bridge to 50 ohms or 72 ohms, depending on whether you use RG-58 or RG-59 coax. Using just enough power for a reading on the impedance bridge, run the alligator clip up and down the coil to get a coarse dip on the meter. My coil tap was 4 turns from the antenna side. The 365 pF capacitor is then adjusted for lowest dip with the capacitor approximately half-open.

The impedance meter is then taken out of the circuit and the rig tuned up, again using just enough power to achieve an SWR reading. At this point the SWR read 3:1. This is because the impedance bridge can only read pure resistance accurately and the reactance of the matching network upsets it. A friend stationed in the yard adjusted the capacitor ever so slightly while I motioned through the window, and we had our 1:1 SWR!

We turned up on 40 CW and consecutively worked WB8GBK, WA5UGE, WB9FWJ and W5BYP, receiving 599 reports. Our last QSO was with W3EEK, who gave us a 589. Reason: a 3:1 SWR again.

We ran out back in the dark to find the weather balloon, still fully inflated, sitting on the ground. What brought it down? Dew! The kite string guy wires were soaked with it and quite heavy; for this reason, I recommend lightweight waterproof, floating, fly-fishing line.

With guy wires in place, the balloon vertical will perform satisfactorily on a relatively calm day. However, in stronger winds, the balloon will buffet downward, causing the antenna to become slack and even to touch the ground. For greater reliability, more lift is needed, and hence, more helium. As helium is quite expensive,

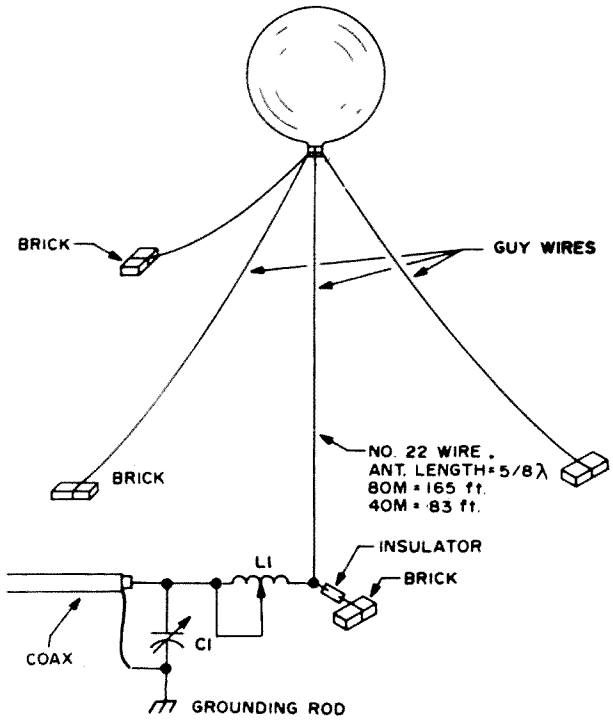

Fig. 2. The 5/8 wavelength weather balloon vertical with base matching network. No ground radials were used, although they could be added to improve performance. C1 – 365 pF receiving type variable; L1 – 2½" dia., 8 T.P.I., 6" long; 40M – 4 turns used.

the alternative then is hydrogen gas. Hydrogen cylinders and regulators are available, but as the cylinder is under great pressure, its use is quite dangerous. A safe alternative is the hydrogen generator kit offered by Fair Radio Sales, which uses lithium hydride in a steel cylinder, and is operated by immersion in water. The firm also sells a balloon inflating tube for use with the cylinder. As their price for the kit is cheaper than a size "E" cylinder of helium (22 cu. ft) and gives more gas volume (approximately 44 cu. ft), it should definitely be explored first, before purchasing helium.[3]

Good luck and good flying! Comments will be appreciated; enclose a stamp.

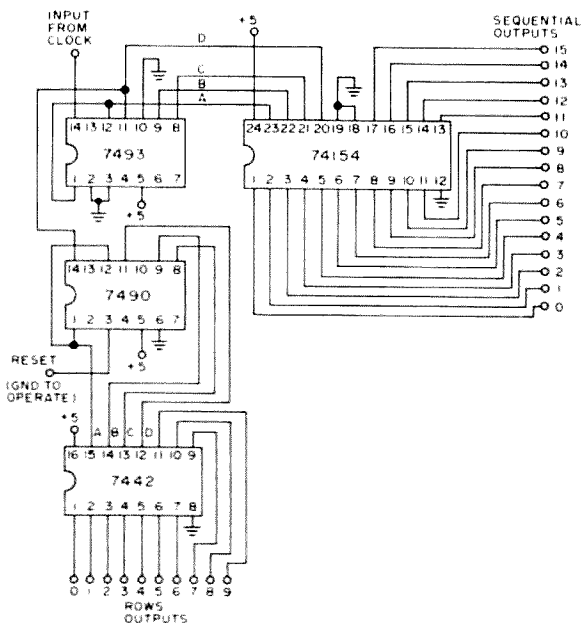
A Simple & Inexpensive ID

Automatic identifiers are the rule now for repeaters and remote base systems, but often the seemingly complicated or expensive electronic ID machines lead many repeater owners to use crude mechanical contrivances. This article describes an ID'er that takes advantage of MSI integrated circuits to reduce cost and wiring effort. This unit was built from design to completion in one day, and cost less than ten dollars in surplus IC's. Without power supply, it is about the size of a transistor radio.

Circuit

Figure 1 shows the basis for the concept behind the simple design of this unit. The entire character generation hardware is simply a counter with the desired outputs decoded to key an oscillator. A counter is a device that takes a series of input pulses to a single input terminal and produces a single output at one of several output terminals in sequence with each input pulse. Figure 1 shows two counters and two decoders. Since the output from the counters is in binary coded



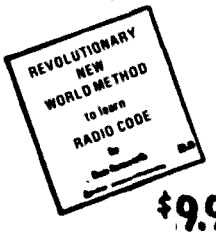


Fig. 1. Sequence generator.

decimal, or binary, a decoder is used to convert the four digit binary number from the counter to a one digit decimal number. The 7493 counter will produce 16 different

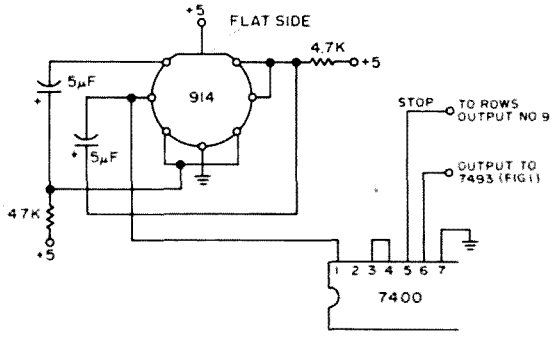
output conditions for a series of input pulses, and the 7490 counter has ten. The drawing of Fig. 1, as with other drawings is an actual wiring diagram rather than a schematic. This will aid in construction and will simplify the description of what it does rather than how it does it. When the simple circuit of the counters and decoders is wired together and activated it can be seen that applying a pulse to the input of the 7493 will cause the output of the 74154 to change by one position. A bounceless pushbutton must be used for this demonstration. The high speed of the counter will show many outputs at one attempt to close or open mechanical contacts. Figure 7 shows a simple circuit that will change state on the first bounce and stay that way until the first bounce in the opposite direction. All but one of the 74154 output terminals will be high. When the pushbutton is pressed and released the low terminal will go high, and the next terminal in the sequence will go low. This is the basic concept of counting. The output of the 7490/7442 decade counting system will change every sixteen pushes of the button since it is connected to the output of the 7493 sixteen counter. This gives ten times sixteen, or 160 different possible states of the sequence generator.



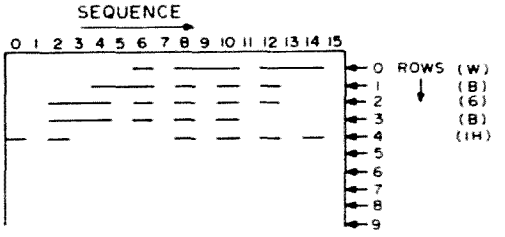


Fig. 2. Clock generator.

Figure 2 is an astable multivibrator that generates a square wave train of pulses to drive the counters. This is also a wiring diagram, but a bottom view. The multivibrator is made from an RTL dual gate μL914. RTL seems to work better in this application than TTL and a few 914's were available for this use. The 7400 is a quad two input gate used to "square up" the output of the 914, and to turn the output of the clock circuit

Table 1
Example for Encoding Character Sequence
WB6BIH

off when the 7442 has reached the next to the last position in its counting sequence. Releasing the reset line in Fig. 1 from ground will reset the 7490 to the first position in its count and start the clock pulses to the 7493. Regrounding the reset lead will allow the 7490 to count every sixteen clock pulses.

By now it is probably possible to anticipate how the ID will work. Table I illustrates how the counters generate the code characters. Each clock pulse represents a unit of time. A dit is one unit, a dah is three units, and the space between them is one unit. A space between letters is five units. The characters are generated horizontally by the output of the 74154, and when one sequence is completed the other counter switches to the next row. This could continue for 160 units, but the decade counter stops at the beginning of the last row, and when it is reset, it starts at the beginning of the first row, so there are only 144 units if the counter is stopped in this manner.

Figure 3 gives an example of how the code characters are selected from the counter output. Since the oscillator is to be keyed only for about half of the time, an eight input gate is about right for each row of sixteen time units. A 7430 is an eight input gate. If any input of the gate is grounded (goes low) the output will go high. This drawing gives the wiring diagram to show how the letters "W" and "B" are generated. In this case each 7430 generates one letter, but for a letter with a lot of dahs in it it may be necessary to use two 7430's for one row. In this case a 7404 inverter section could be used after each 7430, and then connected to the two inputs of a 7400 two input gate section. The outputs also

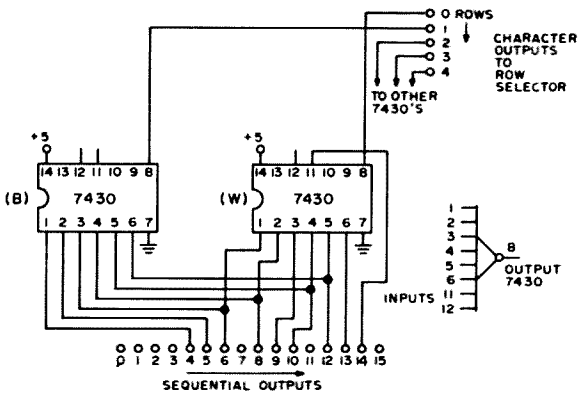

Fig. 3. Character selector wiring example for letters "W, B".

could be connected together simply with two diodes. In wiring up this character selector, a table such as Table I should be written and checked carefully. An error at this point can cause the rewiring of the entire character selector.

Figure 4 shows how the different rows of characters are selected. Both inputs of a 7400 gate must go high for the output to go low. The decade input from the 7442 goes low to select, so a 7404 inverter is used to make them go high. Since each 7430 output goes high, no inverter is needed. These two high going outputs are applied to a 7400 two input gate, one gate for each row. The outputs of the 7400 gates go low, so they are combined at the inputs of another 7430.

It can be seen from this that the number of 7430's, 7404's and 7400's will be determined by the length of message desired. Other information besides call signs may be

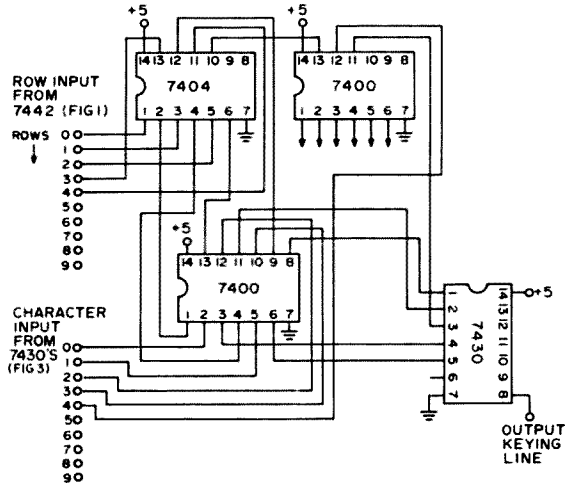

Fig. 4. Row selector.

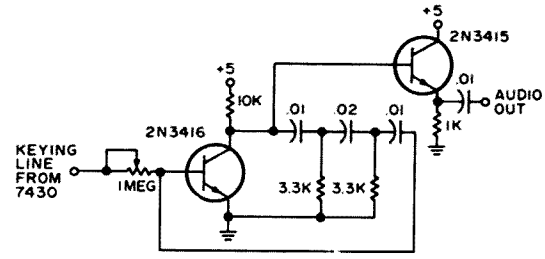

Fig. 5. Tone oscillator.

sent up to 144 units, or a 7493 and 74154 could be used in place of the 7490 and 7442 to increase the length of the message, at higher cost.

Figure 5 is a phase shift oscillator that was used with the ID'er. It is keyed by biasing the transistor on from the high output of the last 7430. The 1 meg pot is used to set bias on the transistor so that the collector voltage is about half of the B+ voltage. There will be beta variations between different transistors so the pot is needed to set bias exactly. It is difficult to get this oscillator to work reliably on five volts at higher audio frequencies because of the low voltage gain, so if higher B+ is available the frequency may be increased by making either the capacitors or resistors in the phase shift network smaller in value. The 2N3415 was added to minimize loading from the output that may prevent oscillation. RF from a nearby transmitter may prevent oscillation, so it may be necessary to shield the oscillator, and bypass and filter the leads to it.

Figure 6 shows a block diagram of the entire unit if there are any questions at this point.

board with holes that match the pins on the IC's. Small wire, solder soldering iron; and long patience are required. The wire ends can be inserted in the holes alongside the IC pin (in the same hole) and soldered. A desoldering tool of some type is helpful since molten solder often sticks in a blob between IC pins and is difficult to remove because of surface tension. The entire thing can be wired in one day, but it may seem like forever.

An LM 335 IC regulator makes an excellent component for a five volt, up to 900 mA power supply. A battery could be used for portable operation. Every HT needs an auto ID.

Results

This article described an automatic identifier that operates with digital precision and solid state reliability. The basic concept is simple to grasp, and the parts are inexpensive. The largest part of the story is told by the drawings, and data sheets obtained from the IC dealers will help the explanation. New or "surplus" IC advertisements at the back of this magazine offer low prices as well as information on the devices, so construction is not beyond someone inexperienced with logic. Since every repeater group must have someone with some electronic experience, there is little excuse for not having an all electronic ID. Perhaps this will eliminate some of the sloppy CW we hear every time 52.525 opens up!

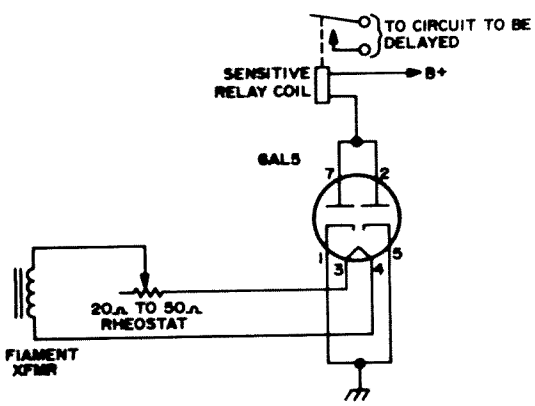
ADJUSTABLE TIME DELAY RELAY CIRCUIT

Any ham who has shopped around for a time delay relay knows they are hard to come by, particularly the adjustable type. Not only are they large but they are also relatively expensive. I have recently seen the vacuum type sealed relays advertised on the surplus market, but have never tried them, even though they were offered at ridiculously low prices, because the delay time was always some figure that didn't tie in with what I had in mind, such as 5 seconds or 5 minutes.

Several years ago I tried the following delay relay circuit, and have used it since. It has given absolutely no trouble, and I still have the original 6AL5 tube in service. It was a used one that had been in a TV set for several years before I junked it out.

As you well know, it takes time for the heaters of indirectly heated cathodes to raise the emitting surface of the cathode to a temperature high enough to start conduction in the tube. Set manufacturers have spent considerable time and money to overcome this nuisance of delay time from the instant the set is turned on to the instant a picture or sound appears. Several "instant on" TV sets have appeared on the market in recent years.

However, it is this "nuisance" that can be put to good use in a time delay circuit. Normally, with rated filament voltage applied, it will take from 10 to 15 seconds for the heater of a vacuum tube to raise the cathode to emitting temperature. We can increase this delay time if we decrease the applied filament voltage. By putting a variable rheostat in one leg of the filament circuit, and a sensitive relay in either the cathode circuit or the plate circuit, we have an adjustable time delay relay. And sensitive relays are available in plentiful supply on the surplus market at give-away prices. My latest flyer from Polypaks lists a SPDT 6500Ω coil, 2 μA relay at 2 for a dollar. This is a fraction of their original cost and a small fraction of the cost of an adjustable time delay relay. A 7-pin miniature socket and a used 6AL5 tube and a 20–50Ω wire wound pot shouldn't be too expensive to obtain, if



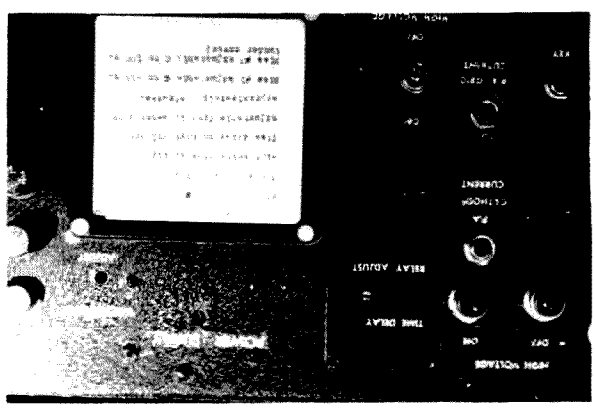


Fig. 1. The basic circuit for the time delay relay.

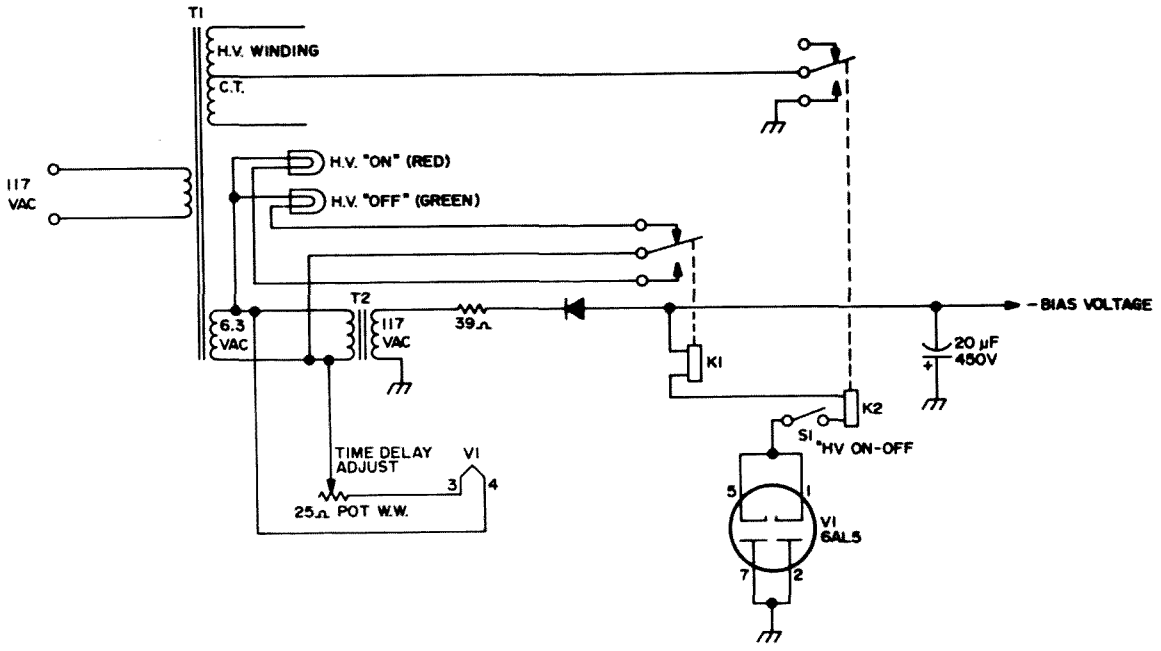
Neat external appearance of relay adjustment screw.



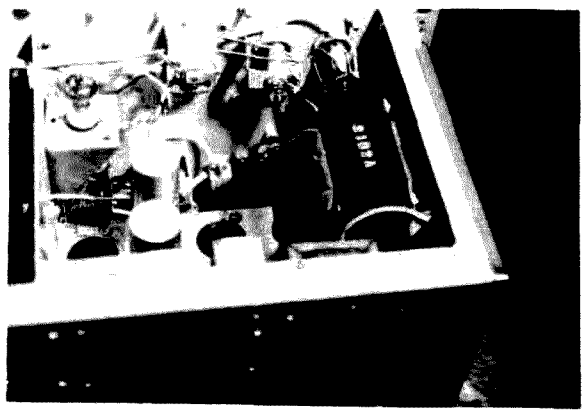


Fig. 2. The time delay relay as used in a power supply.

you don't already have them lying around. The filament source can porbably be found or "borrowed" from existing power supplies in the transmitter or receiver, as can the B plus needed. Figure 1 illustrates the basic circuit.

Figure 2 illustrates how I used this idea in one power supply that I built. T2 is a 6.3V filament transformer, back-connected to a 6.3V winding of transformer T1. This circuit supplies negative bias voltage for the buffer and final stages, through a resistor network and regulator tubes (not shown). I used two sensitive relays, although one relay could have been used if it were the DPDT type. In this case, relay 1 serves no really useful purpose except to "pretty-up" the front panel by turning red and green panel lights on and off. SW 1 opens up the relay circuit so the high voltage can be turned off manually after the delay circuit closes. The 25Ω wire wound pot is listed as available at supply houses, and the value isn't critical. Twenty to 50Ω should do the trick as long as it has the capacity to handle 300 μA of current.

The delay circuit takes up very little space.

One word of caution. Don't check your stop watch by the delay time. With no resistance in the filament circuit, the delay time will vary from 10 to 15 secons; there seems to be that much variation in individual 6AL5s. As the resistance of the pot is increased, the delay time will be increased. Two minutes seems to be about the practical limit. Beyond that, the operation is very erratic, and sometimes the relays will take several minutes to close. I have mine set for about 30 seconds and clocked it several times, and it stays fairly steady at 30 to 35 seconds delay time.

As the photographs show, this installation takes up very little space in the power supply. I originally had 866 Jr's in this power supply, but have since replaced them with silicon diodes. I left the delay circuit in because I liked the idea of letting the final and buffer tubes warm up a little before hitting them with full plate voltage. And I liked the red and green lights.

PETITION TO THE FCC

This petition was originally submitted to the FCC on April 26, 1971. It was acknowledged only as "comments," not as a petition, and no further word has been received from the FCC to date.

Objections to FCC Proposal for Rulemaking Docket 19162.

1. Does nothing to stop U.S.A. CW interference to foreign amateur fone signals and resulting ill will.

2. Does practically nothing to improve the very poor occupancy of all amateur bands caused by overcrowding of fone sub-bands and excessive CW bandwidth.

3. Continues the inequities in privileges all in favor of CW vs SSB fone including; power and communication ranges, suballocation bandwidths, use of international frequencies, susceptibility to mutual interference, and discrimination under the FCC "Incentive Licensing."

4. Continues the coercion of an ex post facto regulation, "Incentive Licensing," under which General Class fone stations lost 50% of their already inadequate and crowded fone frequencies, with Advanced Class fone stations also losing frequencies. Docket 19162 would return only a token part of the revoked fone frequencies and does nothing to alleviate the overcrowding of U.S.A. fone sub-bands, where only the highest power fone stations are frequently able to operate, and as a result many amateurs have quit amateur radio in disgust.

5. In the 80 meter band, Extra and Advanced Class stations could use fone in only a small already crowded portion of the international communication frequencies. Most of Region 3, Russia and many other foreign countries still could not be contacted directly.

6. A piecemeal extension of only Extra and Advanced fone stations into a small portion of the international frequencies without clearing out the widespread and unnecessary CW interference from U.S.A. stations will only add more confusion and probably more ill will.

Points of Agreement with FCC Proposal Docket 19162

1. The direction is correct in allowing U.S.A. fone stations to operate in frequencies established for international amateur communications.

2. Reduction of the exclusive Extra Class CW segments from 25 KC to 10 KC is justified because of poor occupancy. But all U.S.A. CW including the Extra segment should be moved out of the inadequate and extremely crowded international frequencies 7.0 to 7.1 MC as explained later.

General Considerations for Amateur Band Suballocations

1. U.S.A. CW amateurs can operate throughout all bands, regardless of interference produced on amateur fone signals, foreign or domestic. U.S.A. fone stations are allowed only small fractions of the amateur bands under present FCC rules, and the fone sub-bands are greatly overcrowded while large portions of the U.S.A. amateur bands frequently have negligible occupancy.

2. In the face of already crowded fone segments and the accelerated growth of SSB fone communications throughout the amateur bands, FCC's "Incentive Licensing" regulation arbitrarily cut the crowded fone bands in half for the largest group of General Class stations. The Advanced Class stations also lost fone frequencies. Many amateurs gave up in disgust, others switched to CW with its undiminished privileges, and many were coerced into becoming technical and Morse code experts and passing the Extra Class exam, *in order to regain the fone frequencies which had been taken away under "Incentive Licensing."* But nothing of consequence had been taken away from General Class CW operators who can still contact all foreign countries directly in the international frequencies of all bands, even though they are less qualified technically and in code speed than Extra Class fone operators who cannot contact fone stations except with split frequencies on the 40 and 80 meter bands – and with U.S.A. CW interference on the weak foreign signals.

3. It is apparent that "Incentive Licensing" tends to: perpetuate the semi-obsolete CW mode and discriminate against fone, prevent almost all foreign fone contacts by General Class fone stations, overcrowds the fone bands so as to discourage fone operation except for highest power stations. Why were no sanctions placed on General Class CW operators if the purpose was to upgrade licenses? Why are FCC monitoring stations ignoring all CW interference to foreign and domestic fone signals? It seems obvious that the FCC Amateur Division has been and probably still is dominated by CW advocates.

4. Split frequency fone operation is required on the 40 and 80 meter bands because U.S.A. fone stations are not allowed by the FCC to transmit in the frequency ranges agreed upon for international communications. And foreign fone stations cannot operate in most cases in the U.S.A. fone frequencies because in the rest of the world the U.S.A. fone frequencies are allocated to high power broadcasting, commercial and jamming stations. Many of the high power signals are more audible to foreign amateurs than in the U.S.A. Thus it is almost impossible for a U.S.A. fone station to pick a frequency where it can be heard in a foreign country, and it is equally difficult for a foreign station to find a U.S.A. station in the strong commercial and broadcast interference of the present U.S.A. fone bands. Split frequency fone contacts are wasteful of frequency space and are especially bothered by unavoidable as well as deliberate interference at both ends.

5. SSB fone requires about 2000 cycles bandwidth and at least 100 times the 20 cycle bandwidth needed for typical CW signals. With proper receiver filters and assuming full power for each mode, the signal/noise is at least 20 dB better in CW vs SSB fone, equivalent to 100 times in

power. The International Regulations (694-2) state, "All stations shall radiate only as much power as is necessary to ensure a satisfactory service." The use of unnecessary power is also a factor in TVI. Since 1 KW is the maximum power allowed SSB fone it would seem proper to limit CW to the same communication range as SSB fone. Therefore, the maximum power for CW should be reduced to 10 watts. Furthermore, since there are fewer CW than fone signals on all amateur bands the CW sub-band should not exceed 1% of the total in each amateur band.

6. SSB fone signals are much more susceptible to CW interference in the 2000 cycle bandwidth than are CW signals requiring only 20 cycles bandwidth. With proper CW filters a CW operator is able to reject almost all interference such as other CW signals which would completely blot out an SSB fone signal. Rejection tuning controls have been tried in SSB fone receivers but experience shows that rejection of even a single strong CW signal is not possible without partial or complete loss of intelligibility of a weak fone signal. As many as 100 distinct CW signals could be selected within the 2000 cycle passband needed for SSB fone. It is imperative that SSB fone have the "right-of-way" over CW and the only practical way is to segregate U.S.A. CW stations into an equitable sub-band.

7. Because of crowded fone bands, SSB fone equipment has undergone intensive development, to optimize SSB communications and to reduce interference between fone signals. Many new SSB receivers, transmitters and especially transceivers are produced each year in ever increasing quantities and in several countries. On the other hand there has been little if any progress toward achieving the potentialities of CW communication, probably because of excessive power and bandwidth allowed CW, and the ability to reject most interference with simple audio filters under these favorable conditions. A receiver having optimum design for CW reception is not known to have been described in the literature, or to be available for sale to amateurs.

To stimulate the development and design of improved CW receivers and filters and to allow time for CW operators to update their equipment, compromise bandwidths and power are proposed for amateur CW stations on a temporary basis. Instead of 1% for a CW sub-band, a range of 8 to 15% is suggested in various bands for the reasons described, with a power limit of 100 watts. The CW power limit might be reconsidered in a future international meeting.

8. U.S.A. CW interference, usually between U.S.A. CW stations, is particularly bad in the 40 and 80 meter bands and effects fone contacts between foreign fone stations as well as between foreign and U.S.A. fone stations in crossband operation. Considering the small number of CW signals and the large unused frequencies in these bands there is absolutely no valid reason for CW stations to interfere with foreign fone signals. Again, the answer to CW interference is segregation into an equitable sub-band for all U.S.A. CW stations. Examples of CW interference on the 40 and 80 meter bands follow:

3.55–3.7 MC 9–12 GMT:
Japan, Australia, etc. fone.
3.7–3.8 MC 22–14 GMT:
Europe, Africa, Region 2 fone.
7.0–7.1 MC 22–14 GMT:
Regions 1, 3, most of 2 fone.
7.15–7.2 MC 22–14 GMT:
Region 2 fone.

W1AW (ARRL) teletype broadcasts regularly kill all foreign fone contacts on or near 7.095 MC. Daily CW nets on 3790 (W5's) regularly interfere with Canadian phone patch nets on the same frequency. A number of U.S.A. CW stations normally operate on top of strong Canadian fone stations in the 3.75 to 3.80 range and sometimes above 3.8 in the U.S.A. Extra Class fone sub-band. U.S.A. Novice CW stations also operate in the "Canadian" fone band in the range 3.725 to 3.750. As a direct result of the U.S.A. CW interference, Canadian fone stations have managed, however deliberately, to prevent U.S.A. fone stations above 3.8 MC from contacting weak foreign fone stations who attempt to operate just below 3.8 in the required split frequencies. The situation has persisted for several years with a small but well known group of VE3 fone stations, many with very strong signals which preclude reception of any weak foreign signals, even if no U.S.A. CW signals are present.

It makes no sense to add to the present mess of signals below 3.8 MC and below 7.1 MC by allowing Extra and Advanced U.S.A. fone stations to operate in the proposed (Docket 19162) small segments of the international frequencies without clearing out the compeltely unnecessary signals, the root cause for widespread ill will. A far better solution to the problem of international fone contacts for U.S.A. fone stations results from segregation of U.S.A. fone and CW signals into equitable sub-bands. General Class fone stations must be given the same rights to contact foreign fone stations in the international communication frequencies which General Class CW stations have enjoyed with foreign CW stations.

9 Amateur bands belong to all amateurs in all countries and efficient use of these bands requires maximum occupancy and maximum communications between all radio amateurs, eliminating unnecessary, irresponsible and deliberate sources of interference wherever possible, and establishing equitable sub-bands for non-compatible modes of transmission. The FCC and the U.S.A. must provide leadership in establishing sensible sub-allocations for U.S.A. radio amteurs.

Regarding the statements of certain Canadian groups, it is ridiculous that a VE3 fone station in Niagara Falls Ontario should be able to contact European fone stations directly in the international frequencies below 3.8 MC while a W2 in Niagara Falls, New York, cannot – even with an Extra Class ticket. There are just not enough frequencies available in the amateur bands so that the U.S.A. with over half of the world's amateurs should limit its fone bands to only Stateside contacts, while providing for exclusive use of all of the international frequencies by neighboring countries. This is clearly a violation of civil rights for the U.S.A. fone amateurs.

There is also no question of "domination" of the amateur bands by U.S.A. fone stations because propagation to the rest of the world at best occurs for only a few hours each day, if at all, for only a few days each month, and on most amateur bands for only a few years in each 11 year sun spot cycle. The unfortunate crowding of the U.S.A. fone bands with only strong signals able to compete might suggest "domination" of the entire band if the fone bands are expanded. Similar crowding of VE fone stations into a 10 KC fone band would justify a similar argument.

There are today Canadian, South American and other amateur stations having signals as strong as, if not stronger than most U.S.A. stations. Maximum power, so called, is no longer a perogative of U.S.A. amateurs, and enforcement of a power limit for transmitters is probably as lax in foreign countries as it is in the U.S.A.

There is no provision in the international agreements for exclusive use of amateur frequencies by one country at the expense of another. There are no national boundaries to divide the amateurs of one country from those in another country, except as determined by each country in its rules and regulations The answer to any possible crowding of Canadian fone stations should come from

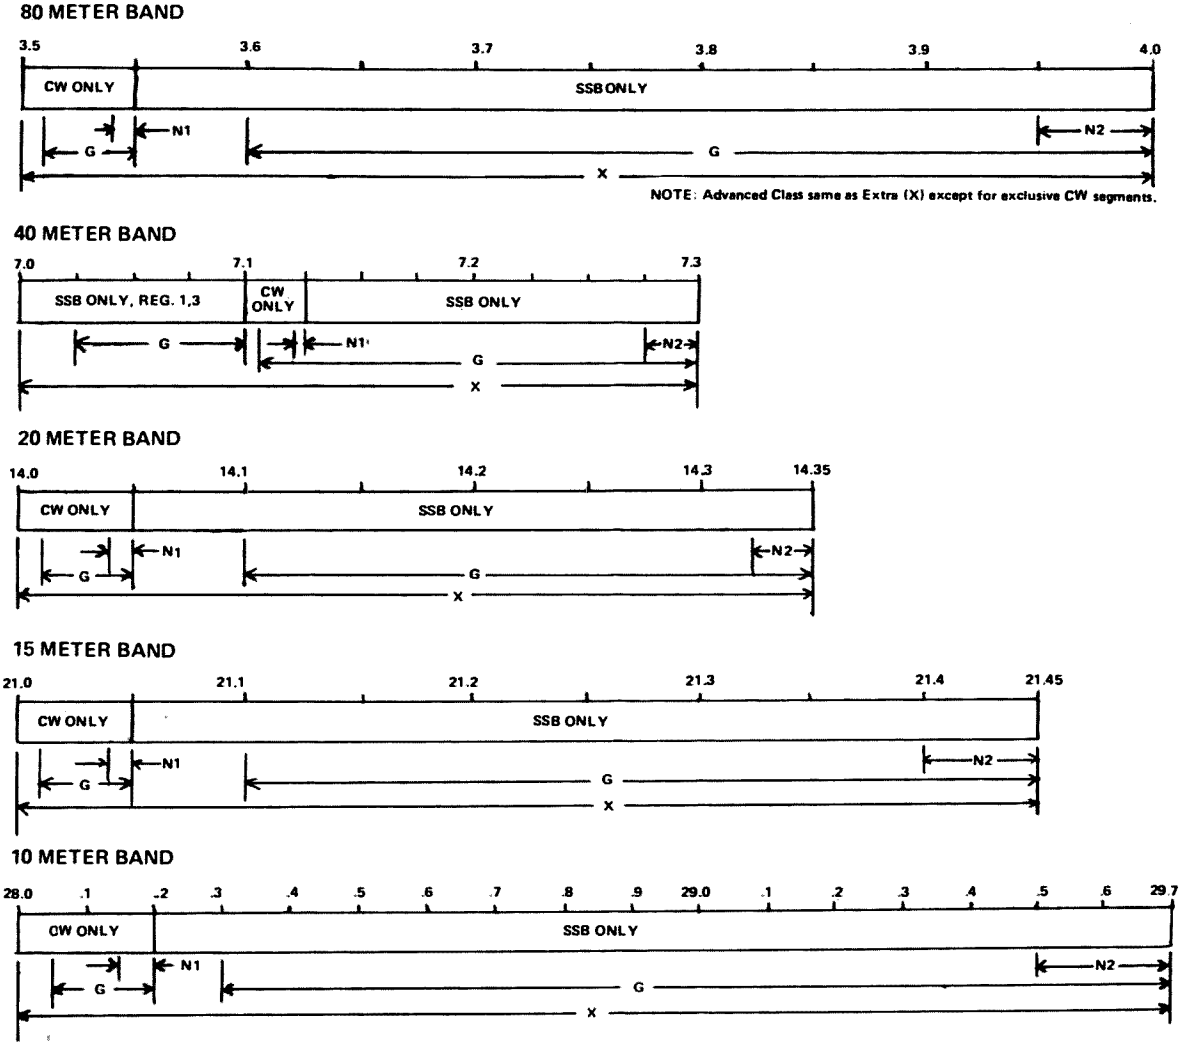
Ottawa and not from the FCC. And the answer to crowding of U.S.A. fone stations is full usage of all amateur bands based on an equitable segregation of CW stations.

10. The proposed Suballocation Chart is simplified to CW and SSB fone modes of transmission. SSB fone includes any single sideband transmission. SSB fone includes any single sideband transmission, as of a slow scan TV picture. AM, (amplitude modulation), FM (frequency modulation) DSB (double sideband) and slow scan TV as an AM signal are all omitted because all tend to cause unnecessary interference and are wasteful of frequency space. A time limit of perhaps 2 years should be placed on these transmission modes with interim operation limited to the proposed Novice fone band.

There is little justification for exclusive Extra Class fone bands, or for becoming a Morse code expert in order to be able to contact certain foreign stations using fone, as on the 80 meter band. Since the Advanced and Extra Class exams are essentially equivalent except for the code test, the Extra and Advanced fone subbands are identical.

Similarly, Conditional licenses are assumed to be the same as General Class, although the reason for so many Conditional Licenses is not understood.

11. Lack of occupancy by the U.S.A. of the international amateur frequencies has invited takeover of these frequencies by unauthorized transmitters and eventual loss of these frequencies. Those in the FCC Amateur Division who oppose legitimate and obviously needed expansion of the U.S.A. fone bands should ponder these facts.



Specific Proposals for Amateur Band Suballocations

See chart

U.S.A. CW stations are segregated into an adequate "CW only" sub-band at the low end of the international frequency range 3.5 to 3.7 MC. An exclusive 10 KC segment for Extra Class CW, identical with the FCC proposal in Docket 19162, is included plus a 10 KC non-exclusive CW segment for Novices. The 50 KC CW sub-band has ten times the indicated bandwidth for an equitable division of the 80 meter band with U.S.A. SSB fone, as a temporary expedient and for the reasons described previously.

SSB fone has the remaining bandwidth with an exclusive 50 KC seg-

PROPOSED SUBALLOCATIONS FOR USA RADIO AMATEURS

ment for Extra and Advanced Class fone, and a non-exclusive 50 KC segment for Novice (N_2) licenses which are described later.

The proposed CW and SSB fone sub-band provide:

1. Elimination of U.S.A. CW interference on foreign and U.S.A. SSB fone signals.
2. Elimination of U.S.A. SSB fone interference on CW signals in the CW sub-band.
3. Maximum occupancy of the entire U.S.A. band.
4. All classes of U.S.A. SSB fone stations can contact all foreign fone stations directly.
5. General Class fone has four times the present bandwidth, with equal rights to contact foreign fone stations.
6. More U.S.A. fone stations should be able to operate with modest power, and antenna investment.
7. Attraction for many fone stations forced to stop operating because of "Incentive Licensing."
8. Reasonable incentive for upgrading licenses.
9. Provision Novice (N_2) SSB fone experience.
10. Fosters worldwide fone contacts and development of better equipment and antennas for 80 meters.
11. Stimulates improvement of CW equipment.
12. Anticipates optimum communications and maximum usage of this band during several years of minimum sun-spot activity.

Amateur Licensing Proposals

The exams for amateur radio licenses include technical and regulation questions which can usually be learned after reasonable study, plus the ability to transmit and receive Morse Code. Learning the code is difficult for most and especially for those who are only interested in fone communication.

The international regulations require that amateurs shall be able to send and receive Morse code but they do not require amateurs to become experts in Morse code before being able to make foreign contacts by voice. Instead of primary emphasis on Morse code it is suggested that operating proficiency and experience should be required at each step above the initial Novice license. This suggestion is based on the gradual obsolescence of the CW mode, the worldwide trend toward SSB fone, the vagueness of the old international regulations on code speed, the lack of code tests in some countries, and the growth of "amateur" activity in the citizen's band.

It is suggested that the present Novice Class be known as Novice (N_1), but with greater freedom in operating on all bands, although in a narrower frequency segment. Furthermore, tunable oscillators are suggested so as to permit contacts on the same frequency and to prevent obsolescence of special Novice transmitters. Still another reason is to permit a logical progression to Novice (N_2) SSB fone operation.

The Novice (N_2) exam might require that 25 QSL confirmations must be verified before the exam is taken, and verification might be made by a qualified amateur who would also conduct the exam in a manner of a Novice (N_1) exam. After passing the N_2 exam a Novice (N_2) license (or endorsement of the N_1 license) would permit operation in both CW and SSB fone Novice segments. However, before the General Class exam could be taken the Novice operator would have to receive QSL confirmations for at least 25 or 50 2 way SSB fone contacts. In this way all Novice operators would have to demonstrate operating proficiency in both CW and SSB fone before a higher grade license could be obtained.

Similar requirements for confirmations might be added for higher class licenses, for instance perhaps 100 countries for an Advanced, and 250 before an Extra Class exam could be taken.

It should be mandatory for U.S.A. amateurs to answer all legitimate requests for QSL cards, or have their licenses suspended, or even cancelled, when many complaints are received. QSL replies are as important as foreign contacts in fostering good will.

Exchange of QSL cards may be rather expensive, or quite slow when QSL Bureaus are used, for confirmation of foreign contacts. The U.S.A. exports many things for free, why not QSL cards?

40 Meter Band (7.0–7.3 MC)

All of the fone and CW amateur stations in Regions 1 and 3 have only a very restricted frequency range of 7.0 to 7.1 MC, and some countries in these regions allow only a small portion of this range. Additionally, most South American amateurs in Region 2, which can operate throughout the 7.0 to 7.3 MC range, prefer to operate below 7.1 so they can contact foreign stations directly, and to avoid the extremely strong broadcast, jamming, and commercial interference above 7.1 MC and extending to 7.3 MC. But U.S.A. CW stations usually in contact with other U.S.A. CW stations cause the greatest interference in the overcrowded international band 7.0 to 7.1 MC, and particularly with foreign fone signals. The CW interference causes widespread ill will and is inexcusable, and unnecessary, because CW operation including Novice CW normally operates on split frequency, whereas SSB fone normaliy uses transceivers which must operate on the same frequency.

It is proposed to provide a "CW only" sub-band at 7.10 to 7.125 MC with 5 KC segments for exclusive Extra Class and for non-exclusive Novice (N_1) CW. The 25 KC CW sub-band is consistent with the limited total bandwidth, and with the restrictions placed on SSB fone operation below 7.1 MC. It is also easier for CW to cope with broadcast and other interference because of its narrow bandwidth requirement.

To minimize U.S.A. fone interference in the crowded 7.0 to 7.1 MC range, it is also proposed to limit direct U.S.A. fone contacts to Region 1 and 3 fone stations, and within segments allowed each license class.

A 25 KC Novice (N_2) fone band is shown at the top end but otherwise there is no split-up of the fone range above 7.125 MC because of the heavy interferences mentioned above, and therefore the limited usefulness of the fone range above 7.125 MC. General Class fone would have five times the present fone bandwidth including Regions 1 and 3 under this proposal.

10, 15, and 20 Meter Bands

These three bands already have some capability for direct fone contacts with foreign countries, although the General Class fone bands are usually very crowded and fone operation is limited to a fraction of the total available bandwidth. The occupancy during periods of good propogation is relatively poor, particularly on the 10 meter band. It is suggested that this band be reduced to the range 28.0 to 28.5 with the same sub-bands as proposed for the 80 meter band.

The 15 meter band is nearly as wide as the 80 meter band and has about the same sub-bands for all modes and license classes as proposed for the 80 meter band.

The 20 meter band is particularly useful for long distance contacts throughout most of the sun spot cycle and also popular for contacts between U.S.A. stations. The 50 KC CW sub-band is relatively wider than on other bands while the proposed Novice fone band is only 25 KC wide. Both variations recognize the relatively greater present occupancy of the 20 meter band. Nevertheless, General Class fone would have 3-1/3 times the present bandwidth and the ability to contact all foreign fone stations directly.

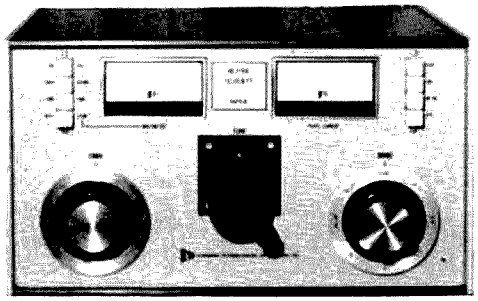
POWER LEAD FILTERS FOR 432

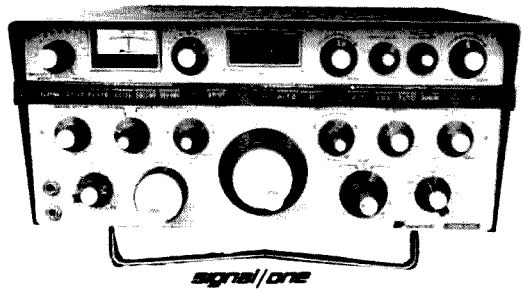
There is a particularly nasty form of trouble which can afflict solid state transmitters, and multi-rf stage receivers too, much more than the old fashioned tube jobs, and considerable attention must be paid in order to avoid it. This is interstage coupling through the low-impedance power lead connections and wires which ordinarily with tubes would not allow sufficient rf voltage to be sent from stage to stage to cause much trouble.



Even with tubes, precautions against this type of trouble had to be taken at times, especially as one went higher and higher in frequency up into UHF. One of the bad features about it is that it can happen easily enough between a first stage and a last stage, transforming one millivolt into one volt and causing violent reaction.

Very complicated power lead filters have been devised for this deal, as for example 8 and 16 section filters for an 8 tube radar i-f strip.

Ceramic feedthrough bypass capacitors were designed for use where power leads went through partitions, which cut down the nuisance rf voltage to a certain extent, enough for the tube type sources, exciters, and finals, if sufficient care and shielding was used in the overall design. Some of these ceramic feedthroughs work at 432 and some do not, as you will see.



Now we are faced with devices (transistors) which exaggerate this kind of trouble due to very low rf impedances. Some transistor collector circuits operate with impedances of less than 10Ω, and for high power it may go under 1Ω. This means that a bypass that was good at 432 MHz with tubes, may let through rf voltage at low impedance, driven by those high current solid state devices to couple back from the

final right past a "bypass" capacitor and into the exciter and knock it right out, subject to the phase involved. Or worse, throw the stages into self oscillation, because the input of these devices is also low and so operates on very small voltages of just the kind we're talking about. This is further aggravated if low cost devices are used in the first stages because then the low level operation is more subject to feedback.

Low cost in tubes was nothing. A 6CL6 for $1 had a Gm of over 10,000 and could deliver a watt or more as a 54 MHz crystal controlled oscillator. The same type would then double to 108 with several watts, and two $4.50 surplus 2C39's with Gm's of thirty to forty thousand brought you up to 432 with 5W.

Solid state devices are not quite up to that point as yet, unless money is no object and you order several dozen of the very latest at $200. Even with that kind of money, specs sometimes read like "two watts at 2GC" and then if you read the fine print or turn the page you'll find "gain of 4 dB."

Fortunately it's not quite that bad on 432 MHz, but say you've got a gain of 10 or 12 in each of two rf stages, the last one putting out one or two hundred milliwatts and you couple back just one percent along the battery leads to a triple stage with an output of only one or two milliwatts. You see what can happen? And it does, too! Not only that, but if it just happens to be in phase, you get output even when you pull the crystal out, and that is about the worst thing that can happen to any transmitter.

So it will pay to examine this question in detail, because as amateurs we have an obligation as well as the need to develop our skills in the art, and this subject is a basic one for all types of transmission and reception by solid state devices.

With this in mind, I started in on the power lead filter deal with the goal being a small low-cost unit easy to make, with at least 40 dB of attenuation in voltage, if possible. It turned out that it was.

These tests and the final low cost filters are good for receivers also. A contemporary author in a magazine I happened to be

reading recently mentioned, "You'll have an easier time with one rf stage than with two." No argument there at all. Just that these tests and filters should help reduce the effort needed to "tame" two rf receiver stages, as well as multi-stage transmitters.

How to Get "Cold" Connections

Most of our work on UHF calls for hot wires, that is, wires carrying plenty of rf, and losing the least amount possible through insulation losses, radiation, wire resistance, or by any other nuisance method. For power leads we want just the opposite, to carry dc and lose all the rf immediately. Or at least so much that you can neither detect it, nor find any nuisance effects, which amounts to the same thing. An oscillator and rf amplifier will do for the source and a tuned diode detector will do the job of measuring. After all, we're not doing a research job for a capacitor company, we're just interested in learning how to put a solid state transmitter on the air with a good stable signal without touchy feedback, connectors that jump rf-wise, and other transmitting plagues. The same holds for the multi-stage receiver also.

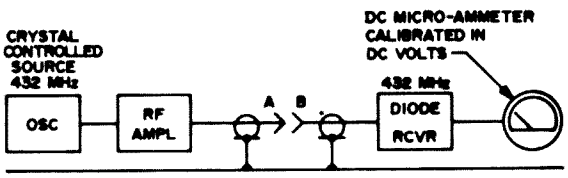

Fig. 1. Test setup, power lead filters.

Figure 1 shows a test setup that can tell us what's what in this matter. After all, if I do it and tell you about it, that gives you more time to build things and get them on the air.

At "A" we have a good 20 mW at 432 MHz coming onto the test plank. At "B" we have another cable going to the tuned diode detector, and with the units shown the meter reads 4V dc when "A" is connected to "B."

The trick is to connect "something" between A and B that will carry heavy current 12V dc with only a small drop or none at all. This may mean a thin wire choke, or a resistor for a low power first stage drawing only 10 or 20 mils and it may mean later on a heavy wire choke for 12V at ¼A for a 3W final.

Tests

Referring to Fig. 1, all results are given in dc volts at the output of the diode detector.

Coaxial cable A to B, 4V; piece of wire on the ground, 3.5; piece of wire with 1000 pF to ground at B, .3; 1000 pF at A, .29; 1000 pF at A and B, .04 (40 mW); 100Ω resistor between A and B, .042; with 1000 pF at A and B, plus 100Ω between A and B, 0V. This could be used with a low current stage like a receiver where even down to 6V is all right for low noise rf, but let's keep going. You certainly couldn't modulate a solid state final through a 100Ω resistor.

Choke coil between A and B, No. 40 wire, ¼ in. diameter, length ½ in., no capacitors, .2; with 1000 pF at A, .01V; with 100 at A and B, ½ mV. Beginning to look good.

Ten turns No. 34 wire, 20 mV, showing that the choke question is subject to variations in filter power, in this version.

Yellow surplus choke, 1/8 in. diameter, ¼ in. long, about 25 turns, 1 mV, good but not quite the ideal yet. Ten turns on the choke and 1000 dipped mica at A and B, 10 mV. Same, with small 3/16th Lafayette ceramics, 3 mV.

Homebrewed flat coax, as in Fig. 2, 10 mV; two 1000 pF at A and B, plus 20 turn choke, 1 mV. At this point I thought about a small module as in Fig. 2. The meter hit the pin. Bringing the two capacitors to *one*

Features:

- RELIABILITY IS NOW standard equipment. Every CX7A "burnt-in" and cycled more than 96 hours.
- QUALITY-PLUS. Every component is instrument grade. American-made, and individually tested.
- ALL MODES 10 thru 160 meters in full 1 MHZ bands with overlaps.
- BROAD-BAND TUNING. Instant band changes without tuning.
- TRUE BREAK-IN CW with T/R switching.
- IF SHIFT – deluxe QRM slicer.
- PRE-IF NOISE-BLANKER that really works.
- RF ENVELOPE CLIPPING – sounds like a Kw.
- TWO VFO'S Transceiver Plus receiver.
- BUILT-IN: Spotter, FSK shift, transmit offset, wattmeter, SWR meter, electronic CW Keyer.

Specifications:

- SENSITIVITY: Better than 10db signal-plus-noise-to-ratio for .25 microvolts at 28 MHZ.
- SELECTIVITY: 2.4 KHZ @–6db, 1.8:1 (6:60db) shape factor. (16 pole crystal lattice Filters)
- optional: CW-300 and 400 HZ. FSK-1200 HZ.
- CARRIER and unwanted sideband suppression. Minimum 60db.
- IMAGE and IF REJECTION: more than 60db.
- POWER LEVEL: 300 to 500 watts p.e.p. continuous duty cycle.
- POWER AMPLIFIER: 8072 final completely broadbanded driver and final. 150 watts continuous dissipation rating.

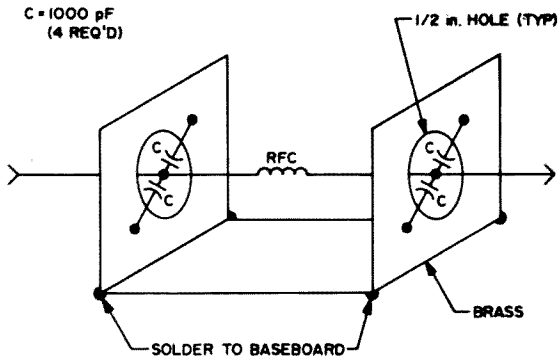

Fig. 4. Brass frame module.

connector, which had some inductance to ground, was absolutely no good.

I then cut out a small brass frame as in Fig. 4. Hurray! The first time to hit a real zero volts. It makes you haul out the ohmmeter and check for a short or an open! Same, but without choke, also zero.

I noticed that every time I checked with another 1000 pF on a little coffee stick from A or B to ground, in effect paralleling the one already there, the meter plunged to near zero. At 432 MHz this is the same thing you may have read about more than once in my writings. More than one capacitor at the same place. It parallels the inductance and drops it.

Now we're getting close to the ideal; in fact, to cut it short, Fig. 5 shows the ideal. No brass plate is needed, and you can use it either on the baseboard or with the choke resistor installed in a hole in a box wall, or what have you.

The two-section filter using 4 capacitors plus a choke in between, really does the job. You imagine the meter moves, maybe. There might be somewhere between 1/10th and 100th of a millivolt of rf leaking through, and some or all of this may be "jumping" through the air.

So now you can make up units in advance, as in Fig. 5, and be sure they'll work at 432 MHz.

30 pF Capacitors

Just for fun, another two-section filter was assembled, as in Fig. 5, but with the low value of 30 pF for each of the four capacitors. Of course at 432 MHz the rf impedance of 30 pF looks almost like a dead

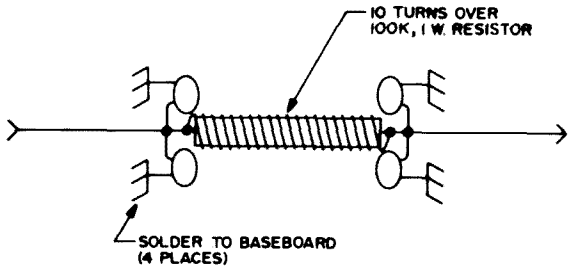

Fig. 5A. Ideal low-cost power lead filter, top view.

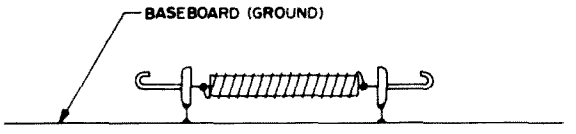

Fig. 5B. Side biew of power lead filter.

short, and it was. I could not tell the difference between the 150 pF filter and the 30 pF one. This makes it easy if you have large quantities of surplus dipped mica capacitors of odd values.

The reduction in rf voltage is something like 50 dB, dropping from 4V down to about one hundred thousandth of a volt. This is plenty for power lead filters. The cost in parts is that of four capacitors at around 10¢ each, and a resistor for a coil form.

"Boughten" Feed-through Capacitors

The first ones tried were disappointing. The type "FT," shown in Fig. 6 allowed 20 mV to leak through.

I did dig up a couple of good ones out of a 1946 surplus UHF Navy unit. I suspect that the price will be quite high on such units, if they can be found. These look like Fig. 7, and perhaps some reader from the sales department of Sprague or Centralab or

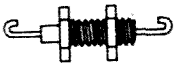

Fig. 6. Type "FT" feedthrough capacitor.

Erie can tell me what they are, and for how much to amateurs interested in good UHF feedthrough bypasses. They do seem to work as well as the final form shown in Fig. 5, so if you can find them, pay the price, and have a wall to put them in, such as in an enclosed rf stage, you can use them.

Subminiature Filters

The test setup of Fig. 1 being in operation, a smaller version was tried, to be ready for the size reduction being looked forward to with all kinds of new and exciting very small components becoming available on the market.

As long as 30 pF capacitors worked well, anything over that would naturally be all right, so with a tenth watt resistor for the choke coil form, away we went.

While this is not as small as can be made today, when you get into chips and hybrids, prices go in an inverse ratio. Little 1/8 in. x 1/8 in. x 1/16 in. square Lafayette ceramics cost around 13¢ so we still can call this one low cost.

The assembly is just the same as in Fig. 5, with the total space occupied being ½ x 5/8 x ¼ in., and, as mentioned, it could be cut down even more if you tried.

It worked just the same as the larger one in Fig. 5. Need I say more?

Checking Out the Filter

Figure 8 shows the results of tests conducted on a crystal-controlled exciter and rf final destined for use in the 432'er solid state assembly. Note the one volt of rf at test point D *without* the filter. At the same point, also without the filter, about a tenth of a volt was found with only the exciter fired up. See Fig. 9. You can see what that kind of rf path will do for feedback from a quarter watt or a one-half watt final.

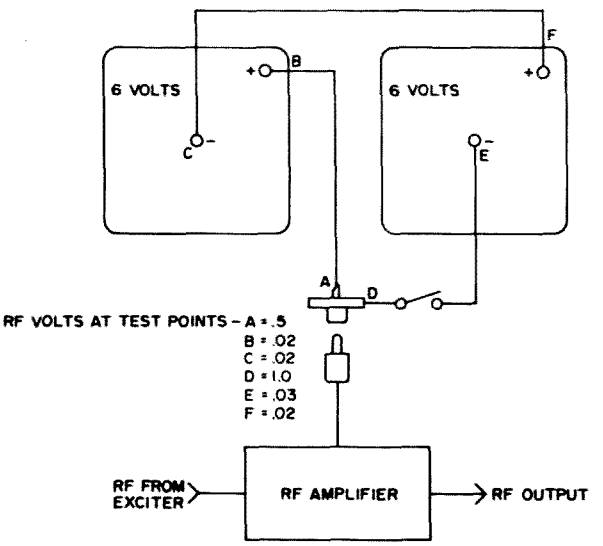

Fig. 8. Test results, rf on batteries and leads.

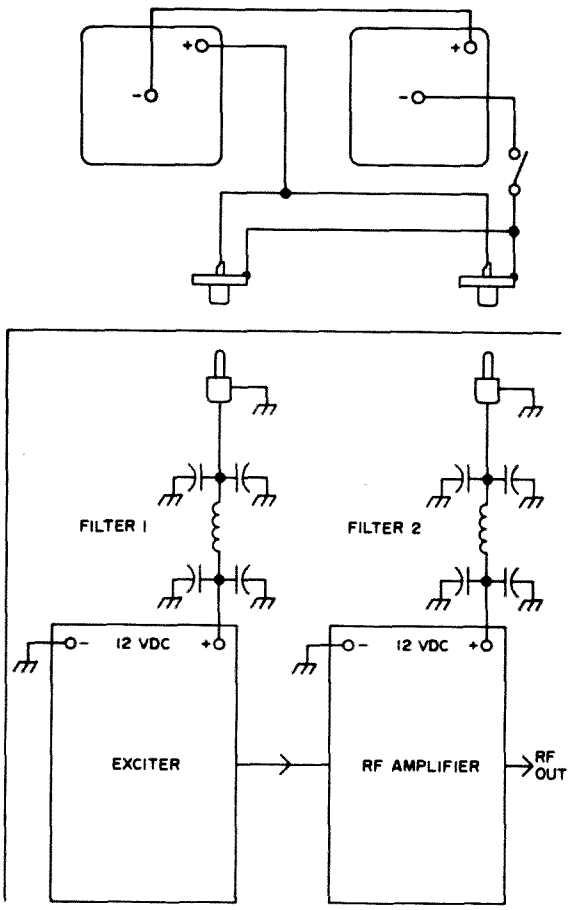

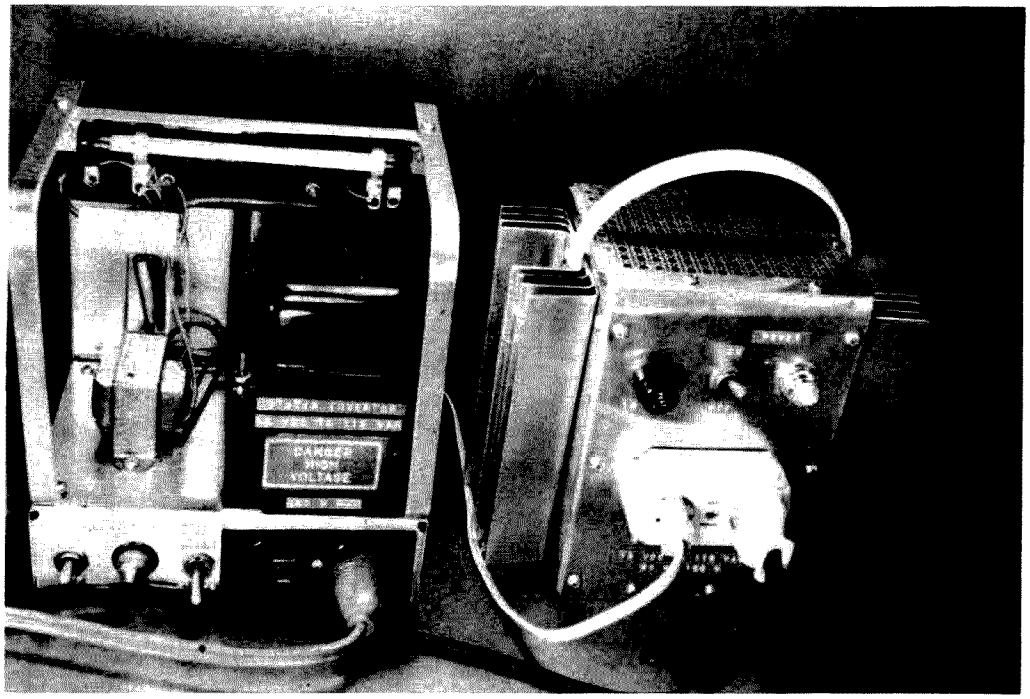

Fig. 9. Battery lead filters.

So a piece of copper-clad was put down under the two units as shown in Fig. 9 and the two filters installed. Perfect! No rf could be detected at all at any place on the batteries. Note that *two* filters are now present across any feedback path through the batteries and their leads.

There still exists possible voltage field and magnetic field feedback paths between the rf final and the exciter, but that's another story. The battery lead feedback path is not eliminated. And at least one thing shows up in favor for the solid state deives. There is only *one* wire in which to put a filter!

Complete power system in operation. Unit B to the left – Unit A to the right.

PORTABLE HOUSE POWER

Adding a 12V dc to 110V ac 60 Hz static inverter to the equipment list of the amateur experimenter will increase the versatility of his station to a degree that makes any reasonable labor in this direction worth while. The two units, presented here, are intended to be used together and, with a 12V auto battery as primary power, have the necessary output capability to supply 110V ac 50–60 Hz to an entire 150W station, including the receiver. There are no communications equipment modifications required. Just plug the transmitter and receiver into their receptacles and turn on the inverter switches.

Unit A has an output of 90W and Unit B 200W. Both outputs are 50–60 Hz symmetrical square waves. It might be well to note at this point that the peak value of a 110V ac, rms, square wave is 110V, while the peak value of a 110V ac, rms, sine wave is 155V. This difference in peak values will not be noticed in resistive loads such as tube filaments, but will cause lower voltages in rectifier circuits that depend upon capacitor input filters and voltage doublers. The output frequency of Unit A is 50–60 Hz and is not affected by any type of load, resistive or transformer. When Unit B is in the slave mode, it is driven by a signal from the output of Unit A. The frequency will be the same as Unit A and will not be affected by loading. When operated in the master mode, it converts to an oscillator tuned to 60 Hz which

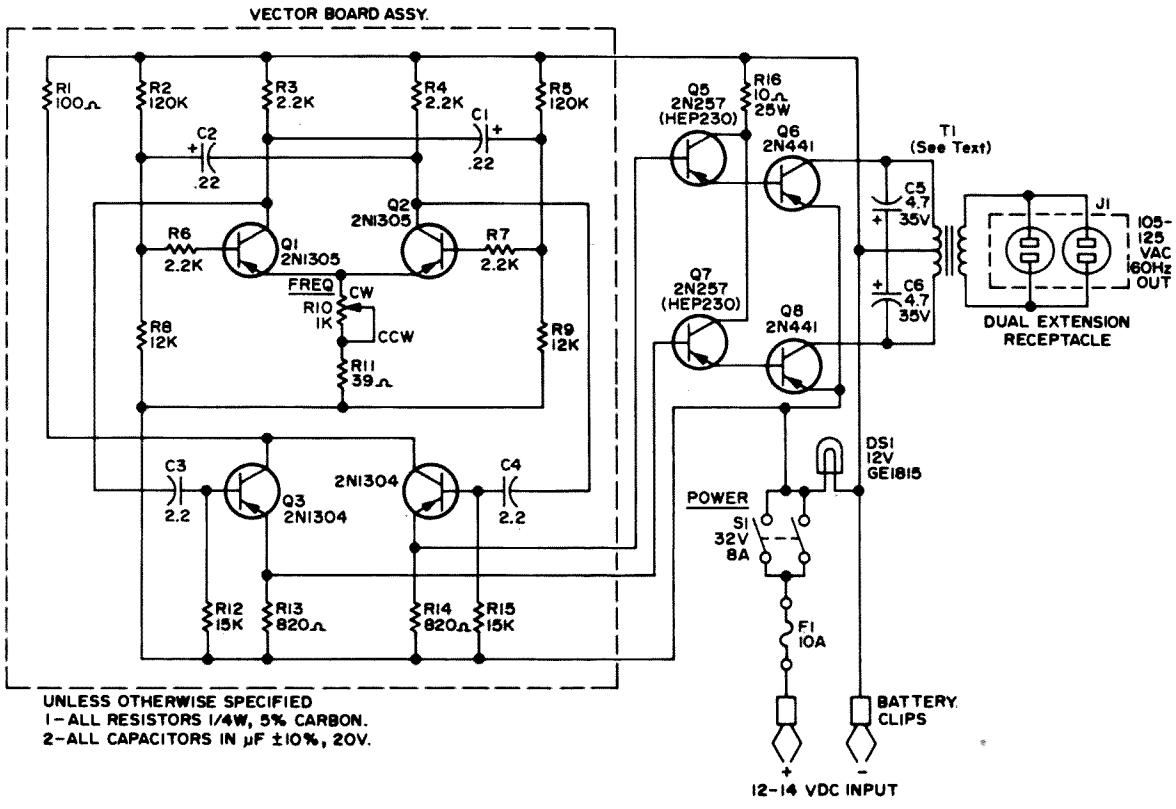

Fig. 1. Unit A inverter.

produces an output without external drive. It will maintain this frequency very well when providing power for resistive appliances, such as soldering irons and lamps, that require inputs within the range of 50 to 100W.

Both units make excellent projects for amateurs with an urge to use their oscilloscope and to gain experience with transistor power switches.

The fundamental problem in making our high power square wave is to switch the 12V dc from one side of a center-tapped transformer primary to the other at a predetermined rate. If the secondary has 10 times more turns than the primary, the output of this winding – neglecting losses – will be a 120V ac rms square wave. Using a transformer as a tuned circuit element of a 60 Hz transistor oscillator solves this switching problem very nicely, so long as its load is not of the type that will pull the frequency – for example – equipment containing input power transformers. To eliminate these load effects the circuit shown in Fig. 1 was developed. We shall call it Unit A. It consists of a 60 Hz free-running multivibrator, Q1 and Q2, whose outputs, phased 180° from each other, are fed through buffer amplifiers Q3 and Q4 to the switch drivers, Q5 and Q7. Q5 and Q7 are over-driven to square the waveforms and to supply the 0.5A input signals required by the power transistor switches, Q6 and Q8. This high current is necessary to keep Q6 and Q8 in saturated conducting condition so that very little voltage is dropped across the emitter to collector junction. This condition reduces internal heating (P=EI) to the minimum possible. Q6 and Q8 alternatingly snapping off and on changes the current flow through the transformer primary, which is coupled to the step-up secondary, and produces a 110V ac output.

While trying to power a receiver and a transmitter from the same inverter, I uncovered a formidable voltage regulation problem. To get around this trouble another inverter was constructed that would carry the heavy transmitter power, Unit B. This circuit, Fig. 2, was made for high

current, and its switches consist of two parallel connected transistors, Q9 and Q10 in one, and Q11 and Q12 in the other leg of the transformer primary. When the mode switch S3 is in the slave position, these transistor pairs are driven by a centertapped 6.3V filament transformer, T2, which is excited by the square wave output of the frequency controlled inverter, Unit A. When the mode switch is in the master position, Unit B changes from an amplifier of a sort to an oscillator tuned to 60 Hz. Current limiting resistor R17 is switched to a voltage divider, furnishing forward bias to the power transistor switches, and at the same time, the output of the inverter is switched to the primary of T2 at the proper phase to sustain oscillations. The mode switch is a refinement that adds flexibility to the unit by allowing it to operate independently of any outside circuitry.

The construction of the inverters is not difficult. One of the reasons is that the physical appearance of either one can be anything that pleases the individual. Nothing is critical as far as pickup or lead length is concerned. However, we are using relatively high current, five to twenty Amperes, so any long wire runs to the power circuits should be heavy gauge. It is very easy to drop a couple of volts through the leads connecting the inverter to the auto battery if they are not much larger gauge than necessary to protect them from overheating. One volt drop at the input results in ten volts less at the output. It is recommended that jumper cables of the type that are made for starting one car from another's battery be used for the input leads.

Inverter Unit A was constructed around a chassis that just fits its transformer. The case is made of solid 1/32-in. thick aluminum with the back and top the perforated type. The front panel was doubled so as to provide a firm mounting for the power switch, S1, fuse, F1; indicator lamp, I1; and receptacle, J1. A piece of belt looped over the top makes a convenient carrying handle. The multivibrator and buffer circuits, because of the nature of their parts, are assembled on a Vectorboard. These circuits, containing Q1 through Q4, are

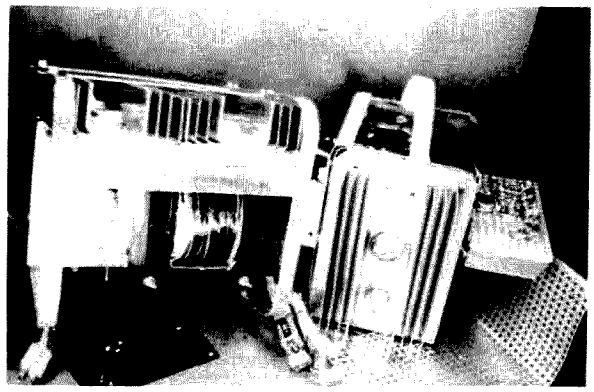
neatly arranged on a 4¾ in. by 2¾ in. piece; a size that provides room for flea-clip tie points around its edges. After this assembly is wired, it can be tested before it is mounted above T1, by the use of clips that hold it just inside of the back cover. The switch drivers, Q5 and Q7, generate no heat, but for the sake of a place to put them each one is mounted on the bottom of the heatsink containing its switching transistor, Q6 and Q8, respectively. These transistors are spaced at 2 in. and are centered as well as clearances will allow.

The heatsinks are assemblies of scrap aluminum, each consisting of three pieces of 1/32 in. and one piece of 1/16 in. thick material. All are 6 in. long and are bent into "U" channels with legs 1¼ in. high and widths of 3¼, 2 5/8, and 1 3/8 in. The narrowest is made of the thicker material. These channels are nested together, being sure that each one is flat against the other. The transistor mounting bolts hold the pieces together. Homemade heatsinks require a surprising amount of material and make commercially available ones very attractive.



The transistors are insulated from the heatsinks by using mounting kits. T1 is a TV transformer which has a low voltage complement of two 5V rectifier filament windings along with one of 12.6V, center-tapped. One end of each 5V winding is connected to opposite ends of the 12.6V winding. They are phased so that when the transformer is energized the voltage measured across the three series connected coils is 22.6V ac and 11.3V ac from each end to the centertap. This 22.6V winding is used as the inverter's primary and is connected to the switching transistor collectors. The 110V winding (the original input winding) is used as the inverter's secondary and is connected to the output receptacle.

The rest of the leftover high voltage outputs are separated and fastened out of the way to flea-clips along the outer edge of the Vectorboard. The potential of these wires is very high, about 700V ac, so keep clear of them when the inverter is operating. TV transformers of this type are not uncommon and save lots of work winding a

useful primary. If a TV transformer of this type cannot be found, then one must be modified in the manner described in Unit B's construction procedure for T3.

Unit B has a different layout because a 7 x 5 x 2 in. chassis happened to be laying in front of me at the right moment. The heatsinks are identical to those of Unit A, with the transistors equally spaced from each other and the edges. These transistors are bolted directly to the heatsink surface without insulators. This allows better heat conduction and not too much added construction difficulty, keeping the heatsinks insulated from the rest of the chassis. The two heatsinks, one containing Q9 and Q10, the other Q11 and Q12, are bolted 1/8 in. from each other to a 1¾ x 7 in. piece of insulating board running across their top and to a second piece across their bottom. Large clearance holes are provided for the lower bolts through the rear side of the chassis, and the lower insulating board is drilled and bolted in this location. The heatsinks will then be held firmly vertical. R17 is fastened to the inner side of the top board along with a curved shield over it for protection. Roll bars made of 3/32 in. thick metal are run around the outside edge of the unit to keep the heatsinks from coming into contact with any conducting obstruction and to be used as carrying handles. These bars are also tied together with two ½ in. strips of insulating board across the back where the heatsinks might be bumped. The power switch, S2, is a DPST with both sections connected in parallel so it will carry the input current. This switch; the mode switch, S3; indicator lamp, I2; and receptacle, J2; are attached to the front of the chassis along with a liberal number of labels and high voltage signs. The input leads enter the back of the chassis, where the fuse is also placed, and T2 and T3 take their place on the top surface.

T3 is a modified TV transformer. The primary current requirement for Unit B is too high to permit the use of the existing windings. To modify it the end bells are removed, the filament windings unwrapped, and the high voltage leads cut

Unit B – top view (left) and Unit A – side view (right). The T3 winding seen is ½ of its new primary. The Vectorboard is tilted outward to show its inner side.

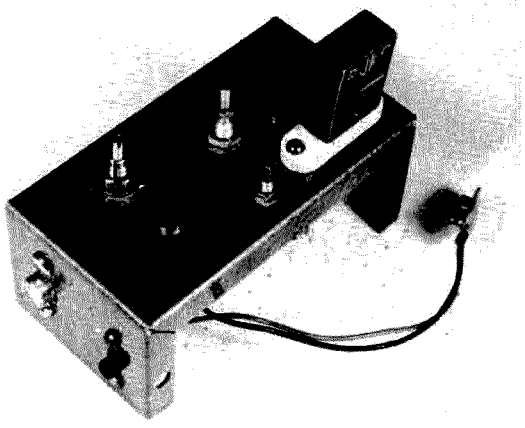
short and insulated, all without disassembling the core. There is very little chance that the filament winding will not be the first layer. When taking off the original windings, count the number of turns of the coil of a known voltage, so that when the new primary is wound, 23V of turns can be replaced. For example, if the 5V coil had eight turns, for 23V you would need 8/5 x 23 which equals 36.8 turns. Rounding this figure to the nearest half will not affect the end result. Number 14 gauge enamel wire is used, and it is divided into two pieces, each long enough for one 11.5V coil. The length of these pieces is determined by wrapping a short wire around the coil once and measuring it. Multiplying that length by the number of turns required will give the approximate length. Allow about three feet for safety. The sharp edges of the core are covered with masking tape, especially between the coil and the core, and the wire is slid under the core and around the coil the required number of turns. It will not take more than two layers, which are separated by brown paper. There will be ample room, because all kinds of high voltage insulation will have been removed along with the filament windings.

After the coils are completed, jam pieces of cardboard between the coils and the core to hold the wire in place. The four ends are marked so that you will know which two are going to make the centertap. Energizing the transformer from its normal primary is advised before the leads are cut to size. This way any errors that might

have occurred may be detected and corrected by adding or removing wire. The ends of this primary connect to the power transistor collectors and the centertap to negative power lead. The 110V winding will become the secondary and connects to the receptacle.

Before applying power to either unit some precautions should be observed. Be sure that your auto electrical system is able to supply the required current. To give you something to work from, my 1964 Chevy shows no ill effects. Be constantly on the alert for overheating transistors. Any large temperature difference between the heatsink and the transistor should be regarded as overheat as the heatsink is supposed to lead all normal heat away from the power transistors. Excessive heat will ruin these transistors and is an indication that they are not being driven "on" hard enough. Voltage transients will also cause damage, so do not operate the inverters with an unloaded output.

Before you power Unit A, R10 should be set. If the frequency of the multivibrator was not set when the Vectorboard assembly was tested, turn R10 fully CCW and back 1/8 of a turn. Connect the input power leads directly to the battery terminals. Plug a 50W lamp into the output receptacle and place the power switch on. The lamp should glow brightly. Check the power transistors for overheat as quickly as possible. Check the output waveform with your oscilloscope. It should be symmetrical and square as a box and have the frequency of 50 to 60 Hz. Touch up R10 if necessary to change the frequency, but try to keep it as near CCW as possible. If heat is noticed or the wave is unsymmetrical change Q1 with Q2 or Q3 with Q4 to balance the drive. Plug a second lamp into the receptacle, a 40W one. If both lamps are glowing brightly and there is no excessive heating, Unit A is ready for use.



Before powering Unit B, adjust the taps on R17. The tap near the S3 end of the resistor should be located 1Ω from that end, and the top near the positive end should be positioned 6Ω from that end. Connect a 100W lamp to the output receptacle, connect the power leads directly across the battery terminals, set the mode switch to "master", and place the power switch on. The lamp should glow brightly. If it does not glow, the feedback from T2 is most likely out of phase and reversing its primary connections will correct the fault. The tap at the positive end of R17 can be readjusted so that the lamp will glow immediately after the power switch is placed on, but as close to that end as reliable operation will allow. Set the mode switch to "slave" and the lamp will go out. Plug the drive cable into Unit A's receptacle along with a lamp. When Unit A is operating, the lamp in Unit B will glow. Bring the lamp load up to 200W and check for transistor overheat. To reduce any excess heating, adjust the tap on R17 near the S3 end closer to that end. This will increase the signal to the power transistor bases. The output of Unit B should be a duplicate of Unit A, when in the slave mode. When in the master mode the output is still square and the frequency very close to 60 Hz.

Some possible changes to the components of the system that have been tried and might be of interest follow: First, the switch drivers of Unit A are powerful enough to drive two parallel connected 2N441 transistors. This will raise its output capability to almost that of Unit B, 180W, providing T1 has a large-gauge primary. Also, the drivers will handle four diamond power transistors parallel connected in each primary leg. What the output capability will be depends upon the quality of the transistors, but should not be less than the original 90W. Unit B does not require parallel connected switches or modified transformer if it will not be called upon to deliver more than 100W. I have not tried either unit at frequencies other than 60 Hz but do not see why changing the transformers and multivibrator will not allow both units to work well at 400 Hz. The ultimate application of the idea presented here will come when some homebrewer designs his transmitter's power supply so that it may be plugged into his 110V ac home outlet, or into his auto's 12V dc system without fuss of any sort.

HOT CARRIER DIODE CONVERTER

For several years most of my hamming has been done with a three-band transceiver. Now, that's fine most of the time, but then there are times when I get to wondering what's going on on the other bands. So I began to look around for a good, simple, economical solution. It was during this search that I ran across the hot carrier diode.

One of the claims made by the manufacturer – "The hot carrier diode's performance . . . can be described as closely approximating the ideal diode" – started me to wondering just how well they would work in a 15m converter. So four of them were purchased, and the converter described here is the result.

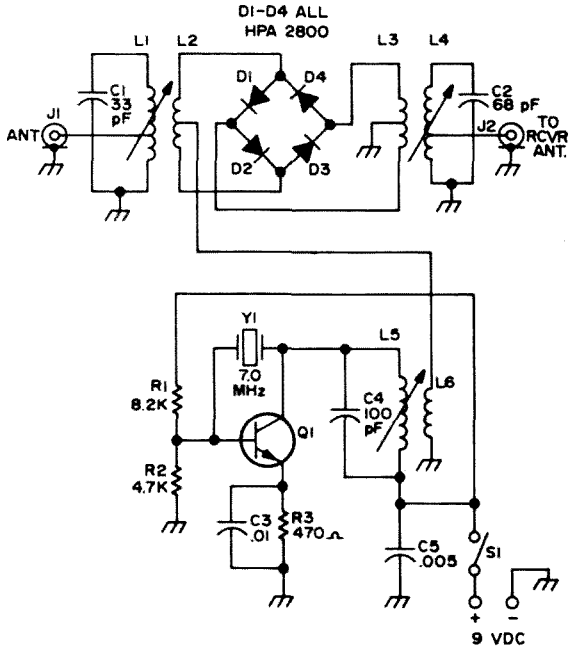

Fig. 1. Circuit of the 15m converter.

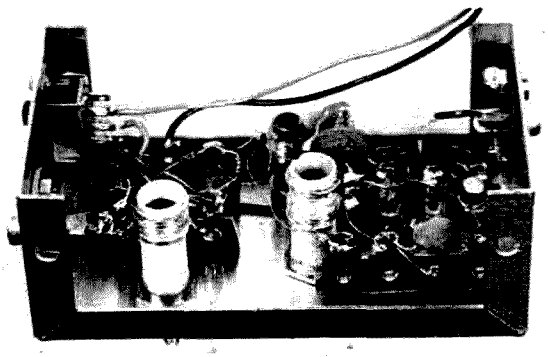


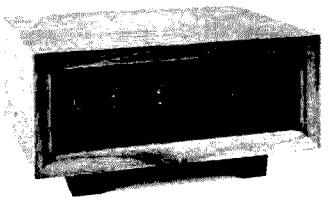
How do they work? The fantastic claims made for them are no exaggeration. They make excellent low-noise mixers and there is very little loss of signal. Consequently no rf amplifier is necessary. These diodes also possess a large dynamic square-law range which helps considerably with cross-modulation problems. When you add economy and simplicity to these advantages, what else could one want in a converter?

The particular diodes used in this converter, HPA 2800s, are made by Hewlett-Packard and are available from them for less than a dollar each. If you don't know where your nearest Hewlett-Packard distributor is, write directly to Hewlett-Packard, 620 Page Mill Road, Palo Alto, CA.

Circuit Description

The four diodes, D1–D4, are arranged in a balanced circuit. Both the input and the output are tuned, the input to 15m and the output to 20m. Because the input and output impedances of the detector arrangement are rather low, link coupling is used to couple to these tuned circuits.

The local oscillator is straightforward in every respect. It uses a 2N706 along with a 7 MHz crystal. I used an old FT243 type because I happened to have it. If you have a good active crystal in another type of holder, use it. Of course you will have to change the crystal socket to fit your crystal. The collector of the 2N706 is tuned to 7 MHz with a 3/8 in. diameter slug-tuned coil.



Construction of the Converter

The hot carrier diode converter is built into a small minibox (Bud CU-2101-A). Take a good look at the photograph and you can see the arrangement of the parts. The oscillator components are mounted at one end and the diodes and associated parts are at the other. All of the small parts are mounted on terminal strips. No socket is provided for the transistor. It and the diodes are soldered directly to the terminal strips. Use caution in soldering these devices in place: Too much heat will destroy them, and quickly. My method of doing this is to solder all other parts in place leaving these until last. Be sure you observe the polarity of the diodes.

Antenna coil L1 consists of 17 turns of 28-gage enameled wire close-wound on a ¼ in. slug-tuned form. It is tapped 5 turns from the bottom. L2 consists of 4 turns of 28-gage wire wound over the center of L1 and is centertapped. Both the output and oscillator coils are wound on 3/8 in. slug-tuned forms. Output coil L4 is 11 turns of 26-gage wire tapped 3 turns from the bottom. L3 is 3 turns centertapped wound over the center of L4. Oscillator coil L5 is 30 turns of 30-gage wire close-wound. L6 is 5 turns of 30-gage wound over L5.

I used RCA phono connectors for the antenna as well as output connections. If you prefer coax connectors you will have to use a larger box. The power switch is a miniature slider type. The converter is powered by a 9V miniature transistor battery.

SOLID STATE

DIGITAL CLOCK

Adjustment and Operation

Connect the converter output jack to the receiver (or transceiver) with a short shielded cable. Connect an antenna and the 9V battery. With the receiver on and tuned to 14 MHz, turn the converter power on and you should hear the second harmonic of the crystal oscillator in the converter. You might have to tune slightly to find it. If you don't, adjust the slug in the oscillator coil until you do. With the oscillator working, tuning higher on the receiver should bring in 15m signals. Peak L1 and L4 for maximum signal strength.

Using this little converter with a National NCX3 brought surprisingly good results. DX signals come in like locals. For the price and labor involved, it's a little jewel.

Wood Dale IL 60191

RTL DECADE AND DRIVER

There have been numerous articles using inexpensive RTL (resistor - transistor - logic) integrated circuits in frequency counters and in digital volt-ohmmeters. A good friend, Joe WA9CGZ, built the digital volt-ohmmeter from a magazine article[1], and, after making some changes in its circuitry (to improve its drift problem), brought it over for me to try. I was favorably impressed, but it left me cold in one respect. It had "idiot lights" for readouts, as do all the other frequency counters I've seen in the ham magazines. What do these flashing lights do? They get your eyeballs sore from jumping up and down and left and right while trying to follow the reading. I don't know about some people, but I was trained at a young and tender age that we read from left to right in a straight line. It's so much faster and easier.

To get back to Joe's voltmeter, I decided to build one, but with a different readout method. After looking over the many types (7 segment, projection, and others) I decided that the old gas-discharge numeric indicator was still a good performer, and so I chose it. As can be seen from the photograph, this type of tube comes in varieties of sizes and shapes. They are manufactured by National Electronics, Raytheon, Amperex and others. Lately these tubes have been appearing on the surplus market, but as it says in the back of *73*, Caveat Emptor! The NL-5750 is about the least expensive of indicator tubes on the market, and is stocked by Newark Electronics in Chicago as well as others.

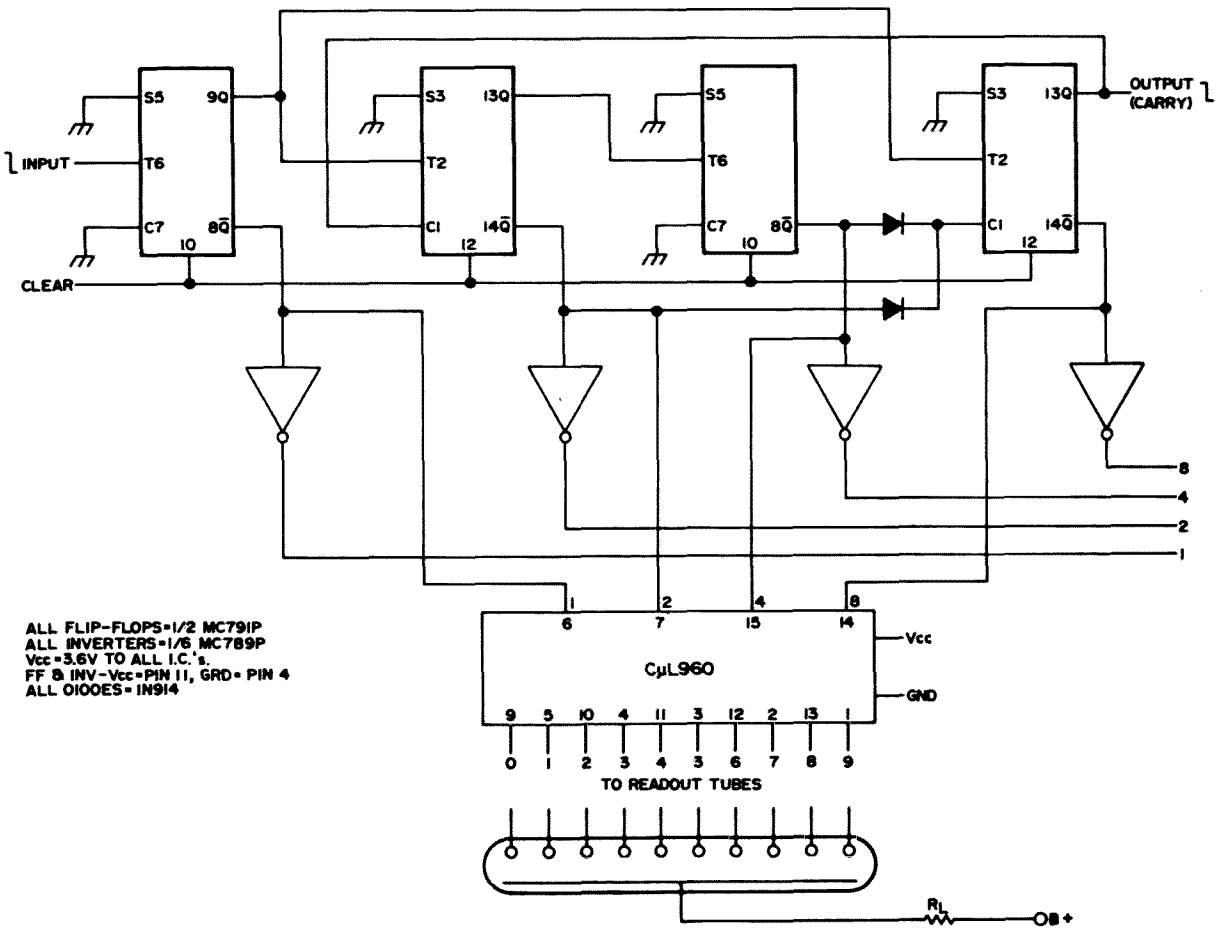
There are disadvantages, of course. (You want to have your cake and eat it, too?) The first is cost. These tubes do cost more than ten pilot lamps; however, most of the tubes are rated for 200,000 hours of service. If ten long-life lamps were used, then the lamps would cost more than the tubes.

Front view of the DVOM using the decade divider and driver discussed in article. Several types of gas discharge indicator tubes are on top. The one on the right is the type used in the DVOM. The cabinet shown is by Justin.*

The second disadvantage is that at least 170V dc is needed for the gas discharge tube. In the case of the voltmeter mentioned above, this was not a problem since the voltage was already there. Since the tubes draw only 2 or 3 μA each, it isn't difficult to get one way or another.

Now to get a working circuit. In looking over some of the circuits used by others, I found that several different binary counting systems were used (there are many types – gray, bi-quinary, excess three, and more); however, these didn't have much appeal because of the difficulty in decoding. For those not familiar with binary counting, let's just point out that in the binary counting system we count with the base two instead of base ten as in our familiar decimal system.

*Justin Inc.
2633 North Lee Avenue
So. El Monte CA.



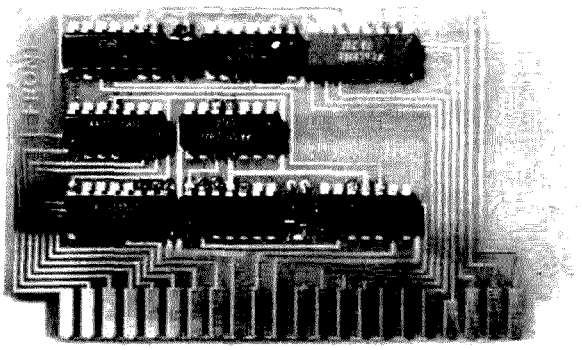


Fig. 1. Notes: All flip-flops ½ MC791P, all inverters 1/6 MC789P, Vcc is 3.6V to all IC's, F.F. & Inv. – Vcc Pin 11 – gnd pin 4, all diodes 1N914.

So we have to change the binary numbering system to the decimal system. This can be done with discrete components (diodes, resistors and transistors), but this costs as much as using a single integrated circuit. The single IC route was chosen for simplicity; the one used is made by Fairchild, and is completely compatible with RTL ICs. This choice limits our binary code selection since the μL 9960 requires an 8421 BCD (binary coded decimal) input. This is a common code used in the industry; I'll tell you why later. All that is needed now is a Mod 10 that has a 8421 BCD output.

Since four flip-flops can count to sixteen, we can permute them to count only as high as ten. As can be seen from the schematic, the outputs of the Mod 10 come off from the "NOT" side of the stages because the 9960 requires negative logic. A word about the flip-flops . . . MC791P's made by Motorola were used. These have the same pin connections as the widely used MC790's, but are capable of the greater output needed here. Do not use the MC790!

I felt that a BCD output could prove useful in the future to drive a digital printer so it is necessary to bring only the four leads from the Mod 10 out. This could be done directly off the counter, but is not desirable because the added capacitance of long leads could pick up stray rf and cause false counting. The best way is to buffer the output and this is easily accomplished with another IC, the MC789P hex inverter. By connecting the inputs of four of the inverters to the 8421 negative logic side of the Mod 10, we have a buffered output of 8421 positive logic. The remaining two inverters are not used. The positive logic output, which is more commonly used than negative logic, will drive 5 RTL or 3 DTL or TTL loads.

I built two identical circuits on a double-sided printed circuit board[2] that plugs into a double 22-pin connector. I used this method

Front view of the double-sided PC board used to hold two decade dividers and drivers.

to save space and provide greater ease of repair should it ever become necessary (the remainder of the voltmeter was built on two more boards of the same size). Hand-wiring of the circuit can be used, of course, but I recommend the plug-in method in either case.

By cascading as many of these stages as you desire, you can make a frequency counter with the addition of a time base and appropriate gating. Just look over the circuits of frequency counters that have appeared in magazines in the last couple of years. If it uses RTL, chances are you can substitute a circuit for the one used and have an easier time reading out the answer. If you feel that a buffered BCD output will never be necessary, then omit the inverter stage.

Happy counting.

...W9SEK

Glossary

Positive logic – Where the logical "1" is more positive than logical "0".

Negative logic – Where the logical "1" is more negative than logical "0".

Modulo (Mod) – A counter circuit. The number indicates how many pulses are counted, i.e. a Mod 10 counts 10 input pulses. The output occurs on the 10th pulse. A Mod 5 will count 5 pulses, etc.

Permuting – A means of providing a feedback path to stages into counter to force it into desired state.

A POWER-SUPPLY SPLITTER FOR LINEAR IC'S

In a previous article, two dual regulated power supplies were described for use with the new linear IC's, which require ±6V or ±15V.[1] While the dual supply approach is not a bad one, the method herein described has several advantages. By plugging this "splitter" into any existing regulated power supply, a centertap is electronically created which will stay midway, voltage wise, between the plus and minus terminals. This centertap will stay at the midpoint even if current is drawn from it, and will stay at the midpoint even when one varies the supply voltage. This relaxes the requirement of extremely good supply regulation, as most linear amplifiers are more tolerant of supply voltage changes if the positive and negative voltages change equally.

The splitter is built on an etched circuit board, with a dual male banana-pin plug mounted on it for direct connection to one's regulated supply. Three binding posts are similarly mounted on the board and serve as the output terminals. The splitter is shown in use in the photo, operating with a regulated power supply I have previously described.[2]

The original circuit of a similar splitter appeared in one of the engineering magazines, and as such was not exposed to ham readership.[3] Also, the original circuit used semiconductors that are either too expensive or hard to obtain for hams. By use of economy transistors, the price of parts of the splitter herein described is a fraction of the price of the parts required to build the original. Two type-numbers are given for each semiconductor in the circuit of Fig. 1,

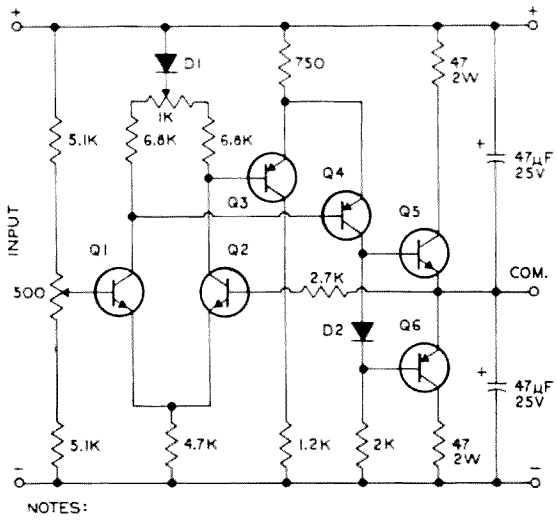

Fig. 1. Power supply circuit.

the Motorola HEP numbers being the more available types. The other type-numbers are perhaps more readily obtainable by those hams who work in the electronic industries and regularly deal with large industrial electronic supply houses.

The etched circuit board and the parts placement on it are shown in Figs. 2 and 3. Note that the MJE 370, MJE 520, HEP 245 and HEP 246 are in what Motorola calls a "Thermopad package." Heat dissipators may be easily and inexpensively made for these transistors out of small "U"-shaped pieces of aluminum or copper sheet, as shown. The circuit board was laid out to fit Beckman 78PR type trim-pots (cermet).

Once the parts have all been soldered to the board – an easy hour's effort – you're ready for testing. I think it best to try the splitter on a current-limiting type supply, such as that described in reference 2, with the current limiting set to about 50 mA.

The regulated supply feeding the splitter is set to 24V, so that the output of the splitter will be ±12V. The reason for calibration at this voltage is that it is in the middle of the useful operation range (10–40V input) and also it fits the 12V requirement for one of the *best* operational amplifiers that I have found – the General Electric PA223. The splitter will draw about 15 mA with no load; if it draws considerably more, check for soldering errors or faulty semiconductors. The 500Ω trimpot is adjusted until the plus and minus outputs are equal. The setting of the 1000Ω trimpot is more tedious; the setup is shown in Fig. 4. Offset of the centertap from a true "split" is indicated by the VTVM as the input voltage

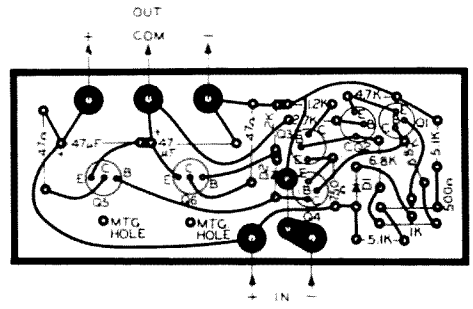

Fig. 3. Circuit board, parts placement.

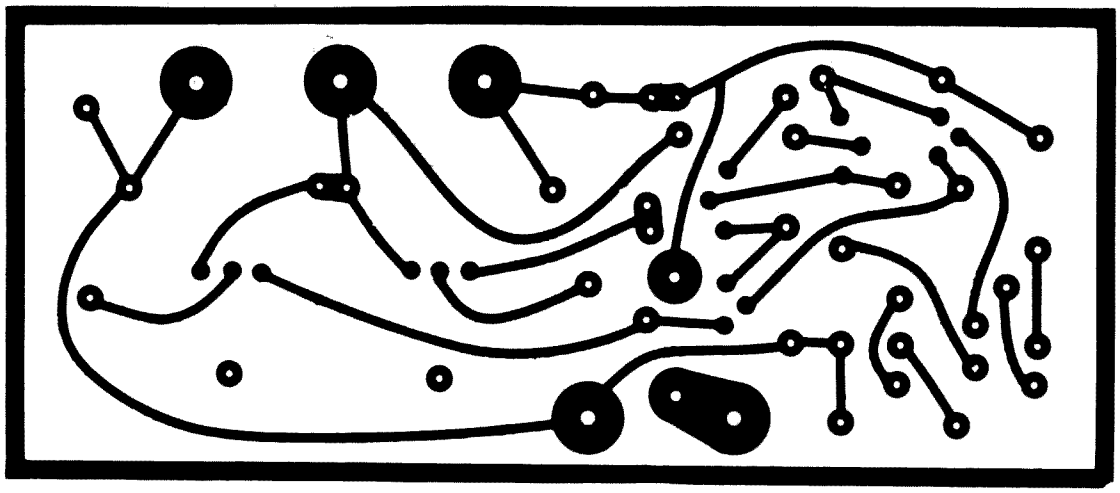

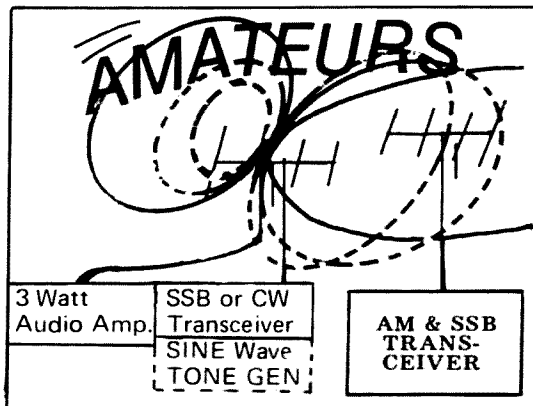

Fig. 2. Circuit board shown copper side up (80% reduction).

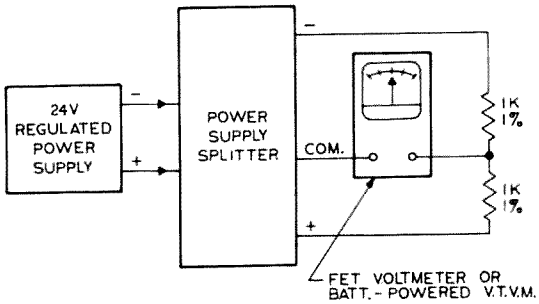

Fig. 4. Test setup for setting adjustment pots on splitter.

is varied from 10 to 40V. The offset is corrected by adjusting the 1K pot, and again sweeping the input voltage from 10 to 40V. This procedure is repeated until the best approximation to perfect splitting is obtained.

The splitter can deliver up to about 100 mA through the centertap, but this should rarely be necessary, since the main current drawn by operational amplifiers and other linear IC's is between the plus and minus terminals. The splitter has been used to power Fairchild μL709's and National LM201's on ±15V, General Electric PA223's on ±12V, and General Electric PA238's and RCA CA3029's on ±6V, all with success. As the world of linear IC's expands, this simple power supply splitter may easily become the handiest piece of bench equipment you own (next to the basic regulated power supply, of course).

I wish to thank Russ Wolfram W6ERX for his help in developing the circuit from its original form to the amateur version shown. Circuit boards and kit of parts are available from A.R.S. Enterprises, P.O. Box 555, Tempe AZ 85281.

LETTERS

(Continued from page 12)

cerned, who had six children to support, had been hauled into a Cleveland court for wearing an American flag on the seat of her pants, and with the suspension of her subsequent $1000 fine and thirty day jail sentence, had been properly humbled (humiliated) to the point of telling the judge, meekly, " . . . Yes, she thought it was a pretty good government, after all." Obviously this situation is emotionally, socially, and politically supercharged – it is much deeper than the level at which Mr. Russell chose to use it as a ploy for the introduction of his pro-League argument. Yet this is exactly what he did, i.e., use the words of a troubled welfare mother as a good example of how we ought not knock our "good government," or our good League. This is nothing but patent – and potentially dangerous – malarky. This kind of thing belongs nowhere in amateur radio – a realm of technical, not social, investigation – let alone the editorial pages of *QST*. Yet, there it was, in black and white. I wrote to ARRL in protest. My letter was not printed in *QST*, though W8BU had had a *second* letter of his printed as the first letter in the correspondence section of the *same November issue*! Check this out (page 88) if you do not believe me. Where does this man get off? Does he own the ARRL? I am an ARRL member, Extra Class, etc., just as W8BU is. How does he, or anyone, rate *two* letters in one issue, one of them printed as an editorial, no less, to my *zero* letters – especially when one of them is untenably political and potentially divisive in its implications? The ARRL would not answer me on this – John Huntoon told me in his answer to my letter that I had misinterpreted W8BU. I ask, what is there to misinterpret? It is all there in print, in *QST*. Moreover, *no* letters protesting W8BU's ill-considered stand were printed – while letters supporting him were, e.g., one by K8MMH/9, of Buffalo Grove IL, a personal friend of W8BU (by the way, try to find Buffalo Grove on the map). Yet I *know* protest exists – I protest this. WA9SZQ protests it. I brought this issue to the attention of the ARRL Hawaii SCM, KH6BZF, one night on twenty meters and he admitted, after I had stood by for him to read the editorial, that he felt like hanging his life membership plaque upside down on the wall of the shack. What I want is for all ARRL members who feel likewise – and I urge those of you who haven't read W8BU's editorial to do so – to write their Division Director, as well as Headquarters, demanding the retraction of this editorial. That's all I want, that, and that the amateur world know there are people who disagree with W8BU and ARRL on this and were not allowed to express that disagreement in the same forum that bred it – the pages of *QST*. That's why I ask your help in printing this – injecting politics of any kind into ARRL policy is bad, but apparently ARRL has an even worse policy of not allowing dissent against its major blunders to be voiced. Let's get that editorial retracted!

Sgt. Peter Erk WA9TCR/KP4
Camp Garcia, Vieques, P.R.

Please tell me what the number '26009' under the date and price on front covers for the last couple of months means?

Really enjoy the magazine.

Dick Altman
San Francisco CA

Roughly half of 73's copies are sold on the newsstands and this is being handled by a national distributor. Newsstands keep track of magazines by means of the little code number on the cover. Right near the number you will find the insignia of the distributor, Ace News.

I thought you would like to know that 6 xtals for my TR-22 from KW Industries and all were OK even without a tune-up. They also delivered within a week including 2-way mail.

Jim Kirkgasser WA2ELA

This letter is a little negative feedback, and an offer to help.

The article in the August issue, "The 1926'er: The Ideal Crystal Oscillator,' may describe a fine oscillator that performs as claimed, but the "How It Works" is pretty far off base. In fact, it's down-right wrong. Some unsuspecting reader may believe the statement on page 116 that says the crystal provides 180° of phase shift. It just ain't so!! Maybe Bill Hoisington can't be objective about his own analysis, but the theory of operation given implies a basic misunderstanding of crystals and oscillators; his 30 years notwithstanding.

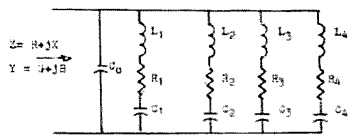

Fig. 1. Crystal unit equivalent circuit.

Control crystals have the generally accepted electrical equivalent circuit shown in Fig. 1. Ordinarily the first mesh is sufficient for analysis of the operation of the crystal unit. The extra branches account for the spurious mechanical responses that often affect the measured response. The impedance variation of a crystal unit near the principal mechanical resonance is shown in Fig. 2. There are two frequencies at which the reactance is zero, or where the crystal resonates. (This zero reactance point is the classical definition of resonance); the resistance is very low at one and very high at the other. The lower frequency, at which the resistance is very low, is referred to as the series resonant frequency, and the higher frequency, at which the high impedance is seen, is referred to as the anti-resonant or parallel resonant frequency. Crystals operating on a mechanical overtone have a low impedance and appear to operate in the series mode. The impedance of the crystal unit is near zero and resistive. (The holder capacity or load capacity, Co, has minor effect when shunted by the low impedance series-tuned circuit.)

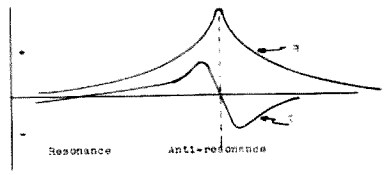

Fig. 2. Crystal unit impedance variation.

The fact that the oscillator circuit uses the crystal unit between collector and base does not mean the crystal provides 180° of phase shift. (In the Pierce oscillator, the crystal is between plate and grid, and I don't believe anyone claims 180° in that application.) So, if the crystal operates at series resonance with nearly zero reactance, how does it work? To explain the operation, I'll assume a qualitative understanding of the Clapp oscillator, and go from there. A typical Clapp oscillator is shown in Fig. 3; bias sources are not shown. At the lower frequencies, the capacitors Cbe, Cce, and Ccb may be physical capacitors augmenting the internal capacitance of the transistor. At higher frequencies the transistors internal capacity may be enough. In passing, note the similarity between the equivalent circuit of the crystal and L, Ct, and Ccb in the Clapp's resonant circuit.

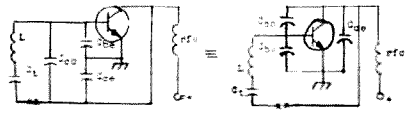

Fig. 3. Typical Clapp oscillator.

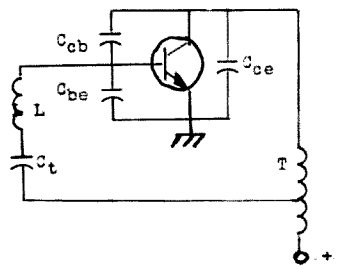

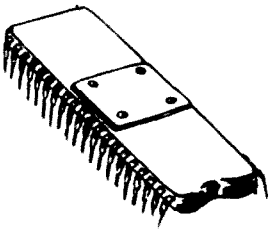

Fig. 4. Modified Clapp oscillator.

Generally, the oscillator designer can choose components compatible with the impedance levels required by the transistor. If such is not the case,

the impedances can be transformed one way or another to a suitable level. For example, an auto-transformer can be inserted at "X-X" to provide the

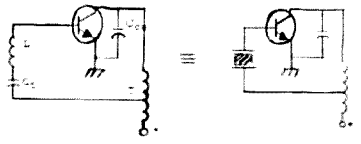

Fig. 5. Modified Clapp oscillator redrawn.

required impedance transformation as shown in Fig. 4. Now, if the circuit is redrawn without showing the transistor's internal capacities, and showing only the physical components, Fig. 5 results. If L and C_γ are replaced by the series-tuned circuit of the crystal, lo and behold we have the "Ideal Crystal Oscillator" sans bias. Now the crystal can be seen to operate in conformance with the laws of physics, and there is no need to demand the impossible 180° phase shift.

If the operation of the Clapp or Colpitts are not understood, let me know and I'll write a tutorial article explaining them and relating them to the real world.

LETTERS

Thanks for the Advanced Class Study Guide with my new subscription to 73 magazine. I passed my Advanced Class License Exam in Houston, Texas, August 21, 1972 (just two days ago) by using this book and by using Advanced Handbook by Howard Pyle W70E (Howard W. Sams book). Both books are excellent study guides.

Ben W. Thomas

Six meter activity is rare around here, especially 6 CW. I decided to brave the TVI with a good LP filter, and try to build up 6 CW activity.

I'll only run 60w with a 6 element beam, until I see how the TVI is, with channel 2 only 25 miles away. Then, maybe more power if things work out.

I will welcome any skeds with anyone looking for Iowa on 6, CW preferred, but will also work AM.

Robert Lucas WAØDXZ
Iowa City IA

Recently I ordered parts for your current frequency counter project from your advertiser, Circuit Specialists. They do not carry some of the items, but because of my remote location, they shopped for me outside of their own store in order to send me the whole kit.

Any magazine with that kind of advertising just *has* to be something special!

Same goes for the advertiser . . . give them a discount rate!

Leonard C. Nelson KW6EG
Wake Island

First of all I would like to tell you how much I enjoy 73, and look forward to every issue. Please find enclosed payment for the next 2 years. The purpose of this letter is to point out something I read in your August 1972 issue covering the recent expedition to Navassa Island. The comment was made that KC4DX did not leave any signatures or such painted on rocks and buildings, which I'm sure they didn't. However, it was also stated that in 1958, KC4AF did not leave any signatures. Upon looking through some old CQ magazines trying to find another article, I ran across the June 1958 issue of CQ, and there on the front cover, as big as life, painted on the wall of Navassa Island, were the call letters W2NSD, which I have to assume were painted there during the KC4AF expedition. I did notice that on a similar picture of KC4DX that this wall had been painted black, or the picture painted over. Like I said in the beginning, I enjoy your magazine very much and this is not in the form of a complaint, only I do think an explanation is in order.

Keep up the good work, especially in WAØABI articles on the 50 MHz band.

Ted Hogan K4VAA
Cheraw SC

I was afraid that no one would ask. The fact is that rather than paint up the island, I chose the easy way out and painted up the photograph just for that cover picture on CQ. If you'll look closely at the picture, you'll see that I put in a shark swimming around the boat too. That was back when I was devious.

Wayne

I'm finally back in the land of infinite variety after a busy year at Harvard. Didn't get a chance to stop up and visit with you folks again so see you at the next Dayton convention if I get there.

About a year ago *The Milliwatt* announced two awards for the low power operator – DXCC QRPP and DXCC MILLIWATT for working 100 countries at the five and one watt power levels. Well, first QRPP DXCC goes to K4OCE for submitting proper QSL proof. I'm enclosing a photo of the award aptly displayed by my editorial assistant, Karen Thomas. We

still have announcement sheets for the awards upon request. I'm sure that the boys would appreciate getting an eyeball look at this DX award. If you can't use the photo, I'd appreciate getting it back. Keep plugging away up there old man. I envy you guys for your idyllic surroundings. These flatlands depress me something awful. But that's life, I guess.

Ade Weiss K8EEG/Ø
Vermillion SD

What? FLATLANDS? Maybe you should reevaluate your surroundings.

SSTV continued

niche on the neck . . . if it shows where it was filed, it is soft. And I understand also, this varies in individual tubes – like some 5FP7's might be "soft" and some "hard." VK3LM has all the info if you're anxious to have a tube reworked.

Does a Slow Scan station equipped with a camera have a justifiable need for a flying spot scanner? This is one question Clarence K6IV and I discussed recently during a brief meeting. The advantages of a camera are obvious, but what are the advantages of a flying spot scanner? Possibly heat dissipation and pre-focusing. Although modern cameras perform quite well with a mediocre amount of light, this still adds to the heat produced in the shack. (How often do you duck out for some cool air, eh?) And, if you show a group of different pictures, a portion of time is required for refocusing, so photos and a FSS under certain conditions could prove worthwhile. One method of obtaining these results (for those of you with Slow Scan cameras) is by the use of a snap-on adapter. A minibox (or other suitable enclosure) can be fabricated so pictures will slide in one end. The other end is cut to fit over the camera lens, and securely fasten to the camera in a light, tight manner. Then a couple of small pilot lamps are added in the box, pointing toward the picture area. (The physical layout of a "photo end of an FSS" is covered fully in the SSTV Handbook if you don't understand my brief description.) Since this home-brewed adapter uses all your existing Slow Scan transmitting circuitry, nothing else need be taken off or added onto the camera, as desired. It is quite possible Robot may come out with an accessory like this in the future, if sufficient interest is generated.

I'm sure most of you recognize the chap in the photo as K6IV. Clarence transmitted this picture of himself to JA3JEW, and this is a photo of the received picture. Not bad for a California/Japan QSO, eh?

Color Slow Scan is on the upswing. If you are operating color, drop me a line on your progress, ideas, etc. I will add it in the column and possibly we can expand the color SSTV horizons in the near future.

Readers have an obligation to sit down and write checks to as many advertisers as possible so they'll be back next month and we can bring you another whopper issue like this. The radio gear and parts will be a bonus to remind you of your support of a good cause. Reading time: 31 days.*

EDITORIAL BY WAYNE GREEN

THE NEW REGULATIONS
WAYNE'S VIEW

The heavy hand of an insensitive government has just dealt a cruel blow to the most exciting and fun aspect of amateur radio in many, many years. FM will never be the same.

It is sad to listen to the voices on the bands agreeing that, yes, the new rules do seem rather restrictive, but we can live with them. Sure, we can live with them. Man has shown himself to be eminently adaptable – able to live under almost any conditions, from Russian prison camps to the Inquisition.

But now, just as amateur radio has at last been staggering back from the blow of "incentive licensing," one of the last things we really need is to have a hysterectomy in the FM department.

THE GOOD PART

Many years late, the Commission has finally opened the 147 MHz segment of the two meter band to Techs. This move appears to have been purposely held up to try and sweeten the bitter pill of repeater restriction. It is the *only* major benefit from this otherwise negative and crushing report and order.

The other dim ray of light in the order was the relaxing of logging rules for repeaters. Much of the charm of this change was taken out by a reaffirmation of the need for detailed logging by everyone but repeaters. The Commission cannot, I believe, produce any substantial arguments to support the continuing of such logging. It is a hold over from the earliest days of radio and serves little purpose today.

THE BAD PART

The licensing of repeaters is now set up so that it is a great big deal just to apply for the license – and expensive. You have to have topographical maps to work out the average terrain – antenna radiation pattern charts, vertical and horizontal – diagrams of the entire repeater and control system (which has to be approved before each and every change) – provision for monitoring input and outputs of the repeater – a license for each and every control point – a license for the link – and a license for the repeater. At $9 per license, this can mount up rapidly.

Another disaster is the matter of monitoring. The new regulations are quite explicit in demanding continuous monitoring of the repeater input and output frequencies. This means that all but a few repeaters will have to be shut down when the control operators are asleep – when they are at work – on vacation – at the movies – playing cards – at a party – or (hopefully) with the wife. There doesn't seem to be any logical reason for this rule other than harassment and hamstringing of amateur repeater service since it is not difficult to provide safeguards which will shut down a repeater in the event of malfunction or funny business.

Let's take that to an extreme. Let's suppose that a berserk amateur has taken over the input of the repeater and is yelling porno and mayhem through the air – and he carries on for 24 hours straight before collapsing. A few of us with the patience to stick it out will have had something to talk about for years to come – the rest of us will have to use another repeater for a day. One or two sensitive souls may suffer a mental hernia from hearing such terrible things – providing they haven't ever been in a locker room or in the armed forces – or in college or high school during their lives. The rest of us will come out of it unscathed.

Direction finding gear being as it is, I doubt it will take very long to find the idiot. A recent case in New York hardly took any time at all before the repeater group was able to pinpoint the dingo who broke in on a repeater with hair-curling filth. Getting the FCC to do something about it was something else again, they seemed more entertained than alarmed.

The removal of the 220–222 MHz segment from repeater use blows the national agreed-upon plan for that band to bits. Pity, for the amateurs have displayed admirable cooperation in working out their own rules and allocations, complete with unofficial governing committees to keep everything in order. The FCC obviously was not impressed. The only logical reason that comes to mind for the shoving of repeaters out of the lower two MHz of the 220 band is to make room for the new citizens band which the Electronics Industry Association is buying for the Japanese.

The removal of repeaters from the 440–442 MHz segment of that band is another kick in the head. In view of the degree of organization that amateur groups have shown in the development of this band, it is difficult to understand this move. It serves little purpose and will be tremendously expensive to us.

Section 97,111c prohibits the crossbanding of repeaters. How come? There has been so little of this done that there is no way for it to have yet caused any problems. The two repeaters that I have used that had crossband facility (W1ALE in Concord NH and WA1KGO in Peterborough NH) never had any problems worthy of mention. Indeed, both provided a good deal of fun for those involved and made it possible for the six meter FMers to have a little window to talk with the two meter boys – and vice versa.

It is not practical to set up mobile FM gear for 52 MHz, 146 MHz, 220 MHz and 440 MHz all in one car. It is just too much. Too much investment – too much space – too much antennas – and too much to operate while driving. So what are we to do, have four different groups of amateurs using repeaters, with few ever able to talk with any of the other groups? Crossband repeaters with suitable controls are important, not only for fun, but particularly in times of emergency when it can be critical to be able to reach everyone.

Since repeaters are, under these new regulations, only permitted to operate in bands where all licenses above Novice are legal, there is no question of any operator being repeated out of his class of license.

I believe most amateurs will join me in thanking the Commission for finally opening up 147 MHz for Techs – for relaxing logging for repeaters – for permitting mobile control points for repeaters and remote base stations.

As for the rest of the regulations, they appear to be gratuitous harassment of the amateur service. They do not seem necessary. They are in some cases extremely harmful to the spirit of amateur radio. Little good can come from them.

ARTICLES NEEDED

While we do try and cover all bases in 73, the readership seems to prefer construction projects – particularly those using the newer ICs and transistors, so if you are building gear along

this line please keep in mind that many, many other amateurs would like to benefit by your experience.

By the way, when you send in diagrams using solid state devices, please be sure to include base diagrams to help those who will follow in your footsteps.

If your unit is of enough interest for a printed circuit board to be made available to the readers – or perhaps even a parts kit – we can arrange this with one of our advertisers unless you have sources of your own. Sometimes it is difficult to find all of the parts needed for a project, so we often try and work with an advertiser to make kits available.

If you are not sure about writing for 73, please send a stamped self-addressed envelope for *How to Write for 73.*

SAROC FM PROGRAM

As chairman of the FM program at Saroc, I am going to do my best to put on one whale of a show. It will be worth while coming to see, I guarantee.

The FM programs will start early on Friday morning and run all day Friday and all day Saturday until the big prize drawing Saturday afternoon. In addition to manufacturers on the spot to answer technical questions, there will be reports on FM activities around the country, an FM Symposium on changes we need in the FCC regulations – a report on the status of 220 MHz, and other topical subjects.

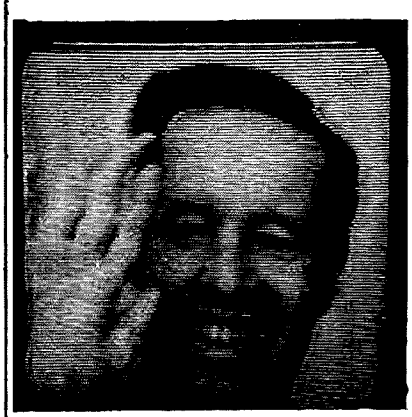
Representatives of repeater councils who will be at Saroc are hereby requested to drop a line to me so I can schedule you on the program. All of us want to know what has been happening in your area, so please bring a report. Repeater groups with slide shows or interesting FM oriented movies are also requested so let me know what you have available so I can schedule your part of the program and make arrangements for whatever equipment is needed.

FM will be the BIG deal at Saroc again this time, as it has for the last three years. Standard Communications is planning a lavish hospitality suite this time, complete with a built in Standard Repeater, of course. This custom has turned out to be a fabulous place for FMers to get together almost any time of the day or night to swap exaggerations about their repeater problems.

Several interesting technical papers will be read at the Symposium – and, if you have a paper that you would like to put on the docket, please let me know so I can get your talk scheduled.

The FM editors of all of the ham magazines will be present and will have their chance to say what they think of FM – and of Wayne Green, bless them.

It is likely that I will have a few words to say and that any lagging doubts as to why I am considered controversial will be settled once and for all. The fact is that I believe that a straight line is the shortest distance between two points, even if it bisects an advertiser or an ARRL official.



Saroc will run January 4th through 7th this time, with most of Thursday

Birmingham AL 35210

First off, Ralph WB8DQT, has some suggestions to supplement the photographic techniques I mentioned in the August column. If your camera is one that utlizes an electric eye for controlling the shutter speed, a piece of black electrical tape over the eye will automatically give you time exposures. Then all you need do is hold the shutter down 8 seconds. Also, you don't necessarily need to remove the yellow filter on the cathode ray tube. If your pictures are too dark, use the camera's color film settings of approximately ASA 75. Be sure to mark your settings after getting them right, so you will save time (and film) in the future.

Taggart also suggests using the popular SCR motor speed control units that are now available from most large department stores, to control light intensities on those camera flood lights. Usually these plug right in, so it should be super-quick, and sure beats fumbling with the camera's settings.

I understand that Mike W6MXV is developing a programmable MOS Memory unit. Slow Scan transmission capabilities without the aid of a camera or tape recorder. Probably he

ARRL & FM

The League is showing an increased (if belated) interest in FM and was represented at the recent FM Symposium (hosted by 73) by W1ICP, who was most helpful with suggestions and ideas.

More on the symposium on page 281 . . .

AMSAT NEWS

Mike Frye WB8LBP
640 Dauville Dr.
Dayton OH 45429

OSCAR 6 launch date October 11.

From all the reports I have been receiving, A-O-C is progressing at a good rate. Launch preparations are progressing smoothly and to my knowledge the launch is on for late October.

I have been getting a good response from amateurs all over the country. Although many still seem unclear as to the exact uses of the satellite. The ten to two meter repeater will accept *any* form of transmission – this of course includes FM. However, the repeater operates most efficiently on CW, SSB, and AM respectively.

The estimated area that can be utilized through the satellite is easy to determine. Simply draw a circle from your location with a radius of 5000 miles. This should give you an idea of the countries you should be able to work.

A-O-C provides for DX every day. Information I have received from John Gregory W3ATE indicates that the satellite should be in the local area at 7, 9 and 11 a.m. and p.m. for about 25 minutes each duration. Length of the duration depends on your latitude. Twenty-five minutes is a good estimate for the latitude through Pennsylvania, Ohio, etc. The greater your latitude the longer the duration of the signal. If you were to live on the upper edges of Canada you would receive almost three hours of continuous use twice a day! *WB8LBP*

50 MHz BAND

Biff Turner WAØABI
Five Chestnut Court
St. Peters MO 63376

The band continued opening through early September, while not as frequently as earlier, it provided many excellent contacts. Conditions and activity during the ARRL contest were good-to-excellent for this time of year. Groundwave during the first two weeks of September was exceptionally good with contacts to 500 miles commonplace. TV signals were noted on all (VHF) channels on a number of occasions. During the early morning hours of September 2, WTWO Indianapolis, was received for several hours with signals as strong as the local channel 2. Numerous calls on 6 brought no reply.

Six meters is in the midst of a period of rapid growth in the St. Louis area. In the past six weeks WAØRQH, KØYYV, KØRWV, KØWYN, WB9JGR and K9YNN have become active for the first time on SSB; in addition WØWEQ, KØRMF and WØAJQ have returned after periods of inactivity

Terry WA4WDU, and John WB2VNI/5, are increasingly active from Memphis. WB4HEL/4, also from Tennessee, was heard almost constantly during the contest. WA5SJM, Marked Tree, Arkansas, is active on a daily basis on CW and SSB.

The annual conference of the Central States VHF Society was an interesting 3 days for the serious VHF crowd. Items of special interest to the 6 meter group were tape recordings of the first (CW) moonbounce contact between K5WVX and WA5HNK, tapes and slides from the VP5RS DXpedition presented by WW4GDS and WB4BND, and Dr. D. E. Olson of the University of Minnesota Physics Department presented a most interesting talk on the subject of magnetic storms. On the lighter side, W1HDQ, "Mr. VHF," recounted the virtues of 2 meter FM to what is without a doubt the largest gathering of knowledgeable VHF/UHF people anywhere. Among the 6 meter group in attendance were K8LEE, WA8PEB, WAØVJF, WBØBBC, WØGNS, KØLCB, KØTLM, WAØTXV, WA7FPO, W7EN, VE4MA, W5WAX and WØPEP.

WB4WNV asks some questions on behalf of four hams in his area, the answers to which might be helpful to others. It is easy to get in the habit of assuming all readers have 6 meter experience. Lowell's letter reminds me

W2NSD/1 continued

talk from one end of Circus-Circus to the other – get rides from one casino to another via cruising FM mobiles – the 4th spent meeting and setting up the exhibits. On Friday everything gets going bright and early as the last arrivals drive in from California – the exhibits are going all day – the FM Symposium will be going strong – and that evening a couple of thousand amateurs spread out all over Las Vegas, handy-talkies in hand, to see what mischief they can manage. They make a few rolls at the tables – hit the slots – and end up in the Standard FM Hospitality room to lie a lot.

Things are in high gear on Saturday too until the big prizes are given away in the late afternoon. After a short rest everyone is ready to get out to see the extravaganzas up and down the strip. If you monitor 94 you will hear something akin to CB channel 10. You may hear one chap asking another to pass the salt to the other end of his table – or, after a few drinks, you may hear almost anything. And what about the chap, who had better remain nameless, who put his hand unit down so it stuck on and broadcast every intimate detail of a most interesting contact? I understand tapes are available.

Work Saroc into your schedule this time – it'll be fun.

My plans are to stop up at Aspen on the way back for a few days on the skis. Anyone else interested?

. . . *Wayne*

SSTV continued

will make this available on P.C. boards, like the W6MXV monitor. Incidentally if you have a chance to see this monitor or the J & R Electronics MXV 100 (similar circuitry with some additional goodies), don't pass it up. This one really comes on strong and the pictures are great. Watch for my upcoming reports on these units in 73 for full technical details.

Asia is again being represented on Slow Scan by a few 4X4's. I really can't describe the thrill of seeing those boys identifying with Israeli writing on the screen, but it surpasses even the best DX audio QSO's. Watch for them on 14.230 kHz around 0000 GMT. Also, you might watch for ON4CZ, VP2ME or 8R1W, some of the newer hams to join the SSTV ranks. I understand also that the U.S.S. Hope is on SSTV, but I don't know their call. And watch those VK3's on SSTV. They recently formed the Eastern Mountain Radio Club (for SSTV) and are really coming on strong. You will probably be hearing quite a bit about the special P26 Phosphor they have come up with especially for SSTV use. This is a real beauty and can be viewed in any light; even daylight. I understand they can re-gun and re-phosphor (no splitting – they do both or no deal) any cathode ray tube with a "soft envelope." They determine if a crt is "soft" envelope by filing (carefully) a

Silver Spring MD 20910

Connecting a rig up to the ac line overseas can pose problems. In fact, connecting anything American causes a potential problem, be it a rig, an electronic flash gun, or anything requiring a recharge of internal batteries.

Just because you have a plug that fits the wall socket does not mean that you can connect the plug to the line cord and plug it in. It is first necessary to determine the value of the local line voltage, as described last time. Then knowing the requirements of the rig, something can be arranged. If the rig does not have multi-voltage line input facilities (like an FT 101) then a transformer will be needed.

If you wish to buy one, ac transformers for dropping 220 volts down to 110 volts can be obtained at Lafayette and other places, suitable for use at powers of up to one and a half kilowatts, more than enough to run any rig barefoot. These transformers can be home-brewed by connecting plate transformers up in reverse, that is, by plugging the secondary into the ac line and the primary into the rig. Turns can be added or removed from the secondary to make almost any hefty ex-TV transformer suitable. The only thing to watch is that overseas, power line frequences are usually 50 Hz, which means that the transformers used over there require more core area than if used stateside. If the transformer is not used under full load conditions that requirement should not bother the travelling ham.

When winding or unwinding turns, the transformer can be tested by running it in reverse. That is, by plugging the primary into the ac line and measuring the voltage at the secondary. When fiddling with the turns, aim at a value around 230 volts.

When you are satisfied with the voltage ratio, tidy up the loose windings. Use lots of masking tape or similar stuff. Next connect a female ac line connector to the 110 volt side. A heavy duty drugstore ac adaptor is just the thing. Leave as much cord in the line as possible. Then connect some cord to the 230 volt side and leave the ends bare. When overseas, obtain a local line connector. A connector can usually be borrowed from a nearby appliance – the trusty screwdriver strikes again!

If you are not taking an antenna with you, or are unable to get one up, a unit such as a Johnson Matchbox and an swr bridge is a must. With those devices you can load up bedsprings, window frames or long thin wires. You may not work any exotic DX, but you will put out a signal and work something on the HF bands. Being an avid VHF'er I recommend VHF for working the locals, but the HF bands have their place in enabling contact to be kept with home while in far-off lands.

14230	14040
21340	21040
28680	28040

that this is not the case. *Q. "Is the TVI problem as bad with SSB as it is with AM? It would seem not, due to the absence of a carrier."* A. The lack of carrier does little to reduce interference. SSB produces RF as you talk, giving the TV viewer the opportunity to watch between words and sentences. I have found they will seldom settle for a shared time status. Probably the greatest reason for TVI reduction is heterodyning rather than multiplying to the output frequency. This minimizes the change of oscillator harmonics falling in a TV channel. The average AM transmitter uses 8 MHz crystals multiplied by 6; if you were operating on 50.400, an 8.4 MHz crystal would be used. The seventh harmonic would fall in channel 2, the eighth in channel 4, etc. In a well-designed SSB rig the only harmonic you need normally worry about is the fourth of your output frequency which falls in one of the high VHF channels. This is not difficult to trap out if the need arises. The major TVI problem with SSB is fundamental overload. This may be cured in most cases by the installation of a GOOD high pass filter on the TUNER of the affected TV. Most manufacturers supply these free on request. By the way, don't believe the old wives' tale to the effect that you can't understand an SSB transmitter on a TV or Hi-Fi, nothing could be further from the truth! *Q. "What frequencies are commonly used in this part of the country?"* A. 50.110 MHz has become the calling frequency for most of the world, only in areas where this frequency is not assigned to the amateur service is activity greatly removed from 50.150 ± 50 kHz.

WAØABI

MARS

Harry Simpson A4SCF
P.O. Box 27015
Memphis TN 38127

Several months ago when this column was visualized, it was intended to be a sort of clearinghouse for MARS information – a column designed primarily to inform MARS members in one area of happenings elsewhere. Many telephone calls were made, many letters written and scores of personal friends were contacted, requesting information that would be of general interest to the entire MARS membership.

After the first effort appeared in the May, 1972 issue of *73* Magazine, it became apparent that most MARS members are already well informed, and that the column was of more interest and benefit to non-MARS members. That change in direction was all right with the author – since his feelings for the MARS program border on the apostolic! After more than twenty years as an active member of Third US Army MARS it could hardly be otherwise.

You see, in spite of propaganda from other sources, MARS is unique in that it exists solely as a result of the efforts of thousands of dedicated individuals. Reactionary and bureaucratic conditions are not allowed to exist – on the contrary, MARS is progressive and innovative! Whatever the field or interest MARS members are numbered among the leaders. Suggestions for the betterment of the program are welcomed, quickly evaluated and just as quickly placed into effect if worthwhile. No Board of Directors, No General Manager – just pleasant, efficient communications at its most enjoyable best!

Your response during the past six months has been, to say the least, terrific! Last month alone, over two hundred letters were answered. The writer has an aversion to form letters, feeling that those who took their time to write deserve nothing less than a personal answer; however, due to the massive influx of correspondence, the only solution was to mail a MARS brochure and trust that all questions were answered thusly.

A suggestion – if you would like to become involved in MARS and do not know any MARS members – attend your local ham club meeting and let it be known that you would like to become a member of MARS. It probably won't take more than a couple of minutes to make your first contact.

HOT GEAR

This gear was stolen on August 23, 1972: Swan 270B, Ser. No. M-395430, hand-held microphone for above, model No. 404, with groove filed in P.T.T. switch to lock in talk position. Contact Jeff Lackey W8HST, 7760 Willis Road, Ypsilanti, Mich. 48197.

Roger WA1NVC has had his HR-2A lifted from his car in Somerville MA. If you know anything about the whereabouts of Roger's rig (Ser. No. 04-07152) please let him know. Most ham gear looks like CB equipment to thieves; and there is a big market for CB gear. Please take the proper precautions with your rig.

On the other hand, if you reside in an isolated area with no ham club, you are just as important and welcome. In such a case, if you live in the East write MARS Director First Army, Ft. George Meade, MD; in the Southeast write MARS Director Third Army, Ft. McPherson, GA; in the Mid- and Southwest write MARS Director Fifth Army, Ft. Sam Houston TX; in the West and Northwest write MARS Director Sixth Army, Presidio, San Francisco, CA. They will gladly furnish information concerning your entry into the MARS program.

Sincere thanks to all who have helped this effort with information and/or moral support – to Wayne Green for the soapbox, to Col. Woodside in Washington, Jim Cooper in New Jersey, Hal Mulkey in Atlanta, "Andy" Anderson in Rome, "Doc" Klotz in Memphis, Bill and Margaret Pearre in Houston, Russ and Lucille Peck in Oregon and Maurie Schmitz in Hollywood – to name a few.

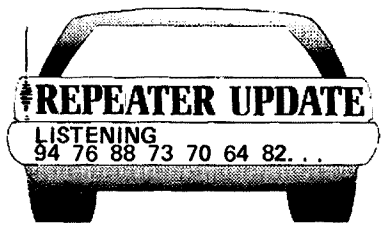
If even one amateur has found his niche – a new and exciting way of life in the MARS program, then these hours shall not have been spent in vain!

A4SCF

Microwaves

Jim Weir WB6BHI
Box 23233
San Diego CA 92123

Nice letter and enclosure from Bill Turner (WAØABI). It seems Bill works in the Gallium Arsenide facility (that's the Gunn and Impatt diode material – GaAs) of Monsanto Chemical in St. Louis, and found a few *hundred* surplus GaAs diodes in the microwave package. Unfortunately the diodes had been used in a destructive life test, and were 75% shorted and 25% open. Oh, well, Bill had good intentions of supplying all you microwave cats out there with free diodes. Sorry it didn't work out. How about some inputs from you other people in the industry.



An item in one of the trade magazines notes that the FCC has purchased a mobile van to study "crowding conditions" in the bands 25–512 MHz. A computer controlled spectrum analyzer will sample specific signals and note the time usage of each frequency in this band. Why no study of the microwave bands? Simply because there is no crowding in the bands above 1 GHz. For instance, above amateur "1" band (1215 MHz) there is more spectrum space in this band than in *all of the lower bands* combined. The same statement holds true for all higher bands. Each higher band contains more space (spectrum width) than all the bands below it combined.

An interesting sidelight of the above discussion for those of you interested in the "ultimate" antenna location for the dc bands; put your 20-acre rhombic for 160 meters, your 500 foot mast and 15 element beam for 80/10 meters, and all the other antennas you need for all bands through 2 meters up on the 5000 foot hill, and beam all signals on *all* bands (not just the amateur bands) through 150 MHz down to your house on amateur "s" band. Yes, you will have a full 150 MHz bandwidth from 2300–2450 MHz.

Or, for those of you interested in ATV, you could put 20 fast-scan TV signals with 4 MHz (broadcast quality) bandwidth in amateur "1" band with enough space left over to put all the amateur signals from 160 through 6 meters in simultaneously.

Let's hear from those of you who are using the amateur microwave bands – your fellow amateurs will benefit from your experience.

CALIFORNIA ACTS!

The repeater groups of Southern California gathered on September 9th for an FM symposium. Approximately one hundred attended the conference, representing over 40 repeaters. The result was an agreement (with but one nay) to adopt the 600 kHz plan.

The meeting was moderated by Skip Clark WB6TXX. It was co-hosted by the Edgewood ARS and the Pallisades ARC and the chairman was John Griggs W6KW.

The result of the scramble for standard channels at the end of the meeting was this:

01–61	WB6ZDI (PARC)
04–64	WB6WLV
07–67	WA6FLH
10–70	WA6TIC (RTTY)
13–73	W6IN, WB6RSK
16–76	WA6ZZR, WB6SLC, W6ZGC
19–79	K6SYU
22–82	W6FNO, WB6TSO, K6ZXZ
25–85	WA6ALV, WB6IWF
28–88	WA6SIN, K6QEH, WA6ZYN
31–91	WB6VQD
34–94	WB6GUA + simplex
37–97	WA6ZZE, WB6SZO
147.42–146.40	WA6TDD
147.60–00	WA6IRY
147.63–03	W6GY
147.66–06	W6IWY
147.69–09	WA6TWF
147.72–12	W6QFK, WB6VMV

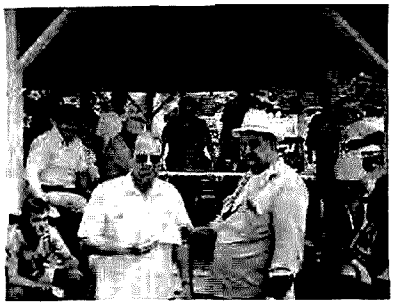
147.84–24	K6MYK
147.87–27	K6SIR, K6CPT
147.90–30	WA6PPS
147.93–33	WA6KSB
147.96–36	K6YDQ/K6VGP
147.99–39	WA6FLL (FAX)

FIRST BERMUDA REPEATER

The first two meter repeater on Bermuda is going on 34–94. This will be VP9BDA and, after getting checked out, will be set up on the lighthouse. It will cover the entire island. Remember to bring your handy-talkies when you go to Bermuda. Geting a license is simplicity – you get in touch with VP9EP, the Wireless Inspector (in the phone book) and he will get you set up. You'll get your own call/portable VP9. A visit to Bermuda is about 800% more fun when you get to meet and talk with the local amateurs – they are really great guys. 94-simplex fanatics may not be welcome.

NEW ENGLAND COORDINATOR 220 MHz BAND PLAN

The frequency coordinating team of K1KEC, K4GGI/1 and F2BO/W1 got together on the air the other evening to work out a new scheme for repeater occupation of the 220 MHz band in case the FCC is resistant to all requests to change their minds about cutting out the lower two MHz of the band.



The previously agreed upon 3 MHz split between repeater inputs and outputs will be changed to 1.6 MHz and the simplex channel will be 223.5 MHz.

Inputs	Outputs	Inputs	Outputs
224.98	223.38		
224.94	223.34	224.42	222.82
224.90	223.30	224.38	222.78
224.86	223.26	224.34	222.74
224.82	223.22	224.30	222.70
224.78	223.18	224.26	222.66
224.74	223.14	224.22	222.62
224.70	223.10	224.18	222.58
224.66	223.06	224.14	222.54
224.62	223.02	224.10	222.50
224.58	222.98	224.06	222.46
224.54	222.94	224.02	222.42
224.50	222.90	223.98	222.38

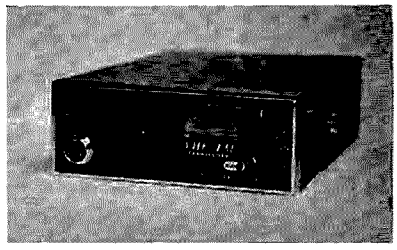
The frequencies 222.3 and below are reserved for the time being for present occupants of the band such as AM, sideband, CW, etc.

AKIRA KOBAYASI JA2AMD in his shack.

Look who was smiled upon by the Fates at the Six Meter Club of Chicago Picnic and Hamfest last August. Winning a year's subscription to 73 is Don K9TZZ on the left. Jack K9ZWU looks like he is a bit reluctant to let go of the prize . . . he must recognize the true value.

Some pictures taken at the Dayton Hamvention flea market. You missed it? Too bad!



INDIA ACTIVE ON SSTV

The first U.S. contact for VU25KV on slow scan was W6KZL. Glen is right in there pitching – and was the only six to make it to Navassa. He also makes a speciality of working as many countries from his car as possible and is now up to 251 – probably the mobile record.

KH6HJF has been putting his slow scan camera to a telescope. This is not only remarkable for views of the moon and the sun spots, but he has been able to transmit ½ in. letters clearly 83 ft from the camera!

NEW PRODUCTS

NEW TEMPO 220

While several of the manufacturers have been firming up their 220 MHz transceiver designs, Henry Radio has been spurring their Japanese supplier to provide a unit. It looks as if Henry will be the first one to be able to supply the 220 rigs in quantity.

Two samples of the New Tempo 220 were checked out at 73 and run through their paces. We must say congratulations to Ted Henry for getting these designed, manufactured and imported.

The rig is similar to the two meter FM rigs, but is deluxe all the way. It has all sorts of nice features. The twelve position channel switch is back lighted so you can easily see the numbers in the car at night – and the numbers are big enough for middle-aged hams to read without getting out their glasses. The power on-off switch is separate so you don't louse up either your volume or squelch settings every time you turn the rig off. The hi-lo power switch will no doubt stay in the 10 watt high power position when the rig is used in the car or at home, but the 3 watt position may be just what you want if you add a little nicad battery pack to this for shoulder use. The low battery drain makes it a natural for this – only 150 mA on standby and 250 mA on receive. It draws 2.8 amps on high power transmit

The receiver has plenty of poop (2 watts) to drive your car speaker – and there is a jack on the back of the rig to plug in the external speaker (this mutes the built in speaker).

This may be the first FM rig to have an S-meter which also doubles as a deviation meter! There is a switch to provide this function. On transmit the meter shows power output. The final is protected in case you forget to put on the antenna – or it happens to short out.

Both the transmit crystals and the receive crystals have warping capacitors. Less deluxe rigs save the cost of those receive capacitors. The warping

NEW PRODUCTS

100 WATTS SOLID STATE LINEAR!

It looks like solid state has finally hurdled the last barrier toward its conquest of the vacuum tube. TRW has announced that it is manufacturing a new line of RF power transistors designed for HF linear applications. Designated PT5740, PT5741 and PT5742, they will deliver 15, 30 and 60 watts output respectively when powered by a 12 volt source. They are brutes! In typical linear installations they will withstand a wide range of bias and temperature conditions. They are impervious to load variations as extreme as an open line or a complete short. Compromising protection and compensating circuitry is not required in most cases because of the unique TRW design. Intermodulation distortion products are claimed to be better than −30 dB and collector efficiency averages about 45% in SSB service.

True portability is here. No more big tubes, transformers or separate HV supplies for fixed and mobile operation. From now on the output stage

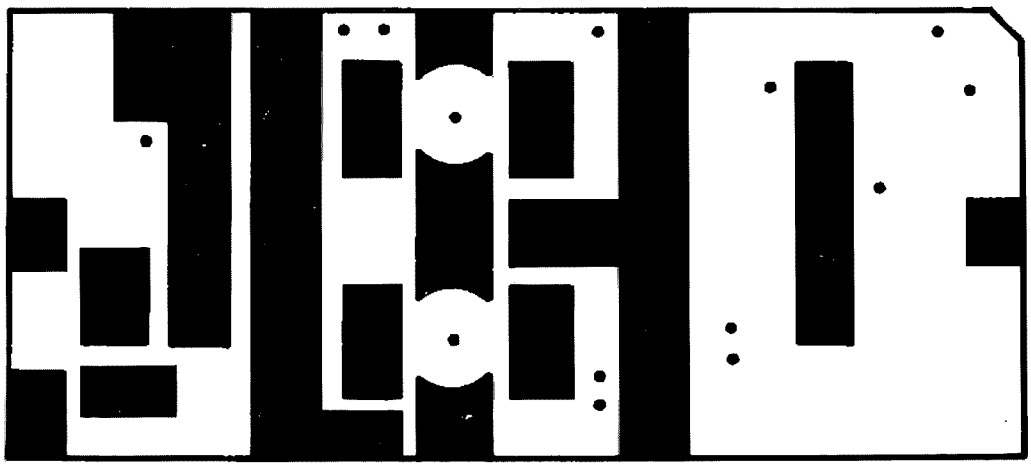
can be as compact as the rest of an SSB rig. Take a look at Fig. 1 and see how simple it is to get 15 watts SSB out of a transistor. With careful placement everything would probably take up less space than an average filament transformer.

25 Watt Amplifier

Figure 2 is a 25 watt amplifier using two PT5740's push-pull class AB. It will operate anywhere in the HF spectrum from 1.5 to 30 MHz without the need for bandswitching. Broadband switching gets pretty complicated when matching low impedances and a broadband arrangement simplifies things considerably. It will amplify anything fed into it, so a clean driving signal is a must. Harmonic suppression also suffers because of the non-resonant output. This is not too much of a bother because the even order harmonics are cancelled fairly well by the push-pull configuration. The odd order harmonics need not be troublesome if care is taken to make sure that the antenna system is Hi-Q and resonant. Or use a filter.

The transformers are interesting and they deserve a bit of discussion. The center tapped winding on T1 and T3 consist of two pieces of .190" brass tubing mounted between two PC board end plates. On one end plate the tubing is soldered together for the center tap. The other winding consists of a single wire wound through both tubes. The tube length for T1 is .80"

Details of transformer T1.



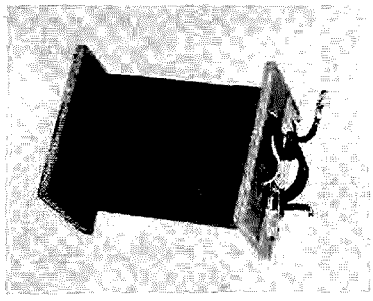


Fig. 3. Full size P.C. board for 25 watt amplifier.

T2 and T3, T2 is at the top.

and the wire winding is 4 turns No. 20 enameled. The tubes for T3 are 1.375" long and the wire winding is 3 turns No. 20 enameled. Large ferrite beads are slipped over the length of each brass tube before final assembly. T2 is mounted between the same end plates as T3 but consists of a twisted pair of No. 18 enameled wire run through both stacks of ferrite beads once (no tubing used). The photographs give details on the transformer construction.

This amplifier is perfect for an ultra-compact low power portable transceiver. With intelligent use of IC's and miniature components, it should be possible to build an all-band SSB rig about the size of the FM rigs currently on the market. A high-low power switch could be easily incorporated to make battery operation possible when no sizable amount of power is near.

100 Watt Amplifier

While a 100 watt amplifier could be constructed using only two of the higher power PT5742's, difficulty arises in trying to achieve the ex-

capacitors are very easy to get to, by the way. We say that in memory of an earlier rig or two where you had one hell of a time getting your crystals on channel.

The front panel is right up to date — black with green back lighting on the channel switch and meter. There is a little light that comes on when the squelch operates and we suspect that not a few amateurs will be using this for an emergency carrier operated relay. This rig looks as if it could be converted into a repeater very easily. The modules are all separate and relatively well shielded from each other.

We set one unit up on top of nearby 73 mountain and drove around with the other in the Rover, with a trunk mount Hustler 220 antenna (5/8 wave, of course). Frankly we couldn't see much difference in the coverage between the 220 rig and a ten watt 146 MHz rig. They both held up about the same and started falling off about the same. There seemed to be a few more hot spots where the 220 rig would peak up than on 146 once we were in a shadow area, but the difference wasn't remarkable.

The price is not firm on this new rig yet, but it is expected to run under $350. It would make a fantastic package at that price.

100 Watt solid state linear amplifier

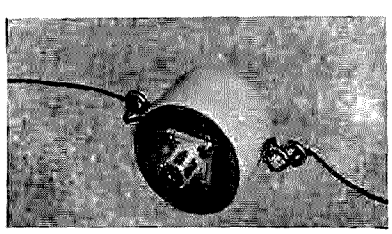
tremely low load impedance they require over the full range of 1.5 to 30 MHz. Thus they are more suited to limited bandwidth applications. The four PT5741's used here require a slightly higher load impedance than the PT5742's which makes broadbanding the circuit a bit easier. The 100 watt amplifier in Fig. 5 is essentially two 50 watt push-pull amplifiers that are fed in phase with each other through T1. Each output is combined in T8 and 100 watts overall is fed into the antenna. Any amplitude or phase unbalance is absorbed by R6 and R7.

This amplifier is designed to be driven by the 25 watt amplifier running class A. A slight bias adjustment will do this and the power falls to 5 clean watts which is the proper amount to drive the 100 watt amplifier to full output.

These two amplifiers are perfect for an all-band all solid state rig. They could both be incorporated into a small transceiver, or the higher power amplifier could be left forever in the trunk of your car to be powered by the miniature 25 watt rig that you store away in the glove compartment.

The two PT5740's and 30 ferrite beads needed to construct the 25 watt amplifier are available for $36.00 as Kit #PKT 3104 and the four PT5741's and 84 ferrite beads for the 100 watt amplifier are available for $112.00 as Kit #PKT 3103, from *Ham Radio Center, 8342 Olive Blvd., St. Louis MO 63132.*

MARK XII REGULATED SUPPLY



It probably has not totally escaped you that most of the equipment today is designed to run with a twelve volt supply. If you live in a car this is probably fine. If you want to use the gear at home then you have to come up with twelve volts.

The Mark XII people are not insensitive to your problems and desires. Their new 3A power supply has a voltage reulator built in which puts a lid on the voltage, holding it down to about 14 volts with no load. This is low enough so it should not cause any problems on low-current applications. An unregulated supply could pop your receiver or converter by swinging up to about 16 volts with a light load.

At $24.95 this is not a bad bargain to have around for running those gadgets which don't need much more than 3A maximum.

NEW HF BALUN

Palomar Engineers announces a new 1:1 Balun. It matches 50 or 75Ω coaxial cable to center-fed dipole or inverted Vee antennas. By preventing radiation from the coax it improves antenna radiation pattern, reduces noise on receive, and helps prevent TVI, BCI, and rf feedback within the station.

The Balun transformer is wound on a large ferrite toroid core and handles a full kilowatt power from 1.7 to 30 MHz. The transformer is enclosed in a white plastic housing and is completely encapsulated to prevent moisture from entering. All hardware is stainless steel.

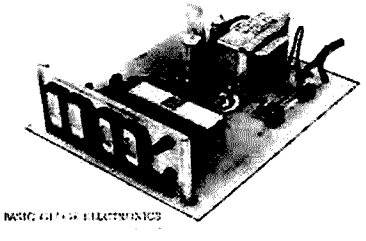
Eye bolts on the sides allow the Balun to replace the center insulator of the antenna and an eye bolt on top can be used to support the antenna. The Balun is a compact 2¼ in. diameter and 2 in. high. It is priced at $12.95 postpaid in U.S. and Canada (plus 5% tax in California). Write to *Palomar Engineers, Box 455, Escondido CA 92025* for a descriptive brochure.

FM ANTENNA MOUNT

A new mobile antenna mount that features fewer parts, simplified and quicker installation, lower silhouette and positive weather protection has just been introduced by Larsen Electronics. Designed to go into the usual ¾ in. hole, the mount is adaptable to any location on roof, fender, trunk, etc. Only three parts are involved and no special tools are required for installation.

The mount will accommodate either soldered or solderless fastening of coax according to the desires of the installer. A case hardened steel flange assures positive grip and ground connection to the vehicle. It will fit any antenna that requires a 5/16 by 24 thread and when used with the Larsen LM Antenna provides a low, low silhouette and thread to thread connection for greatest electrical efficiency. It also provides an installation that permits quick and easy removal of the antenna when the car goes through mechnical car washing facilities.

To install the Larsen mount one has only to attach the coax (step-by-step full scale illustrated instructions are included) and feed it to the equip-



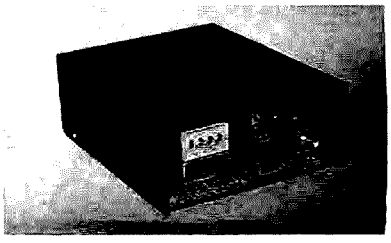
ment. The under part of the mount goes easily through the ¾ in. hole and a tough plastic fitting and weather-proofing "O" ring spins into place. With those three steps the mount is ready to receive the antenna. For more details, write to *Larsen Electronics, Inc., P.O. Box 1686, Vancouver WA 98663.*

PORTABLE FM ANTENNA

A new industrial type, continuously loaded VHF portable antenna, Model HM-5, has been added to Antenna Specialists high performance amateur line. Designed to withstand the rough handling that makes telescopics impractical, the new spring antenna is completely insulated and cannot accidentally be shorted out. It features a connector fitting that attaches directly to portable equipment with SO-239 connectors. Power rating is 25W with nominal input impedance of 50Ω. A companion model, HM-4, is identical except for a standard 5/16" – 32 threaded male mounting base. Both antennas are available from amateur distributors at a suggested ham net price of $5.95. For additional specifications, write to *Amateur Department, The Antenna Specialists Company, 12435 Euclid Avenue, Cleveland OH 44106.*

DIGITAL TIME

Ever since the first digital clocks came on the market, probably 30 years or so ago, we've been fascinated by them. And when the nixie readout clock became practical as a result of large scale ICs, we had to go that route, at any cost.



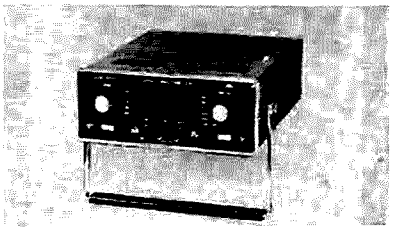
We started out with the Logiconcepts clock – a beauty. We use them in every part of the 73 offices. Those numbers lighting up are fun to watch, better than a navel. The only drawback was that the Logiclocks are over $100 and that limits their appeal a bit.

So along comes K-A Sales with a clock kit for $52.50! Grass did not grow under our feet – we sent for one. Beauty. With one enormous IC the clock converts the 60 hertz line into whatever it is the display numbers need to read out the hours and minutes – and, with a switch, the seconds. If that isn't enough it also has an alarm circuit built in, complete with a five minute snooze delay.

This clock is terrific for every ham shack. You can build it right into your control console and the alarm will help you remember those skeds – unless you are a lot better at remembering them than we are. We miss as many as we remember – or at least we did until K-A came along with this device.

If you get every accessory (most of them are just switches you probably already have) the whole bill only comes to about $75. Take a closer look at the K-A ad and see this gadget.

HIGH-RESOLUTION DIGITAL AUDIO SYNTHESIZER

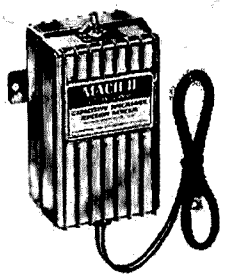


A new, precision frequency synthesizer with an output range of .1000 Hz to 9.999 MHz, and a single-unit price of $495, has been introduced by Syntronics Inc.

The unique solid-state instrument puts out a TTL-compatible square-wave signal having a frequency accuracy and stability of ± ppm from 0 to 50° C (With 1 ppm from 0–50° C available as an option). Frequency, to four signficant figures, is selected manually by means of front panel thumb wheels and a rotary switch which selects one of 8 available ranges. Decimal point poisition is automatically indicated by LED's on the front panel.

The Model SI-70 is believed to be the first high-accuracy instrument of its kind to carry a price comparable to that of many inherently less accurate audio oscillators and signal generators.

The new unit is extremely compact, measuring 8¾" x 3 1/8" x 6¾" and weighs approximately 5¼ lbs. Power requirements are 115V, 50–60 Hz @ 17 watts. Other options include: An output range extended down to .001 Hz; external BDC programming; external dc power unit; and an external 1 MHz-standard input. Write to *Syntronics, Inc., 169 Millham St., Marlboro MA 01752* for additional information.



NEW LEADER DIGITAL MULTIPLIER

The LDM-850, a digital readout ac/dc multimeter that measures voltage, current and resistance in 25 ranges, is now being offered by *Leader Instruments Corp., Long Island City NY 11101.* It offers a dual slope operating mode and has a maximum input voltage of 1,000V dc and 350V ac with 10MΩ input impedance. Sensitivity ranges from 100 μV to 1V with current from 0.2 mA to 1,000 mA, ac or dc.

The Model LDM-850 measures 10" x 7¾" x 3¼" and weighs 10 lbs; priced at $299.50.

CAPACITIVE DISCHARGE IGNITION SYSTEM

C-D SYSTEMS has announced a totally new CD ignition system, the MACH II COMPU-SPARK. The unit is designed to permit the length of the spark to be regulated with engine rpm. A very long spark at low rpm aids starting and idle smoothness. A built-in three-position switch permits C-D operation, standard ignition usage or "off" as an anti-theft feature.

The ignition system utilizes only silicon semi-conductor components for reliable operation under extreme temperature conditions. The unit will operate with any 12-volt negative ground system. It carries a no time limit free repair or replacement guarantee and costs $49.95. A free brochure is available from *C-D SYSTEMS, P.O. Box 484, Berkeley CA 94701.*

destroyed the micas in the higher power version. Figure 5 is the photo of the model being described. As usual, the largest single component is the heatsink. The one shown is minimum in size for the rating. Since the heatsink could be secured to the case of the equipment, additional cooling would be available. Figure 6 is the four-in-series string which delivers 200W CW output. Figure 7 is the photo and, of course, is the experimental

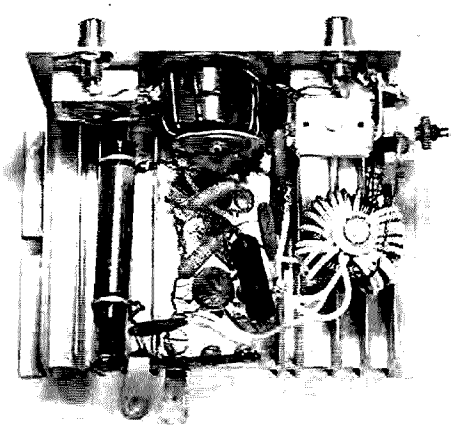


Fig. 5. 75W amplifier. Note heatsink size.

version. In both models the input circuits use a toroid made of ferrite cores by Amidon. For best efficiency, the driver stage would have the link secondaries wound over the primary; eliminating capacitor and toroid. A 50Ω output from the driver made development much simpler. Power measurements were made using a Bird wattmeter and dummy load. The driver was adjusted to deliver a maximum of 5W at 7.1 MHz. Driver turns ratio to primary was 5:1, but was not critical. Multicolored solid conductors proved to save time when wiring to the bases. All windings were the same in number of turns and polarities of phasing.

When the first model was made, all driving circuits to the base were series fed. About the only thing good about that connection was the self-oscillation. Simply by making the base shunt fed, the oscillation was stopped.

Here are some suggestions that may be of help in designing an amplifier that will operate as it should. I have seen as much as a 50% loss in power when the contacts were not as they should be.

1. All connections should be made with a mechanical contact, if possible with a copper strap. Then the joint should be soldered to prevent later corrosion.

2. Low resistance is a must in all circuits carrying rf, dc, or both. Don't take any chances with components when connecting to the heatsink or some other contact.

3. The conductor size should be large for best results. If a solenoid coil is used for the final, the wire size should be No. 9 or 10. If the toroid type is used, 3 sizes smaller will have the same rating when both windings are connected in multiple.

4. The number of turns is important in the tank coil if maximum output is desired. There is also the need of matching the load with the output. If a pair of ferrite toroids are used and wound as one core, the output will be reduced slightly but there will be space savings which may be important.

5. Each transistor should be balanced with the adjustment of the forward biasing resistor. When all are balanced for the same static current, the correct voltage division takes place and the dissipation should be reasonably uniform, as well as providing better linearity.

6. Do not be stingy with heatsinks! Operate the transistors cool if you want long transistor life. Blowers or fans can reduce the need for large heatsinks but there is the noise and other problems from the vibration and size of the cooler.

7. The use of silicon thermal lubricant is recommended, plus the secure mounting of the heatsink of the transistor to the heatsink.

8. The tuneup should be done with a variable rf source. Do not tune up at first with more than a few watts. The dc supply

SOLID STATE POWER

For many years there has been a need for increased rf power from transistor amplifiers to replace the output tubes in exciters. Cost, efficiency, distortion, power output, reliability, and stability from temperature changes have prevented the use of transistors in hybrid equipment.

The obvious advantages of this design will not be discussed in this article, as the purpose is to disclose a method of generating higher rf power from small transistors. Although the cost of transistors is greater than tubes, it is now possible to eliminate tubes and still be compatible with present costs. Two experimental designs are presented here. The first has two transistors in series and delivers 75W CW on 7.1 MHz. The second version is made with four in series and has a maximum output of 200W with approximately 5W drive. Using series strings of transistors has the advantages both in load impedance current ratings, and only a slight increase in collector voltage. TRW manufactures an HF isolated heatsink Model PT4526 which was used for all tests. A few other types were tried and operated as calculated. The other types did not have the isolated heatsink which presented a problem in thermal dissipation and mica isolation.

General Background

Three basic circuits will be discussed briefly. Figure 1 is the well-known grounded emitter. Since transistors operate efficiently in this mode, there is a tendency under certain conditions to go into self-oscillation. A second and more serious problem is in regard to the loading. Should excitation be

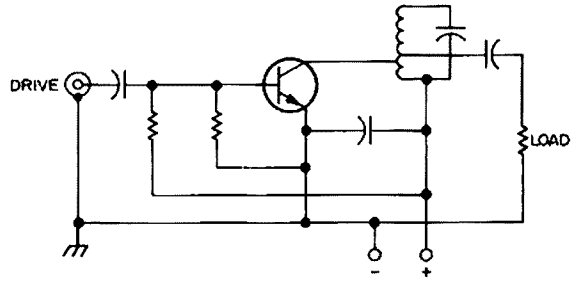

Fig. 1. Grounded emitter xstr amplifier.

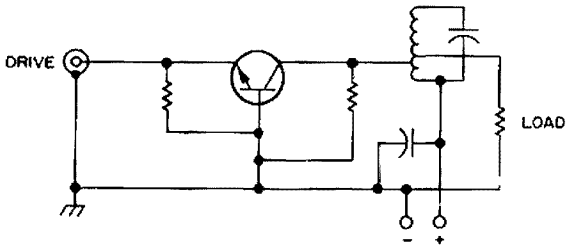

Fig. 2. Grounded base xstr amplifier.

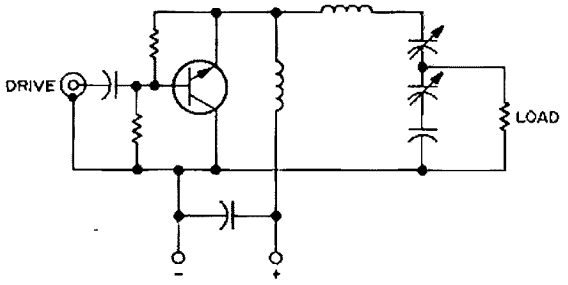

Fig. 3. Grounded collector. Notice detuning effect of the removal of the load.

applied without a load, the transistor in most cases will be destroyed due to the voltages developed in the high "Q" circuit.

Figure 2 can be compared to the grounded grid tube operation. This circuit is quite stable but requires more drive than the first circuit. For this reason, it was not used in the new design. Figure 3 is the grounded collector and has the following advantages: First, in the use of non-isolated heatsinks from the case, the collector is in good thermal conduction with the heatsink. Second, when the load is removed, the circuit is out of resonance and there is little danger of damage to the device with excitation applied. Third, much less driving power is required than the grounded base. Fourth, the circuit is quite stable in operation.

Description

The schematic diagram shown in Fig. 4 uses two TRW transistors in series. Toroids have been employed to save space. A smaller heatsink was also used, as there was less dissipation due to the reduced output. Small mica adjustable mica capacitors were used to contain the complete stage within the small heatsink. More output would have been obtained with larger components. The "L" net as shown has a different method of coupling than for the four transistor version. A link also could have been used, but this gave good flexibility in a small space. I might add that this is about the limit for compression micas. Increasing the power successfully

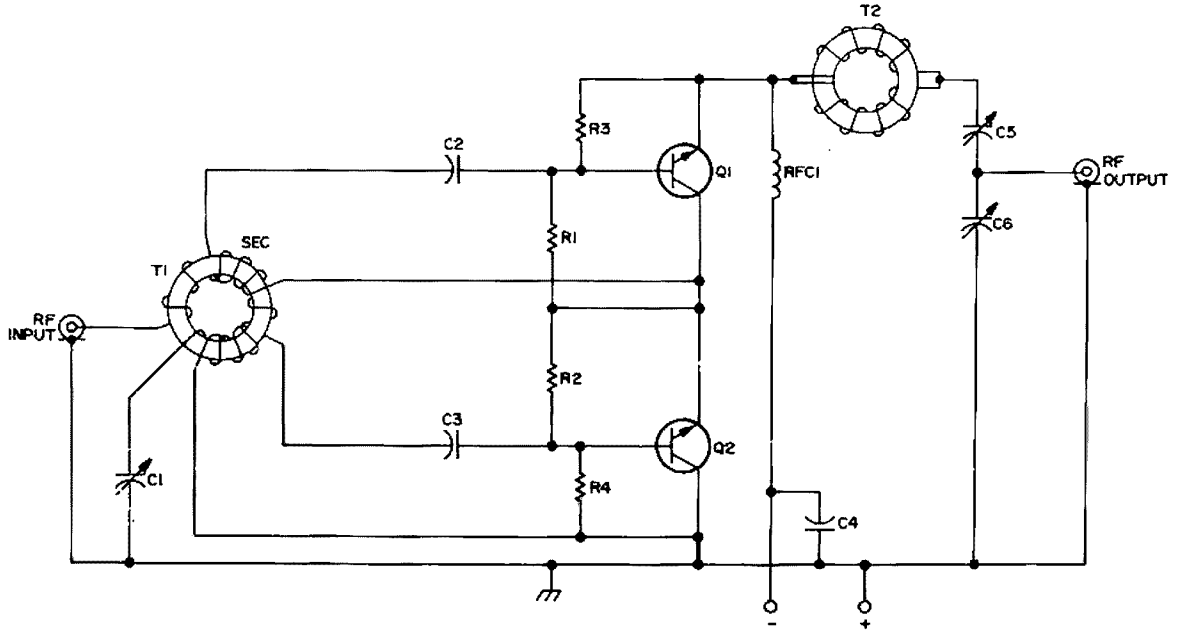

Fig. 4. 40m, 75W amplifier. T1: Amidon 15/16 in. toroid. Primary; 50T, No. 24. 2 secondaries; 10T, No. 24, solid insulated wire each. RFC — 3/8" diam. ferrite rod 50T No. 22 Formvar.

should be started at a few volts and raised to the maximum operating value only after the output is linear with the collector voltage. When an increase in dc voltage does not show much increase in output, reduce the collector voltage at once to a place where the linearity is restored. Operating above the linear point will only destroy the transistors. Increased loading usually permits the increase in collector voltage with a corresponding increase in power output. Always use a load to make the tests. After the amplifier is adjusted, both with the tank resonance and the drive resonance, then increase the drive. It should not be necessary to use above 5W of drive for high Beta transistors. Less efficient models will, of course, require more. Do not try to overdrive.

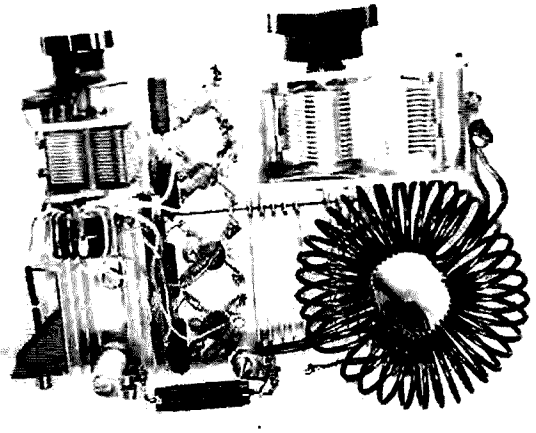

Fig. 7. Breadboard 200W amplifier.

Conclusion

The disclosure of this circuitry is done to aid those who wish to pursue the possibility of increasing the usefulness of solid-state amplifiers. No attempt was made to make a finished version, only to show one way to accomplish the production of higher rf output than has been previously possible. Although only tested briefly, the same excitation circuits worked on 75, as well as 14 MHz. The output was reduced in the final because of the improper LC ratios.

Wide ranges of operating frequencies should be possible when more time and energy can be expended in this direction. I have also considered the use of a push-pull "L" net for doubling the output. So far, not enough time has been available to pursue phase of development.

AN RTTY SELCAL WITH TTL LOGIC

The Selcal or automatic character recognizer has become a fairly popular accessory in stations equipped for RTTY operation. Particularly so in the case of people interested in automatic use of their printer while they are not actually in the station. With this equipment installed, a receiver may be left on continuously monitoring a frequency for RTTY signals, and the printer will start up and print a message only after the call letters of the station (or other start-up coded sequence) are received through the station terminal unit. A suitable turn off sequence to stop the printer is included.

The original description of a circuit of this type appeared in 1968.[1] It made use of the TRL logic available at that time. Since then, the entire line of TTL logic has become readily available to amateurs, and in fact is now so low in price as to be more than competitive with the RTL used in the original Selcal design. The merits of TTL have been discussed at length; and the great number of special and medium scale integration circuits available makes it very attractive for projects such as the Selcal.

With the thought of updating the circuit somewhat, yet retaining the original logic idea, the circuit to be described was devised and tested. This article describes the logic diagram, timing chart and functioning of the circuit; and presents a basic TTL design for the character recognizer which can be expanded for other features as desired.[2,3]

The overall circuit diagram is shown in Fig. 1. A preliminary glance at this shows it to be somewhat less formidable than the diagram of the original unit. This is mainly due to the use of two SN 7496 5-bit shift register medium scale integrated circuits. These replace the shift register which had to be hand wired in the case of the RTL design, and take care too of the turn off sequence circuit. The decoding is identical to the original using JK flip-flops.

Input

The input circuit shown in Fig. 1 (Q1 and Q2) can accept information from a number of sources. Probably the best input is a regenerated RTTY signal from the terminal unit which switches from a positive voltage on space to a negative voltage on mark. This sort of signal is available with the floating loop type terminal units like the TTL/2 and ST-6 that are favored by serious enthusiasts. A system making use of the keyer transistor with an emitter resistor as used in the ST-3 and ST-4 demodulators followed by suitable transistor circuitry has been described.[4]

For use with older type terminal units, it is possible to connect the input of Fig. 1 to the audio voltage developed on the space filter coil of the demodulator. This connection is often brought out as one lead to be used on an oscilloscope display of the received signal. If this connection is used, it is important to make sure that there is sufficient isolation between the T U filter

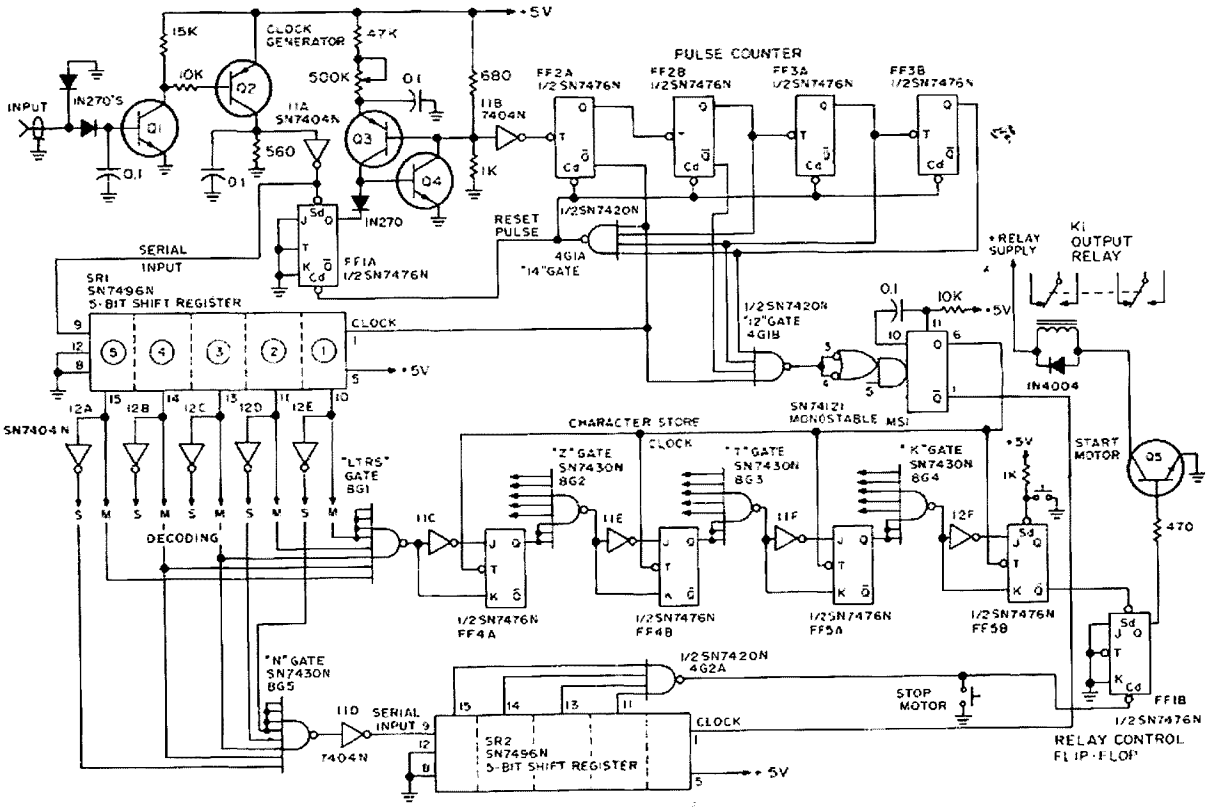

Fig. 1. TTL Selcal — logic diagram.

circuit and the Selcal input to prevent undue loading effects. Not much audio voltage is required to "trigger" the circuit. The diodes in the input circuit take care of rectifying the audio if used, or make correct usage of a digital type plus/minus signal if this is supplied.

For the condition of a continuous mark input, Q1 and Q2 are both off, and there is no voltage developed across the 560Ω resistor in the collector of Q2. This resistor acts to pull down the input of the SN7404 inverter, IIA, which is connected to the collector of Q2. Since its input is low, the output of this inverter is high for a mark condition. If the input to the Selcal goes positive (for a space signal) or audio voltage from the space filter appears at the input, Q1 and Q2 both get turned on; and the current through the Q2 collector resistor brings the inverter input up high, and so its output is then low for a space condition.

The base of Q1 and collector of Q2 are shown bypassed with 0.1 μF capacitors, and it is important that these values do not become too large so that the input switching circuit can accurately follow the reversals from mark to space of the RTTY signal and provides a good solid TTL level logic signal to the rest of the circuits.

Clock Generator Circuit

The clock circuit is familiar and has seen much use in electronic keyers and the like. It makes use of two transistors (Q3 and Q4)

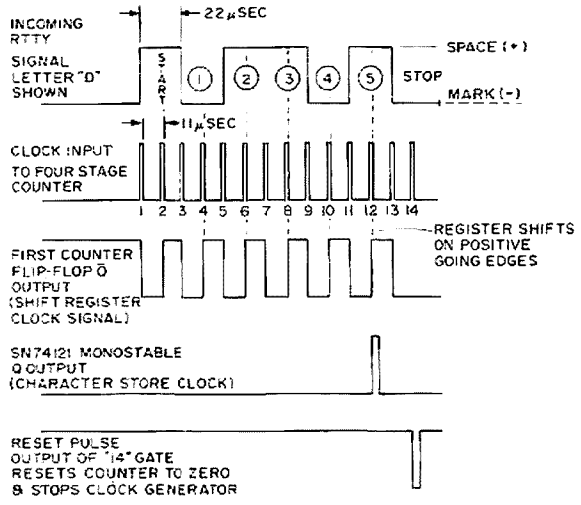

Fig. 2. TTL Selcal — waveform/timing diagram.

and one half of an XN7476 dual JK flip-flop which is used as a control element to start and stop the clock. When connected as in Fig. 1, Q3 and Q4 act much like a unijunction transistor, but with increased reliability in operation at lower supply voltages.

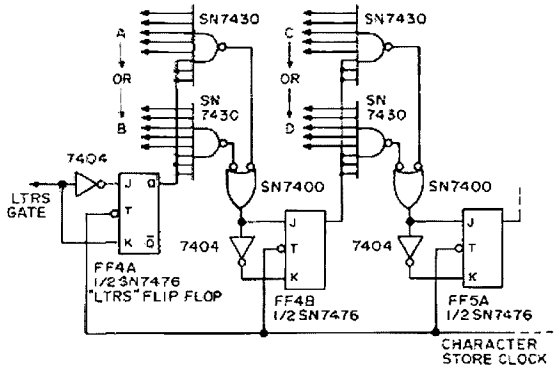

Fig. 3. Expanded decoding TTL Selcal.

As the 0.1 mfd capacitor at the emitter of Q3 charges up, a point is reached where Q3 starts to conduct and as this happens, Q4 also starts to turn on. Conduction in Q4 makes Q3 conduct even harder, so the result is a collapse of the capacitor charge in short order after which it starts to recharge, and the process repeats. The clock rate may be adjusted by varying the resistance in the charging circuit. A 500 K potentiometer is shown in Fig. 1.

The JK flip-flop during the mark condition is reset, and the Q output is then low. This clamps down the base of Q4 and stops the clock from running. As soon as a start pulse from an RTTY signal (space) comes along, this flip-flop gets set through its direct set input making the Q output go high. This allows the clock to start running. Note that as soon as the base of Q4 is not clamped to ground any longer, the clock immediately begins by generating a pulse since the capacitor at the emitter of Q3 is sitting there charged waiting for a space signal to come in. It is not necessary to go through a charge cycle on the capacitor which makes for more reliable synchronization of the clock and incoming RTTY signals.

The clock is stopped again when the control flip-flop receives a clear pulse. The operation of this portion of the circuit is covered during a discussion of the counter circuit and its associated decoding.

Pulse Counter

The pulse counter consists of four JK flip-flops which are series connected as a ripple counter. If not reset, they could provide a count of sixteen. The clock pulses from the collector of Q4 are thin negative going spikes, and are inverted to clean them up and provide a suitable thin positive pulse clock signal for the first flip-flop in the counter. The clock runs at twice the RTTY rate; 11 milliseconds for a 60 speed signal. By adjusting the clock frequency, other speeds can be accomodated.

So upon receiving a start pulse (space) from an incoming RTTY signal, the clock immediately begins running generating an input pulse to the counter forcing it to the count of one. The clock remains running and toggles the counter until the count of fourteen is reached, at which time it is reset to zero by the four input nand gate labeled "14" gate. This gate also feeds its output back to the clock control flip-flop and resets it stopping the clock after the count of 14.

There is another decoding gate connected to the counter circuit which detects the count of twelve on the counter. At this time, the output of the "12" gate goes low which triggers the SN74121 monostable I.C. This monostable is used to generate a one short pulse which is applied to the character recognition flip-flops to store a valid character if it is present in the register on the count of twelve.

The SN74121 is a versatile circuit. It can be triggered to generate a one shot output with either a positive going input on pin 5, or a negative going input on either pin 3 or 4. The negative going input is used here with pins 3 and 4 tied together. When the negative going input is used, the voltage on pin 5 must be at a high level (1 state) or else simply left unconnected as shown, which automatically places it at logic 1. The monostable also has suitable connections brought out for connection of external timing components to set the length of the pulse generated. The 10K resistor and 0.1 μF capacitor shown generate a pulse of suitable width for this application; slightly

less than a millisecond. Thinner pulses could be used to clock the character store flip-flops. With no external timing components, the monostable generates an extremely thin output pulse; something in the nanosecond area.

Shift Register and Character Recognition

The incoming RTTY signal reversals are fed into the character recognition shift register, SR1, and this register is clocked once every 22 milliseconds (for 60 speed) by the "not-Q" output of the first flip-flop in the pulse counter. The register shifts on a positive going edge as it has internal buffering on its flip-flops in order to present a single normalized load to the driving circuitry.

The SN7496 shift register has a serial input, and also inputs so that the individual flip-flops can be present to any desired state. The enable input for this preset function is pin 8 on the I.C. and is grounded in this application as the preset inputs (parallel load) are not used.

So, as an RTTY character start pulse comes in, the counter starts and clocks SR1 entering the various bits of the RTTY character in serial fashion. Inspection of the timing diagram, Fig. 2, shows that when the counter reaches the count of twelve, the start pulse has been shifted out the end of the register, and its five flip-flops contain the states corresponding to the RTTY character input. These states are a logic 1 for a mark bit, and a logic 0 for a space bit. At this point in the counting period, the character is in the register and ready to be inspected to see if it is one of the desired characters in the turn-on sequence.

Decoding

The Selcal as originally devised was used to look for and detect four consecutive RTTY characters, the first of which was the LTRS character sent after the area numeral in a typical amateur call sign. The logic diagram in Fig. 1 shows circuitry for a similar decoding sequence. However, if one's call letter suffix is not likely to occur in normal English text, the LTRS character may be omitted, using just the three letters of the station call. For two letter calls, the LTRS character probably should be included depending upon the make-up of the two letter suffix.

Omission of one or more letters for turn-on can eliminate a flip-flop in the character storage section if desired. Addition of the necessary circuits is worthwhile if maximum prevention of unwanted starts is desired, and the required circuits do not cost much.

Since only the true (Q-output) outputs are available on the I.C. shift register, a bank of inverters is used to provide a signal which will be at logic 1 level for a space entered in that flip-flop. The outputs before inversion are at logic 1 for a mark entry. This arrangement then provides a set of five lines, all of which will be at a high level if and only if the proper character is entered in the shift register.

The coincidental logic 1 on all five lines is detected using a series of 8-input nand gates (SN7430). The unused inputs on the gates are tied to one of the used inputs. When a desired character comes in, the output of the 8-input gate goes low since all its inputs are high for this character. Any other character input will provide at least one logic 0 input, making the output of the decoding gate high.

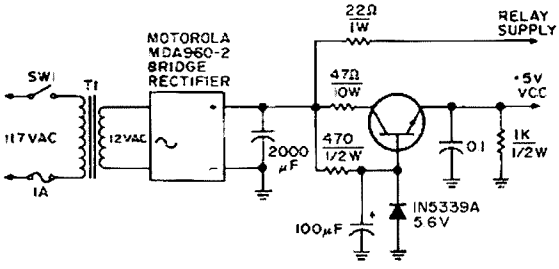

Fig. 4. TTL Selcal typical power supply.

Character Storage

The outputs of the 8-input character detection gates are applied to the inputs of four JK flip-flops, and these flip-flops are all clocked simultaneously by the pulse generated by the monostable, MS1, on count twelve in the counter. These flip-flops can only change to the true state (Q output at logic 1) if the J input is high. This state of affairs on the J and K inputs of the flip-flops

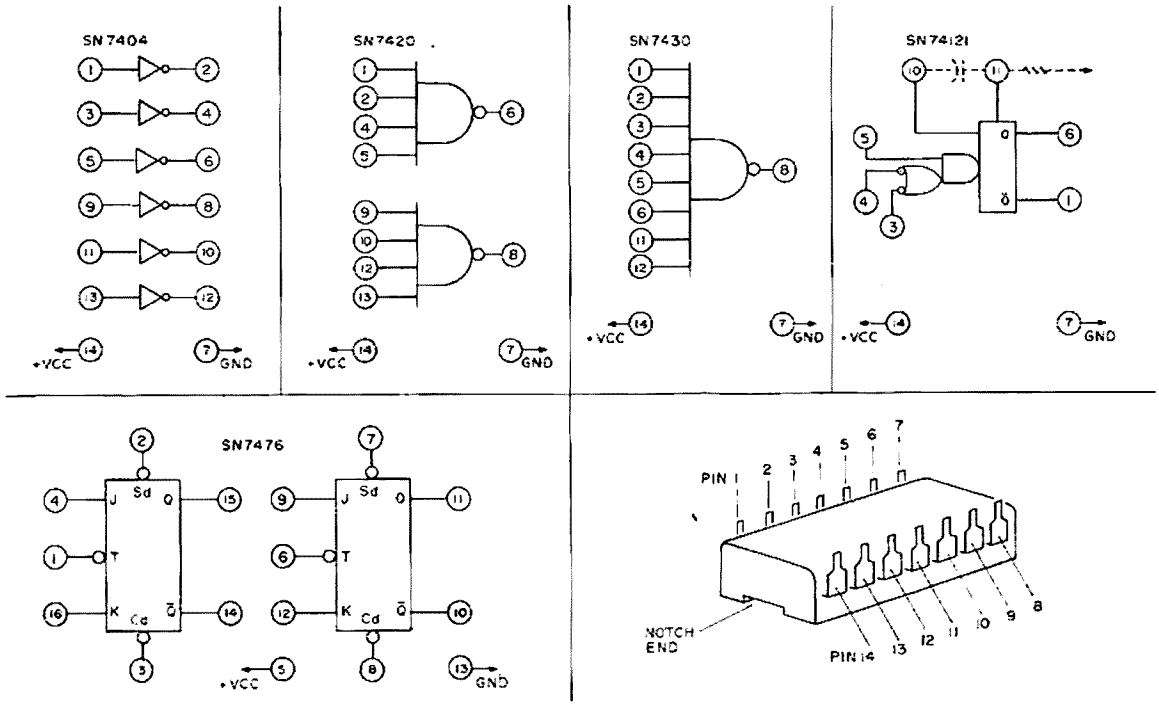

Fig. 5. TTL Selcal integrated circuit pin connections.

is present only when the desired character has been entered in SR1. In addition, the second, third and fourth flip-flops in the chain are fed with information containing the state of the previous flip-flop. If it is not at true level, the following flip-flop cannot change state. What this means is that for normal RTTY inputs containing text, the four flip-flops are continuously being reset by the clocks from MSI. However, for example, any time a LTRS character is received, the first flip-flop FF4A, will be set; and if the next letter is the appropriate one in the call letter sequence, the FF4A will be reset on the next character store clock, while the second flip-flop, FF4B, will then be set because the LTRS character has been received and FF4A was in the high state when the clock was applied. In this manner, only reception of the four desired letters consecutively can make the flip-flops FF4A, FF4B, FF5A and FF5B go set in "domino" fashion. Any false letter in the series stops this "cahin reaction."

When the last letter in the sequence has been properly recognized, the FF5B is set, its not-Q output applies a logic zero to the direct set input of FF1B and sets it which in turn drives on the relay through Q5. FF1B remains set even though other RTTY characters now come through the system, until it receives a turn-off pulse.

Four "N" Turn-off

Amateur users of the Selcal and other stunt box devices have adopted the standard commercial turn-off sequence of four "N" characters sent consecutively. In the TTL design for this Selcal, a different method of detecting four consecutive "Ns" is used, and makes use of another of the SN7496 5-bit shift registers. This further simplifies the circuit.

An 8-input nand gate, 8G5, is permanently wired up to detect the presence of an "N" character in the shift register, SR1. The "N" detection shift register, SR2, is clocked once each character by the inverse character store clock generated on count twelve. The not-Q output of the monostable provides this inverted clock signal.

If an "N" is present in the first shift register, the output of 8G5 will be low, and a logic 1 applied to the serial input of SR2 through the inverter ahead of it. When the clock comes along, the logic 1 is shifted into the register; and if a second "N" comes along, it too shifts a logic 1 into the register shifting the first 1 further along into the register. If four "N" characters come along,

the register will contain four logic 1 levels, and this situation activates the "N" decoding gate, 4G2A. Its output immediately goes low and this resets the relay control flip-flop at the direct reset input and opens the relay.

Hit Gate

Readers familiar with the original Selcal design will note that the TTL Selcal contains no hit gate. This feature was included in the original circuit to sense if a mark condition occurred part way into a start pulse. This situation would arise when the input was triggered by receiver noise and the like. If a "hit" was indicated, the pulse counter was reset and started over, so that continuous monitoring of receiver noise would not eventually provide the proper data inputs and give a false turn-on.

Since most of the more recent terminal units like the ST-3, ST-4 and ST-6 contain an autoprint section which requires a valid RTTY signal to be present for a short period of time before any loop output signals can be generated, the hit gate did not seem to be necessary, assuming that inputs for the Selcal were derived from the loop circuit in some fashion

However, if input information were to be taken from the space filter audio voltage as mentioned earlier, some unwanted turn-ons from receiver noise might be expected.

Power Supply

The power supply must handle a 5V dc for the logic circuits at a couple hundred milliamperes, plus a suitable dc voltage to operate the control relay. A typical supply for use with the 12V dc relay listed is shown in Fig. 4. The relay is a DPDT type and requires a coil current of about 80 mA for operation. Its contacts are rated at 10 amps ac and will handle the typical motor on a teleprinter. The unused set of contacts can be used for other control functions as desired. For example, they might light a light or activate a chime in a living area of the home to indicate that the printer was on.

Other Turn-on Sequences

Some Selcals were originally set up so that they would also turn on the printer upon receiving the combination LTRS*N*LTRS*N. This signal was used as an "All Call" sequence so that all the machines monitoring a given frequency using the Selcal could be turned on simultaneously by a transmitting station. Recognition of "QST" as an all call or the call letters of another active station on an autostart frequency are also popular.

One possible solution to the addition of a second set of turn-on letters is to decode only the mark and space bits which are common to each character. For some combinations of letters, this does not produce enough ambiguity among other possible letter combinations to give many false starts, and this system can be implemented without additional logic. In the simplest case, tying all the inputs of the 8-input decoding gates to logic one will give a turn-on after receiving any four valid RTTY characters and provides some protection from CW and continuous carriers over that normally provided by the autoprint and motor control circuits in the demodulator.

In most cases, it will be more suitable to slightly expand the decoding logic as shown in Fig. 3. This allows for two different turn-on combinations to be decoded if desired. However, it should be recognized that not only does this allow for these two sequences, but others as well as each stage of decoding is an "or" arrangement introducting a number of other possible combinations which will turn on the printer. The use of the LTRS character in the first place is of great benefit when this expanded code is used, but the combinations in each instance should be examined to see how many ordinary three letter words might be possible as valid turn-on codes. In most cases the first LTRS character pretty well eliminates false starts.

The addition of this logic requires an SN7400 quad two input nand gate as well as three more SN7430 eight input nand gates for decoding the three additional characters. Of course even further expansion would be possible using gates with more inputs.

Parts List

A list of parts for the major components is given. Also shown is a chart of I.C. pin connections for all but the SN7496 shift

register, whose pin connections are indicated on the main logic diagram, Fig. 1.

The integrated circuits can all be obtained from a number of sources that advertise in the amateur magazines. They should cost somewhat under $20 when obtained on the surplus market.

Substitution for the transistors shown is easily possible as any switching types will do in these circuits. 0.1 μF Sprague Orange Drop type capacitors are specified throughout to be consistent, but the only requirement for a stable capacitor of this type is in the clock circuit. Others can be disc ceramic or other bypass types if they are available.

If another dc supply voltage is available, it might be used to operate the relay for motor control. The newer solid state de-

TTL SELCAL PARTS LIST

Integrated Circuits
I1, I2 – SN7404 hex inverter

4G1, 4G2 – SN7420 dual four input nand gate

8G1, 8G2, 8G3, 8G4, 8G5 – eight input nand gate, SN7430

SR1, SR2 – five bit shift register, SN7496

FF1, FF2, FF3, FF4, FF5 – SN7476 dual JK flip-flop

MS1, SN74121 monostable multivibrator

Transistors
Q1, Q4 – 2N4124, NPN silicon
Q2, Q3 – 2N4126, PNP silicon
Q5 – relay driver transistor, 2N697 or equivalent

Capacitors

modulators mentioned already contain a motor control relay, and it might well be put to use in some way or other to be used in conjunction with the Selcal output signal. The method of control seems to be an individual thing which is best suited to the station at hand. Each one seems to be slightly different as are most RTTY installations overall.

Conclusion

In building this sort of circuit, be sure to include adequate bypassing on the 5 volt Vcc line around the circuit board. In addition a shielded enclosure for the circuits is a must to eliminate stray rf from getting in and upsetting circuit operation. Adequate filtering and bypassing of the signal lines going in and out helps here too. However, in most cases, a nearby transmitter will not be operating when the Selcal is required to do its job, unless of course, the station is transmitting on one band while monitoring another band at the same time. In such a case, rf elimination can best be achieved on a cut and add basis for the individual station layout.

A couple of Selcals using this circuit have been built by other amateurs using hand wiring techniques. These operated without difficulty. The author will be glad to try to answer individual queries regarding the circuit, construction techniques, etc. The considerable simplicity of this design makes for much easier wiring, even on a point to point basis, eliminating much of the chance for error in the final product.

AN INTEGRATED CIRCUIT TRF RECEIVER

An inexpensive Integrated Circuit has been available for some time which contains the complete gain, detection and agc functions required in 455 kHz AM i-f strips. Intended for use with ceramic filters and an outboard front-end converter, the LM372 is presently designed into the AM section of several commercial AM/FM high fidelity receivers, where it replaces the hand-assembled "i-f can" type strip formerly used.

The LM372 is, in reality, a much broader-band device than its 455 kHz applications would suggest. It has useful sensitivity throughout the AM broadcast band, the 160 and 80 meters bands, and even into the 40 meter band, when used to amplify pretuned AM signals directly from an antenna. Sensitivity, of course, is not as great as when used with the additional gain of a superheterodyne conversion stage, but is adequate for urban area broadcast reception, or local 160 and 80 meter net reception.

As may be seen in Fig. 1, there is considerable difference between the LM372 and a conventional i-f strip. The IC is basically a very high gain dc amplifier, with all its gain in one "lump," as opposed to the transformer coupled individual gain stages usually used. To keep the dc biasing constant, a negative feedback loop is used, with capacitor C3 making the loop effective for dc only; thus, ac (rf) gain is not reduced by the feedback system.

In conventional strips, agc is performed by shifting the dc biasing of the individual gain stages, effectively reducing their gain for strong input signals. Unfortunately, such bias shifting detunes the conventional interstage transformers. In the IC, however, the gain stages operate at maximum efficiency at all times; they are preceded by a separate agc attenuator stage, which can cut incoming signals by as much as 80 dB (10,000 to one).

Conventional diode-type AM detectors require dc biasing through the last i-f "can" in the strip, and are inherently nonlinear, causing distortion. The LM372 uses a more sophisticated detector, adapted from the op-amp type peak-following circuits used in analog computers. In this "active detector," the diode is inside an amplifier's feedback loop, which automatically biases the diode for linearity with small signals, actually gives voltage gain, rather than the loss of conventional detectors, and is directly, rather than transformer coupled, to the output of the gain stages. In Fig. 1, C5 is the detector smoothing capacitor, with the R4, C4 combination forming the agc loop.

The schematic of Fig. 2 illustrates in detail how the blocks of Fig. 1 operate. With no agc, Q2 is simply an emitter follower, with unity gain. Its output is coupled to the three gain stages, Q6, Q7 and Q8, whose output is directly coupled to the active detector, formed by Q11, Q12 and Q14. Dc feedback for the gain stages is performed through R8, C3, Q5, R6 and R7.

As input signals become stronger, the dc output level of the detector, at pin 6, rises

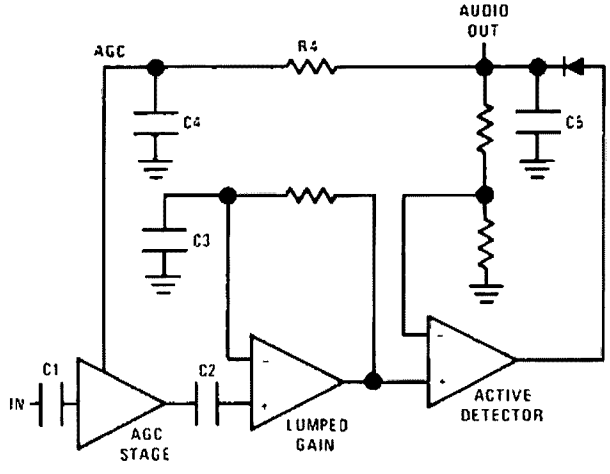

Fig. 1. LM372 block diagram.

R4 and C4 couple this voltage, with the audio component filtered out, to Q4 and Q3. Stronger signals begin to turn on Q3; since Q3 and Q2 form a differential pair, this tends to turn off Q2, giving an agc action that is both series (turning off Q2) and shunt (turning on the low-impedance emitter of Q3).

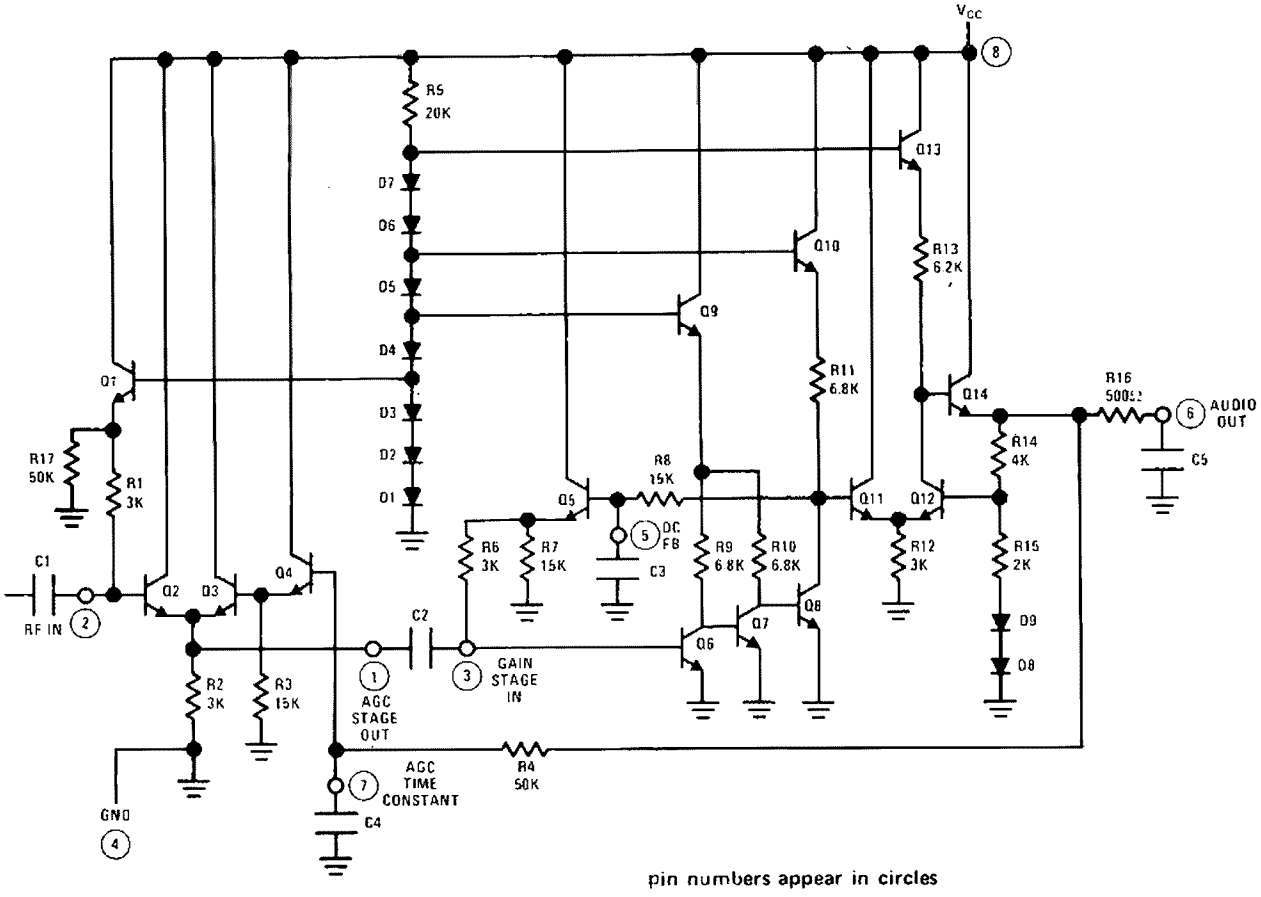
The string of diodes, D1–D7, and the various emitter followers attached to the string, act as separate power supply regulators for each stage of the LM372, which also eliminates the need for separate rf decoupling of each stage's supply line.

Broadcast AM TRF Receiver

As can be seen, there is no internal tuning in the LM372; it will amplify, detect, and agc all signals applied to its input. While in a superheterodyne receiver, it would be fed by an already bandpassed 455 kHz signal, the circuit of Fig. 3 allows it to roughly select any signal in the 550–1650 kHz band. The Tune Radio Frequency circuit has of course, poor selectivity, since it uses only a single tuned circuit which also acts as an antenna. Its selectivity is sufficient, however, to peak the desired station, which will then operate the agc so that overall gain is minimum required for that station. Thus, other stations will be far down on the single LC circuit's selectivity curve. More sophisticated designs might use multisection tuning ahead of the strip.

The prototype was constructed using very inexpensive imported "transistor radio" components. In fact, virtually any junked transistor radio will supply nearly all of the required external components for broadcast band use. A ferrite "loopstick" antenna, L1, resonates with a small, polyethylene dielectric tuning capactior. If operation is desired above the broadcast band, a smaller capacitor may be used, or the broadcast type may be connected in series with another capacitor, and then shunted across the coil, to lower the net capacitance.

The LM372 performs its gain function just as it would in an i-f application, but in this case directly drives a class A power amplifier. Since the dc voltage at pin 6 is relatively constant (varying from 2.1 to 2.4V



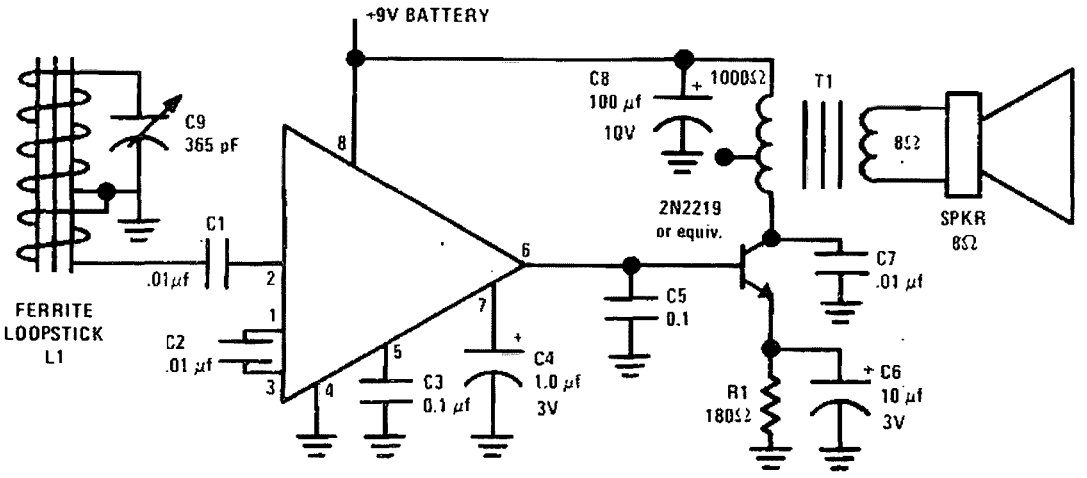


Fig. 2. LM372 schematic.

L1 – Ferrite Loopstick – Philmore FF15 (packaged as set of 3 sizes)
C9 – Sub-miniature variable capacitor – Philmore 1949G – 365 pF max.
T1 – Midget Audio Transformer, 1000Ω:8Ω – Archer 273-1380 (Radio Shack, Inc.)
SPKR – 2" PM Speaker, 8Ω, 0.1 watt – Philmore TS20

Fig. 3. TRF receiver using LM372.

as a function of agc), it is used to bias the class A stage directly, eliminating a number of extra components. C7 and C8 are needed to prevent regenerative audio oscillations with weak batteries. Care must be exercised in building the breadboarded circuit, as excessive lead length anywhere is likely to permit the very high gain strip to oscillate. A good technique is to use pin 4 on the TO5 can as a tie point for ground, and to connect all capacitors and other grounded leads to that pin with absolutely minimum lead lengths. Disc ceramics seem to have less stray inductance at these frequencies than the larger tubular types.

A volume control was not provided in the prototype, as volume was excellent with the small (2 in. diameter) speaker used, and agc was so effective that no perceptible difference in stations was heard in the broadcast band. A volume control which also reduces the class A stage's power drain at low levels can be achieved by inserting a pot between the emitter of the audio output transistor and R1. With the circuit shown, total drain from a 9V transistor type battery is 10 mA. of which only 1.9 mA is used in the LM372; the rest is needed for the audio amplifier.

Other Uses

Variations on the circuit of Fig. 3 might include padding of the C9 tuning capacitor, so that the loopstick could be used at 455 or 262.5 kHz as an i-f "signal sniffer" in receiver troubleshooting. If T1, C7, C6, R1, the speaker and audio output transistor are eliminated, the TRF receiver can be used, capacitively coupled, to drive high impedance headphones, or as a complete AM tuner in high fidelity applications. While selectivity is very broad, the high fidelity application will reveal that commercial AM stations really transmit more "tweeter material" than the average selective AM tuner will pass.

Another application would be to replace the loopstick with an equivalent shielded inductor, and to capacitively couple a broadcast-output VHF converter to the parallel tuned combination. Such a combination might be a simple answer to the monitoring of local VHF repeaters, where selectivity is unimportant.

Conclusion

The LM372 is a handy building block, in fixed i-f and TRF or variable i-f applications. A number of similar i-f "strips" are known to be under development; these will make the experimentally-inclined ham's life a lot more pleasant, and, along with other forthcoming communication-type IC's, should renew interest in the vanishing art of homebrewing.

THE MARK III ELECTRONIC KEYER

The Mark III electronic keyer (Fig. 1) is the end result of a joint cooperative effort by its designer Wes Hayward W7ZOI, and myself. Design improvements were worked out by W7ZOI in response to my requests for improvements in the original keyer circuit[1], for fixed station operation.

The Mark III keyer uses two additional transistors (Q4 and Q5), which replace one set of DPST relay contacts formerly required in the original circuit. The addition of three Fairchild 2N3564 NPN-type transistors used as zener diodes (in the base circuits of Q1, Q2, and Q5) replace two penlite batteries formerly required for reference voltage in the emitter circuitry. The addition of Q4 and Q5 permits the use of an economically-priced SPST relay, in place of the more expensive DPDT relay. The addition of the "space" and "mark" controls was my idea, since the manual adjustment of the off (space) and on (mark) duration times is a very desirable feature to have on *any* electronic keyer.

The keyer power supply was previously covered in the original article, "A Simple Electronic Key," which suggested voltage doubling a 6.3V filament winding to obtain 18V dc. I added an 18V zener (International Rectifier Z1116) connected across the output of the power supply as shown in Fig. 2. The 18V zener stabilizes the output voltage at a constant 18V dc. Voltage stabilization is *most* desirable, since it helps stabilize the keyer timing circuits.

Mark III Theory of Operation

For the benefit of those readers who do not possess the December 1965 issue of *QST*, the following explanation of Q1 through Q3 is briefly repeated. The theory of operation of Q4 and Q5 is added to cover the Mark III improvement.

During the "at rest" (paddle contacts open) condition, Q1 and Q2 are in saturation, Q3 is off, Q4 is saturated, and Q5 is off. See Fig. 1. Q1 is saturated because capacitor C1 in its base circuit is positively charged. Q1's collector current is maximum, and Q1 is said to be "saturated." Q2 is also saturated in a similar manner during this "at rest" condition. Q3 is off, because its base voltage is nearly zero volts (the same as the collector of Q2.) Q4 is saturated, because its base voltage is highly positive (the same as Q3's collector) and Q5 is off at this time, because its base voltage is nearly zero volts (the same as Q4's collector).

When the paddle "dit" contacts are closed, a negative pulse from Q1's collector is "steered" through diode CR1, and through the paddle "dit" contacts into the 5 μF "dit" storage capacitor C3. This negative pulse swings the base of Q2 negative, which turns Q2 off, and causes its collector voltage to rise to the supply voltage of 18V dc. The highly positive Q2 collector swings the base of Q3 highly positive, turning on Q3 (saturation). As Q3 goes into saturation, its collector current energizes the relay coil, which closes the relay contacts. Simultaneously, the base of Q4 drops to nearly zero volts (the same as Q3's collector), and Q4 is cut off. As Q4 turns off, its collector voltage rises to the highly positive supply value of +18V dc. Q4's high collector voltage swings the base of Q5 highly positive and Q5 goes into saturation. The emitter-collector current flow of Q5 causes a low resistance (short circuit) across the C1 "space" storage capacitor. This short circuit grounds the base of Q1, turning Q1 off. The collector voltage of Q1 rises immediately to the high positive value of the power supply voltage, but it does not upset the keyer sequence (even though the "dit" paddle contacts may still be closed at this time), because diode CR1 prevents passage of this positive high voltage.

The keyer circuitry continues in this "dit-mode" of operation, until the negative pulse (charge) on the "dit" storage capacitor (C3) has discharged through the "mark" and "speed" potentiometers to chassis ground. This, in effect, is the self-completion feature of the keyer. When C3 is discharged, the base of Q2 starts to rise toward a positive value. When Q2's base rises to approximately 0.7V, Q2 goes into saturation. This turns Q3 off, which opens the relay contacts and simultaneously swings Q4 into saturation. With Q4 saturated, Q5 turns off and removes the "short circuit" from the "space" capacitor C1. The *time* required for the voltage on C1 capacitor to rise to approximately 0.7V

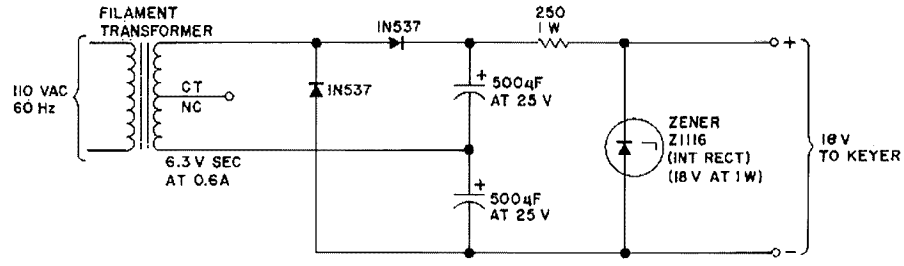

Fig. 2. 18 V power supply circuit.

creates the automatic space interval between dits. When this voltage reaches 0.7V dc, it swings Q1 into saturation. If the paddle is still being held in the "dit" position at this time, the entire dit sequence will be repeated. If the paddle had been returned to the neutral (at-rest) position prior to the saturation of Q4 and the turn-off of Q5, the keyer would only make one "dit".

When the paddle contacts are actuated to the "dah" position, the keyer operates in a similar manner as described for the dit sequence, except that the "dah" storage capacitor (C2) Diode CR2 (between C2 and C3 capacitors) steers the negative "dah" pulse into the "dit" capacitor C3, whenever a "dah" selection is made. The time required to discharge both storage capacitors should equal the normal "dah" duration time. For proper "dah" length, the combined capacity values of C2 and C3 should create a "dah" duration time which is 3 times longer than the "dit" time. However, because capacity values (as marked on capacitors) do not necessarily represent the actual capacity value, I recommend that these capacitors be selected by the "cut-and-try" method, until a satisfactory "dit" and "dah" length is obtained. (As a ball park figure, a continuous string of dits should cause the transmitter final plate current to hover at approximately 50% of the key-closed value. A continuous string of "dahs" should cause the plate current to hover at approximately 75% of the key-closed value.)

I added the 15K fixed resistor across the "speed" control to make the speed change more linear. The 1.2K fixed resistor at the top end of the "speed" control was added to limit the keyer top speed to approximately 45 wpm.

The "space" and "mark" potentiometer resistance values may require some juggling to cause the normal keying response to occur at the mid-range position of these controls. This juggling is necessary to compensate for the combined effects of relay return spring tension, relay contact spacing, relay armature mass, etc., which differs from relay to relay.

Construction Hints

The following construction hints are offered if the reader cares to duplicate my

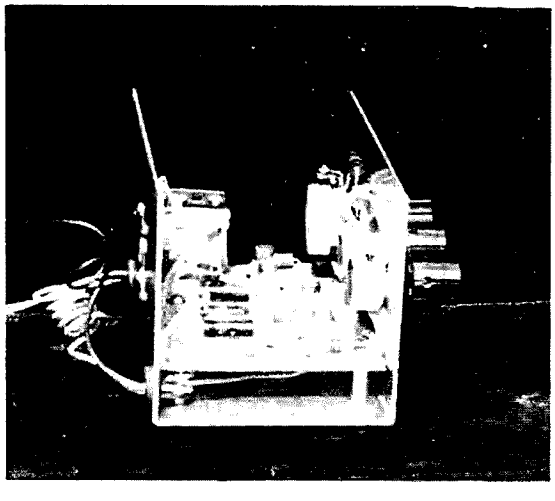

Fig. 3. Top view of keyer showing parts placement.

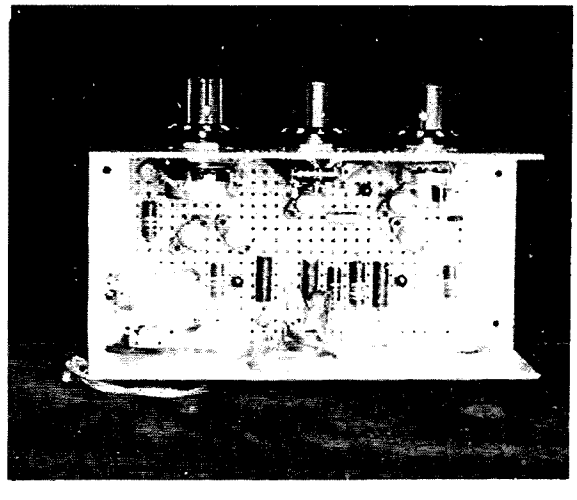

Fig. 4. Side view showing mounting spacers.

layout: Use a rectangular-shaped piece of phenolic pegboard as the base upon which to mount the circuit components (See Fig. 3). Use transistor sockets, so that transistors can be removed when troubleshooting or making continuity checks on the keyer circuitry.

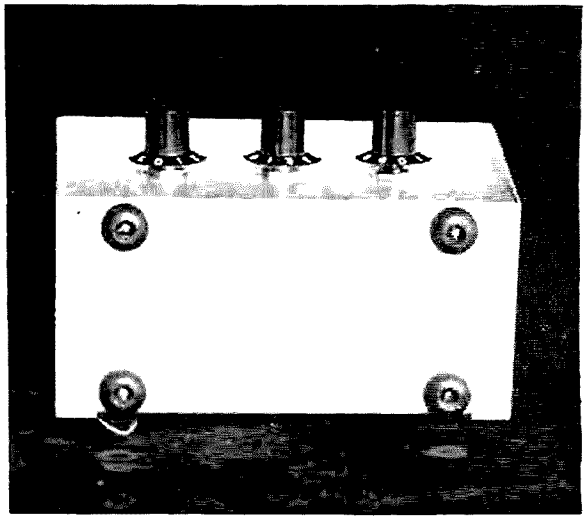

Fig. 5. Bottom details.

Support the phenolic pegboard at the corners with metal sleeve spacers (or equivalent) so that the pegboard is raised above the bottom surface of the metal cabinet. (See Fig. 4.) Use long machine screws to secure the phenolic pegboard to the metal cabinet. Pass these long screws upward through the rubber feet, the bottom of the cabinet, through the metal sleeve spacers, and through the corner holes in the phenolic pegboard. (See photos.) Secure long screws with lockwashers and nuts on topside of pegboard. Use a 1/8 in. thick, 2 in. square piece of plexiglas to insulate the 3-conductor jack sleeve connection from the hole in the backside of the keyer metal cabinet. Insert rubber grommets in the holes on the backside lower skirt of the metal cabinet to provide protection for transmitter key leads and power supply lead connections to keyer. When locating 3-conductor jack and "speed," "space," and "mark" potentiometers be sure to temporarily install the phenolic pegboard, so that the locations for the jack and potentiometers can be chosen in a manner which will not interfere with the components on the pegboard.

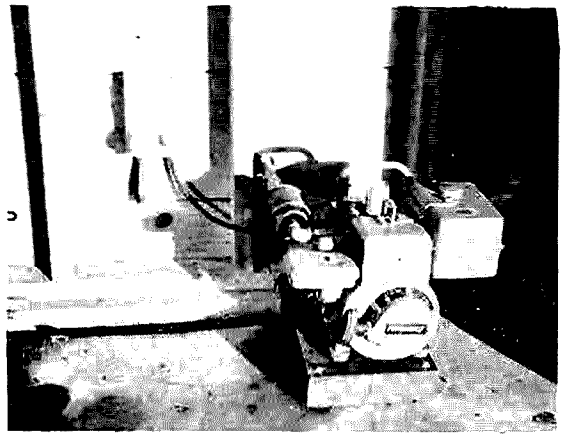
EMERGENCY POWER FOR THE HOME QTH



When the power goes off, do you reach for a candle or a power transfer switch? A small gasoline-powered alternator wired into the home electrical system can provide a lot of peace of mind by just being there. I live in a relatively remote area in the upper peninsula of Michigan. Power failures are not uncommon, and they can be a real inconvenience.

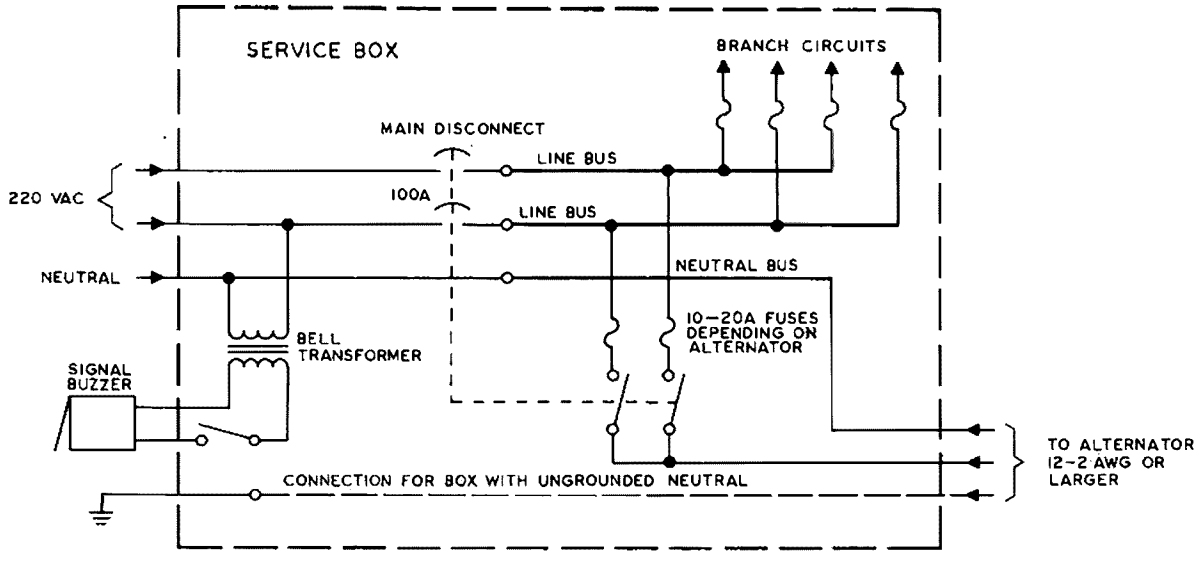
I installed an alternator large enough to operate the furnace, a few lights and the lower powered ham gear in the shack. The alternator was installed to be easily removable for field day or emergency service.

Installation

Nearly every installation will have at least slight variations. Also, wiring code requirements are not uniform nation wide. Some areas permit solderless connectors in service boxes, as would be used for connecting the alternator input line to the wiring harness. Other areas require all connections in service boxes to be made at rigidly mounted terminal blocks. Some may require the large commercial power transfer box regardless of the size of the alternator. If in doubt, contact the power company or public utility commission. It is beyond the scope of this article to go into the details of all types of installations or the automatic and semi-automatic power transfers.

There are two basic precautions to observe when installing an alternator. First, most power companies require a reasonably fail-safe switching system for power transfer so power from the alternator cannot be fed to the power lines. The interconnect also prevents the power from being accidently fed to the alternator with disasterous results. The ideal switch is the commercial power transfer switch. These switches are required for the larger 220 volt alternators. An acceptable, and considerably more

Alternator mounted in garage.



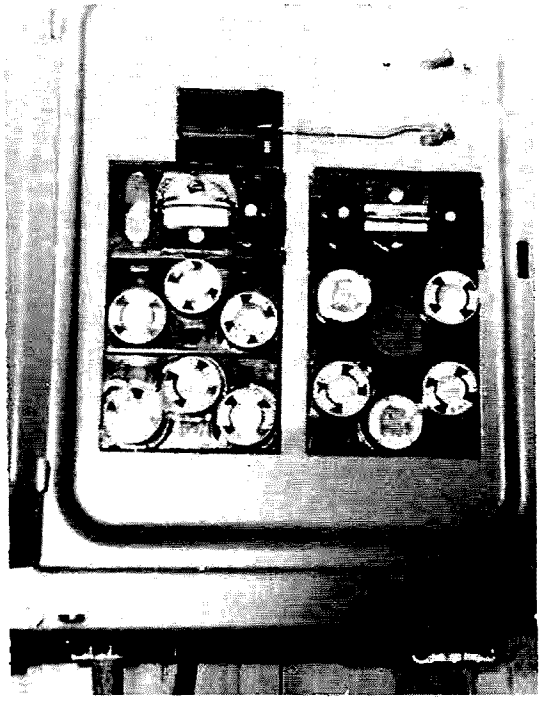


Fig. 1. Residence service box modified for power transfer switching.

economical, switch can be made for the small 115 volt alternators.

I have a hybrid service box with a circuit breaker for main disconnect and fused circuits. An all-breaker box would be wired essentially the same. The fused main disconnect will be described later.

The service box cover was removed and a 30 amp double pole single throw toggle switch was mounted to line up with the circuit breakers. The switch was a surplus unit with holes in the handle. A 1/16" steel rod was formed to make an interconnect between the switch and circuit breakers. The rod must be formed so it won't interfere with the circuit breaker action. With the rod in place, the alternator is automatically disconnected when the main disconnect is on and connected when the disconnect is off. To wire the transfer switch a wiring harness can be made from a piece of No. 12-3 or 14-3 stranded flexible cable. Length will depend on box. An additional two-circuit fuse block was plugged into the service box. If you use this system, be sure the fuses connect to each side of the line. If there are no extra fuse circuits, the alternator can be connected directly to the main bus lines, as it is fused at the control panel. Starting at the fuses, strip and connect the white and black wires. Cut off the green wire. Dress the cable to the alternator input and slit the cable to expose the green wire. Cut the green wire and connect it to the hot alternator input. Make the remaining cable long enough so the service box cover can be removed for service. Strip the white and black wires and connect to the outside terminals of the transfer switch. Strip the green wire and connect to both center terminals of the transfer switch.

Service box modified for power transfer. Note interconnect between main breaker and transfer switch. Signal switch is above transfer switch.

I have not made an installation for a fused main disconnect. Based on my wiring experience (licensed journeyman) the following notes will aid in making an acceptable installation. Bring the alternator input into the service box as with the circuit breaker box. The wiring harness can be a two conductor stranded flexible cable of No.

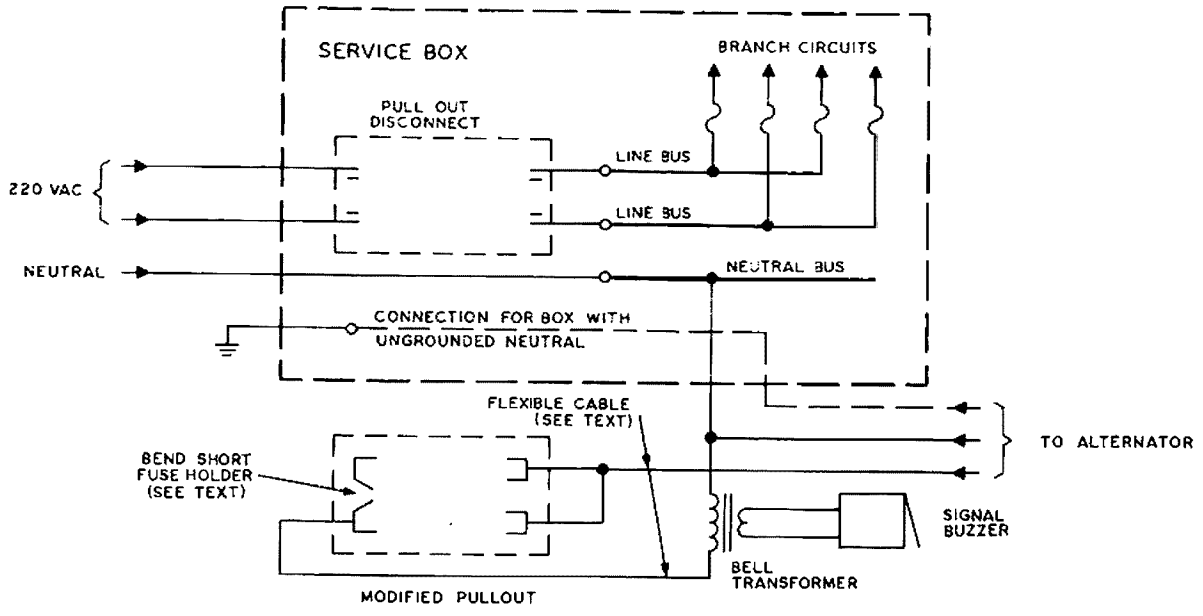

Fig. 2. Alternator connections for pull-out disconnect box.

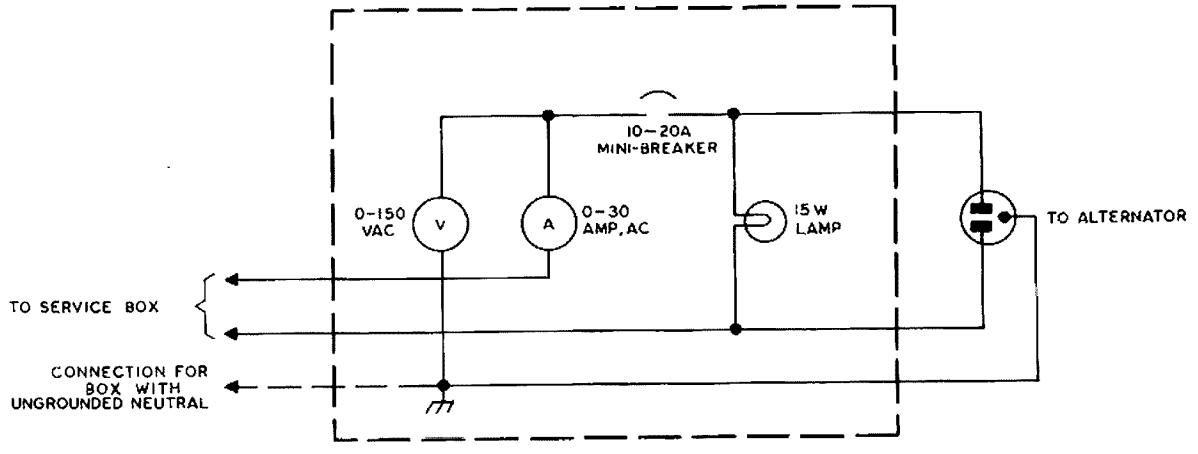
12 or 14 wire for this box. Strip the white and black wires. Connect the black to the alternator input. Bring the cable out of the box and make it long enough to easily reach the main disconnect pullout. Get a replacement pullout and drill it so the black wire can be connected to both fuse terminals on the branch circuit end. Drill the pullout so the white wire can be connected to one fuse holder on the line side. The white wire will be used for the signal system described later. Bend the short fuse holder clip so a fuse cannot be inserted in this modified pullout. Make an insulated (wood is okay) holder for this pullout. The insulated holder will permit test running the alternator with no danger of short or shock to anyone around the service box when the alternator is running.

To transfer the power, the main disconnect is pulled out as usual. Plug in the modified disconnect for alternator power.

There are many other types of residence service boxes. The two described are the most popular in this area. If you have a pull lever for a disconnect, a small two-circuit lever box can be mounted above or below the service box and interconnected with a steel rod.

It is convenient to have a signal system to indicate when main line power has been restored. A bell transformer can be mounted inside the service box and connected to the main line input terminals.

The transformer is on, even with the main disconnect off, so it must be mounted inside the service box. A switch was wired in the



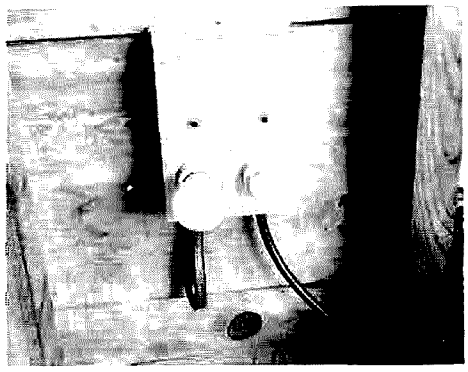


Fig. 3. Alternator panel (optional).

Exhaust wall plate made from 4" junction box cover. See text.

Alternator panel. Voltmeter is on left. Ammeter is on right. The minibreaker screws into a standard fuse holder.

secondary of the transformer to turn the signal off for normal use. A buzzer or bell may be used for a signal. It is not necessary that the transformer be mounted in the box with a fused main as the transformer is plugged in only when the alternator is in use.

The hookups described connect all circuits in the residence to the alternator. A small alternator will not carry all appliances, so a list of appliances to be turned off when using the alternator should be attached to the service box cover.

The second basic precaution is the engine exhaust. Locate the alternator as close to an outside wall as possible, and preferably in the garage of an outbuilding. A small exhaust leak can accumulate lethal quantities of carbon monoxide in a closed area. It is also important to have a free air flow for proper cooling of the engine and alternator. My unit was mounted three inches off the floor to aid in oil changing. A low tone muffler is a good investment. They are considerably quieter than the standard mufflers. A flexible muffler extension for small engines can be made from flexible conduit. Use muffler cement to seal the conduit to the threaded ends. Drill at least a two-inch hole in the wall for the exhaust. A wall plate was made from a four-inch junction box cover with a center knockout.

Two more holes were drilled in the cover for fastening to the wall. Place a pipe coupling against the inside of the plate. The flexible pipe end will thread into the coupling. Turn a pipe nut on a short nipple and thread it into the coupling from the outside and through the knockout hole in the plate. This will hold the exhaust pipe in place. Turn an elbow on the nipple to keep the rain out.

The alternator was fastened to the base with two lag screws. Rubber shock mounts for the lags were made from small sink stoppers.

A control panel was made from a 5 x 7 x 2 inch aluminum box. If meters larger than 2½-inch face are used, a larger box will be required. The panel has an ammeter and voltmeter. The voltmeter is optional. The ammeter is very convenient for checking the load. A minibreaker and fifteen-watt lamp were put in the panel. A flexible lead was made from heavy (14-3 or larger) extension cord to plug the panel into the alternator.

To use the alternator for portable use, remove the lag screws, unplug the cord, remove the elbow, close nipple and flexible exhaust from the engine. This takes about two minutes.

You will find that wiring for the alternator is much more convenient than laying a wire from the alternator to the service box and then connecting it up with alligator clips. Also the family will be able to use it when you are away.

The installation described is for alternators from 1250 to 2500 watts. Smaller units do not have enough output to be worth wiring them into the home electrical system. Larger units are not easily portable (unless trailer mounted) for field day or emergency use.

The new catalog of alternators and supplies arrived after this article was written. Flexible exhausts are now available with standard pipe thread ends in sizes from ½" to 1¼". These exhausts will fit the wall plate described without change.

HIGH POWER MOBILE... THIS TIME THE EASY WAY

Mobiling has always been one of my favorite modes of ham radio. I can remember back in the late forties when I used a low power homemade AM transmitter. My mobile contacts were few and the cost per contact averaged about ten dollars.

Eventually I learned about loading coils, antennas, and mobile power supplies. I began to get good results with my 807, which was later replaced with a 6146. It was about this time that I became employed (previously in school) and I built my first high power transmitter for the 1949 Chevrolet. This final amplifier had four 812s in push pull, was modulated with four 811s and the dc plate supply was an ac 60 cycle power supply using 866 mercury vapor rectifiers. The power source was an old Bendix aircraft 800 cycle alternator that I modified to work from a belt connected to the engine. The centrifugal clutch and carbon pile filed regulator kept the voltage to about 110 volts ac. This alternator also had 24 volts dc available which I used to remotely turn my tuning capacitors with dc motors from the front seat of the car. There were two sets of meters on the transmitter and it was possible to tune the trunk mounted final amplifier from the trunk or the operating position in the front seat. Some wonderful DX was worked from this 1949 Chevrolet but after 130,000 miles and 11 years, I reluctantly removed the rig and bought a new 1960 Chevrolet.

Next I built a small 100 watt 6146 SSB monoband transmitter for this car and I began to see the advantages of SSB mobiling. The results with the 100 watts of SSB was equivalent to the ease of making contacts on the 1000 watt AM rig. Not being satisfied with a single band transmitter I eventually succumbed to a salesman at the used ham equipment counter and brought home a used KWM-1. I could now work three bands and I found my cost per contact had dropped to about one cent. This was quite a change from the beginning.

During the next six years I worked hundreds of stations on the KWM-1 and

hauled it all over the United States. Like all good mobilers, I put off the purchase of a new car as long as possible but in 1966 a new Chevrolet was purchased and the KWM-1 was transferred over.

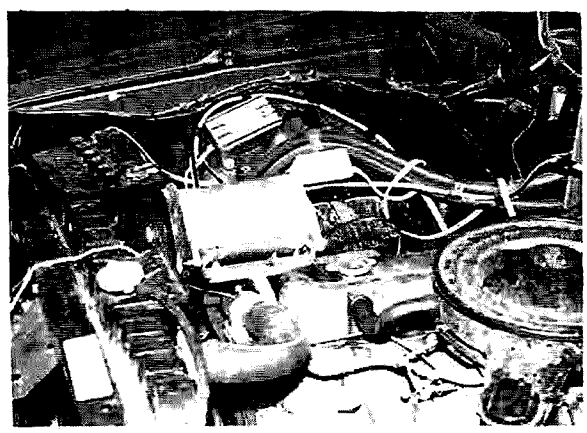
With a new car and all the experience of high powered mobiling of the past, I began to dream of a KW linear for the car. Eventually Heathkit brought out the HA-14 and I was an early purchaser of the gear with its dc to dc transistor converter. A whole new layer of contacts was possible because of the extra "S unit" which set my signal slightly above the other mobile stations. The Heath linear performed very well as long as the power supply held out. Without going into a long story, it can be said that the power transistors in the power supply could not be made to last. Heath was very generous about supplying free replacements of these transistors, but neither Heath nor I ever really succeeded in solving the problem. I eventually decided to tackle the problem another way. I used the 60 cycle ac supply on the HA-14 and installed an ac inverter in the car. This inverter worked well but eventually the transistors gave me trouble and I was forced to turn to other sources for mobile power.

The old Bendix alternator kept coming back to my mind. I really didn't want to put that monstrosity in the new 1970 (yes another Chevrolet) car so I looked around for another rotating power source.

At the Cincinnati hamfest several years ago I saw a remarkable demonstration of a mobile power source (Don Smith, Fairfield OH). A small ac alternator was belted to an automobile and was electrically loaded with twenty 100 watt incandescent light bulbs. This demonstration ran all day continuously without over heating. The alternator was made by Porta-Power of Sarasota, Florida and was made in several power levels from 3 to 4 KW. The alternator had a transistor field regulator to keep the voltage constant at 120 volts. With the variable RPM of the car, the frequency varies over wide limits but since the alternator frequency is always above 60 Hz there should be no problem with 60 Hz ac power transformers. Contact was made with Porta-Power and eventually I was the proud possessor of one of these rotating beauties. This particular alternator was rated at 3 KW. It was mounted as

It seemed that as I grew more interested in high power mobile transmitters that cars grew smaller. I used to be able to sit straight up in a standard Bel-Air, but in the new 1970 my head hit the roof, my knees had to be in a non-vertical position to avoid the steering wheel, and my knuckles disappeared into the dashboard when I shifted gears. I hate to think how a compact car would fit me. The old KWM-1 still performed perfectly after 300,000 miles and I managed to get it mounted on the transmission hump of the car.

Heathkit was now in production with their new 2 KW SB-220 linear and I knew that this piece of eqiuipment had to be my next high power mobile amplifier. When it came to mounting the SB-220 under the dash it was a different story. I did want to be able to see the meters from the driver operating position so I built a small removable table which mounted on the floor under the dashboard on the XYL's side of the car. I might add that the reader might not find their XYL as agreeable, but my wife, W9CNW, was so brow beaten after passing the Extra Class exam that she agreed to let me do this before she had regained her sanity. Photo 2 shows the story. When we are on the air my occasion-



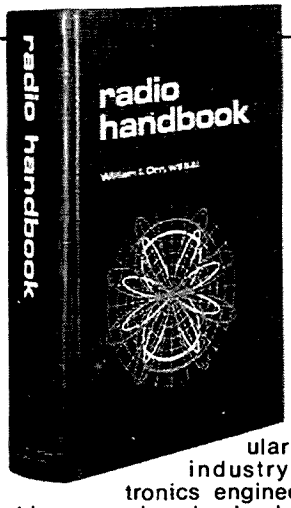


Photo 1. The Porta-Power alternator can be seen behind the radiator and battery. The transistor field regulator is just behind the alternator. The SB-220 is plugged into the 110 volt outlet near the regulator.

Special Prepublication Price
on the completely updated 19th Edition of the E&E
RADIO HANDBOOK

Pre-publication price only

$13.95

By far the most popular manual in the radio industry for amateurs, electronics engineers, and technicians, this comprehensive book has been completely revised and updated by its author, William I. Orr, W6SAI.

LATEST HOW-TO-BUILD DATA

The new 19th Edition of Radio Handbook contains authoritative, detailed instructions for designing, building, and operating all types of radiocommunications equipment. It provides a complete understanding of the theory and construction of all modern circuitry, semiconductors, antennas, power supplies, full data on workshop practice, test equipment, radio math, and calculations.

AN INVALUABLE REFERENCE

Gives the broadest coverage in the field, including the latest information on new high-frequency linear amplifiers of 1 and 2kw PEP output featuring the new 8874 and 8877 tubes, a new solid-state LED-readout receiver, new high-performance 2-meter "moonbounce" converter, and solid-state f-m amplifiers for vhf. All equipment described is of modern design, free of TVI problems. 6½" x 9¼"; hardbound.

PREPUBLICATION OFFER!

al passenger feels somewhat apprehensive when the plate meter reads 3000 volts.

The only modification on the SB-220 was changing the split phase fan motor that refused to turn on the varying frequency of the car alternator. This fan motor was replaced with a 12 volt dc motor which uses rectified ac from a 24 volt filament transformer. The 12 volt fan could have been run on the car's 12 volt system, but I wanted to preserve the ability to run the mobile system on a 60 cycle extension cord when parked at motels.

The results have been all that was expected. DX is very easy to work. I can switch off the linear by a toggle switch on the control box of the alternator. All stations contacted report a change of two S units when the linear is switched off and on. The center loaded antenna is a Master Mobile open coil type. Poor results have always been obtained with other types of loading coils that have solid dielectric. This type heats with rf. No antenna corona discharge problems have been observed.

Mobiling has been particularly good in recent years on Interstate highways. It appears that the metal in the concrete acts as a very good ground plane which gives efficient low angle radiation. Mobilers, let's give those fixed stations some competition. This morning two fixed stations asked two of us mobilers to change frequency. They just couldn't break through our signals.

220 MHz: FRONT END USING FET'S

This article describes the design, circuit, and practical working model for the home brewer. One rf, mixer, and channel-crystal L.O. are used. A second similar rf stage may be used as desired.

Today's FET

The protected and insulated dual gate metallic oxide semiconductor field effect transistor, to spell out just what is inside one of those little tin cans, is shown in symbol form in Fig. 1. This device is good for rf amplification up to 500 MHz, which makes it fine for 146, 220 and 432 MHz.

The main features are high gain, high input impedance, large reduction of intermodulation (which is important today with ever-growing band occupancy and climbing transmitter output powers), no neutralization is required, separate inputs for signal and L.O. when used as a mixer, large dynamic range which also helps on nearby signals, protection from transient HV inputs, and last – but not least – easily applied low drive power agc to keep down distortion on stations a few blocks away.

Design

A good practical, stable rf stage for 220, single wire-coupled to another FET as a

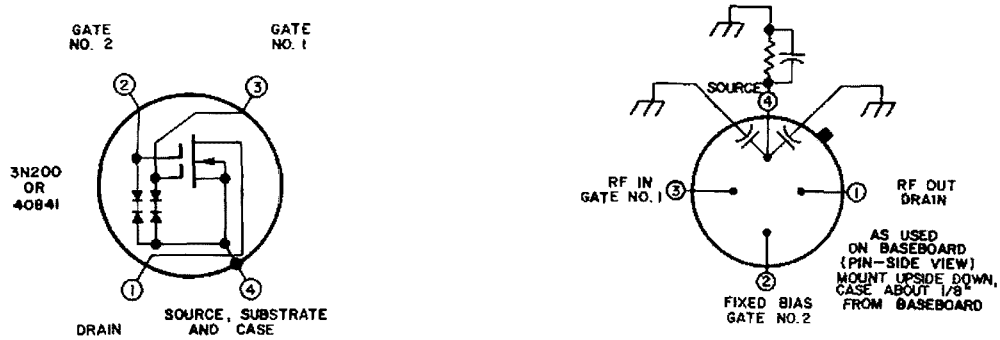

Fig. 1. The 3N200 and its connections when mounted upside down on baseboard.

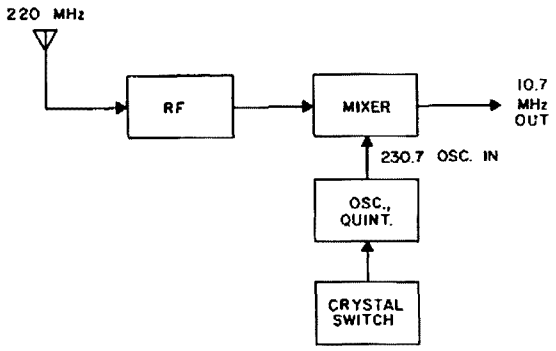

Fig. 2. Block diagram of 220 MHz converter.

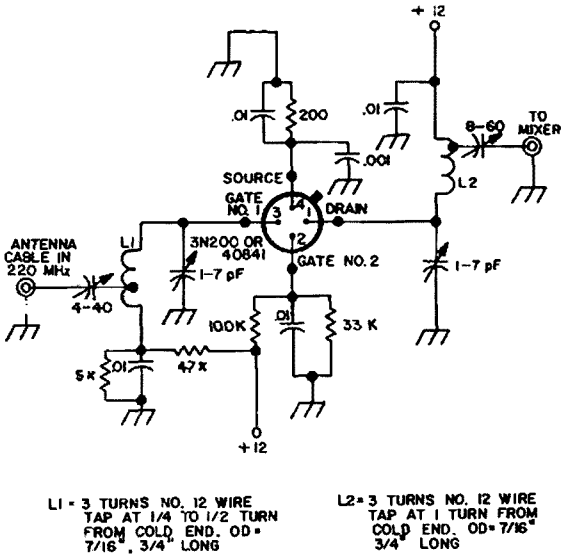

Fig. 4. Circuit of rf stage.

dual-input mixer, and a channel type crystal controlled L.O. are shown. Low cost methods of testing are described, assuming that most do-it-yourselfers, like me, cannot afford signal generators and other test equipment costing hundreds and/or thousands of dollars. This tuner was built and tested with a $30 rf generator and a $14 voltmeter. Because the three are described as separate units and are connected by single wires, no overall schematic is needed (see Fig. 2).

The rf source connection (Figs. 1, 4 and 5) calls for special attention. Use two of the smallest ceramic 1000 (or 10,000) pF capacitors available, about 1/8 in. square, and solder them carefully to the source lead, pin No. 4, as closely as possible to the case. I used Lafayette stock No. 33R69022, to be exact. Then solder one of the capacitor leads to the copper clad baseboard and one to the shield. These leads should tie down the source lead for rf feedback and no oscillation should now occur, even when the input and output are tuned to exactly 220 MHz.

The pictorial layouts shown provide working units and also make good test boards to get together sets of tested and working parts for a final layout. For example, if you wish to make a PC board, or incorporate this circuit into a very small box, the test boards shown allow you to check several sets of components and then, knowing that the coils, capacitors, etc., are correct, install them in the final form chosen. For very small units or PC boards, using pre-tested components also makes for a much neater final job. Every try to modify a PC board?

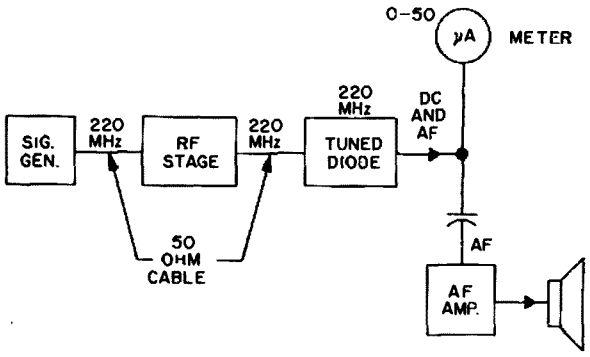

Fig. 3. Test setup for tuning rf stage.

Signal Generator and Test Circuit

The low cost signal generator used here has such a low output on the harmonic used for 220 MHz that it is almost inaudible on a 10.7 diode tuned circuit (see Fig. 3) – without the rf stage, that is. But the amplitude level remains steady, allowing you to build up the stage gains in a relative fashion in good style. Exactly as shown in this article, as in Fig. 3, there is about 4,000 microvolts into the diode which moves the meter in great shape, and the audio signal will drive you out of the shack if you don't turn down the gain. The whole idea of this setup is that you can see everything that contributes to rf gain, conversion to 10.7 MHz in the mixer, matching, and stabilization, which is what you're after here. Also, when everything is tuned and matched correctly, the noise figure will be mainly what the manufacturer says it is. For the 3N200

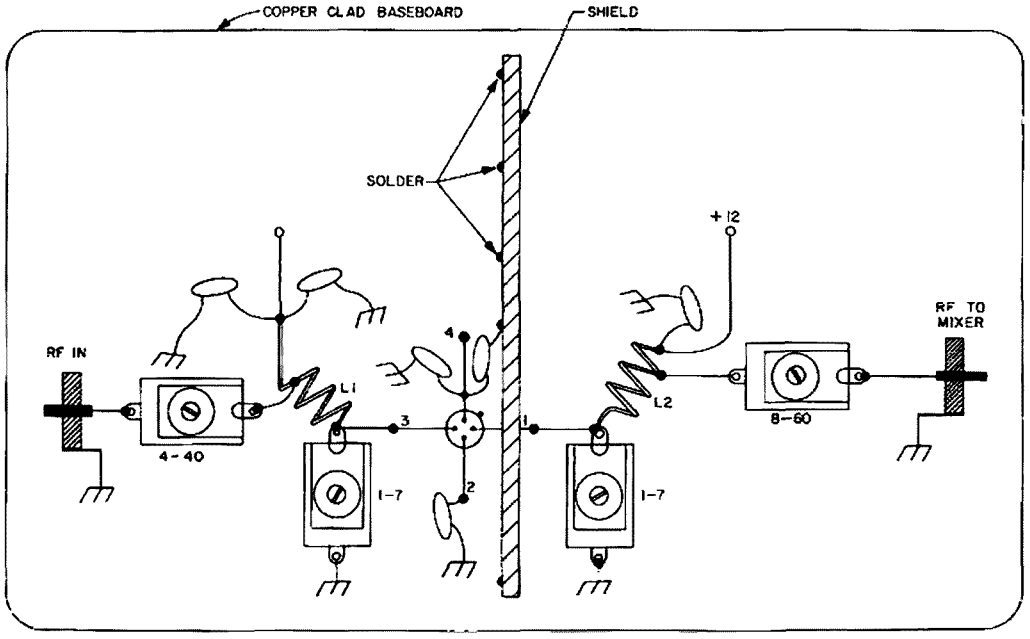

Fig. 5a. Pictorial view of rf stage. Not all parts shown for clarity.

this is somewhere around "typical' 3.9 dB at 400 MHz. For 220 it will be lower and very good. Believe it or not, I can hear radar signals using just one diode for the i-f in the test circuit shown in Fig. 3.

The rf Stage

The schematic is in Fig. 4 and the pictorial layout in Figs. 5a and 5b. This shows the pin view with the signal flowing from left to right. Attention should be paid to the three bias voltages, self bias on the source (similar to a cathode or an emitter) and separate fixed bias voltages on each of the two gates. Bypassing the source is the only real critical point, and if you do it correctly at first you can forget about it from then on. Use several of the smallest available capacitors such as the Lafayette 1,000 pF jobs, which are only 1/8 in. square,

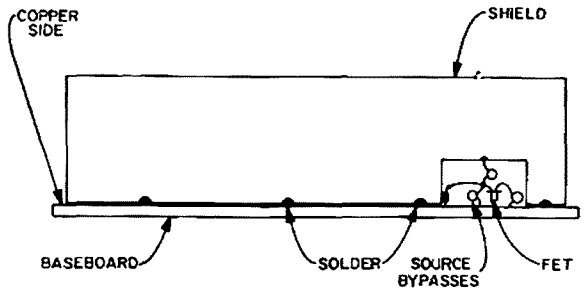

Fig. 5b. Side view of rf stage.

and make the connections no longer than 1/8 in.

Two methods for the input from the antenna are shown because for certain types of antennas one may offer higher gain than the other. Figures 3 and 4 are sufficiently detailed for the rest of the circuit.

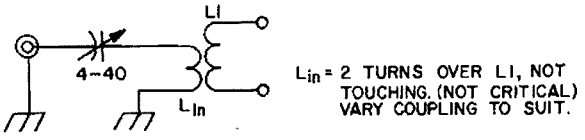

Fig. 6. Alternate rf stage input circuit.

Mixer

There is nothing too critical about this unit, whose schematic is shown in Fig. 7 and the pictorial layout in Fig. 8. Getting the L.O. energy into gate No. 2 must be done with care, however, but once done you can leave it alone. It is important to get *enough* L.O. into the mixer so that you can reduce the amount and still maintain full sensitivity. This means you have some L.O. power to spare, which is good. When you do get sufficient L.O. into the mixer, gate No. 2 dc bias voltage becomes a lot less crticial. The dual gate mixer has shown no tendency to self-oscillate, sometimes a nasty feature with bipolar transistors. Remember, the circuit as shown works well!

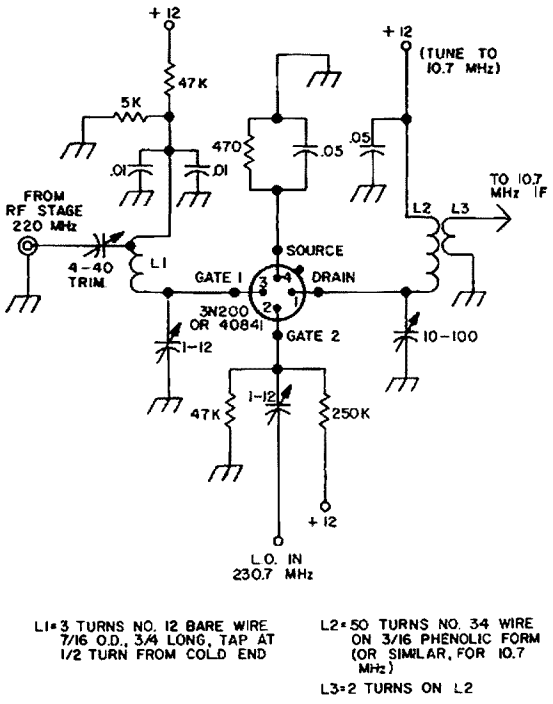

Fig. 7. Schematic of 220 MHz mixer.

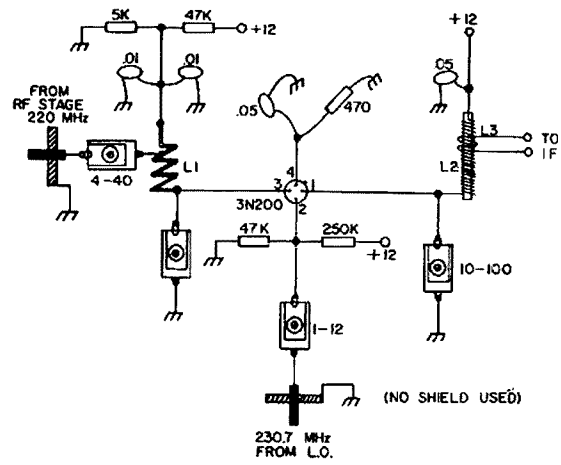

Fig. 8. Pictorial view of 220 MHz mixer.

The Local Oscillator Unit

The schematic is in Fig. 9 and the layout in Fig. 10. This unit, once set up, needs no further attention. After checking the oscillator in the 46 MHz range with a tuned diode, tune the multiplier to 230.7, or a little higher as required by other 220 channels, and that's it. You should get a volt or so rectified dc out of the diode L.O. test circuit shown in Fig. 11. I put in a 2N3866 which is an excellent multiplier in order to get plenty of punch on 232 MHz because the only crystal I had on hand for the 220 band was a 38.667 job, which means multiplying by six. You should order your 220 channel crystals first and use the higher mode (220 plus 10.7). You can get this by quintupling from around 46 MHz, etc. Standard frequency crystals for the 220 FM band channels are shown in the Repeater Bulletin.

You can transfer energy from the quintupler coil to gate No. 2 of the mixer in several ways, but the method shown in Fig. 10 produced the greatest sensitivity. The series coupling capacitor can be used to tune L2. In case it does not, add the optional capacitor shown in Fig. 9. When checking the quintupler for output you should of course use the shunt capacitor to tune L2. Note again that you should have some L.O. power "left over" – otherwise you will not

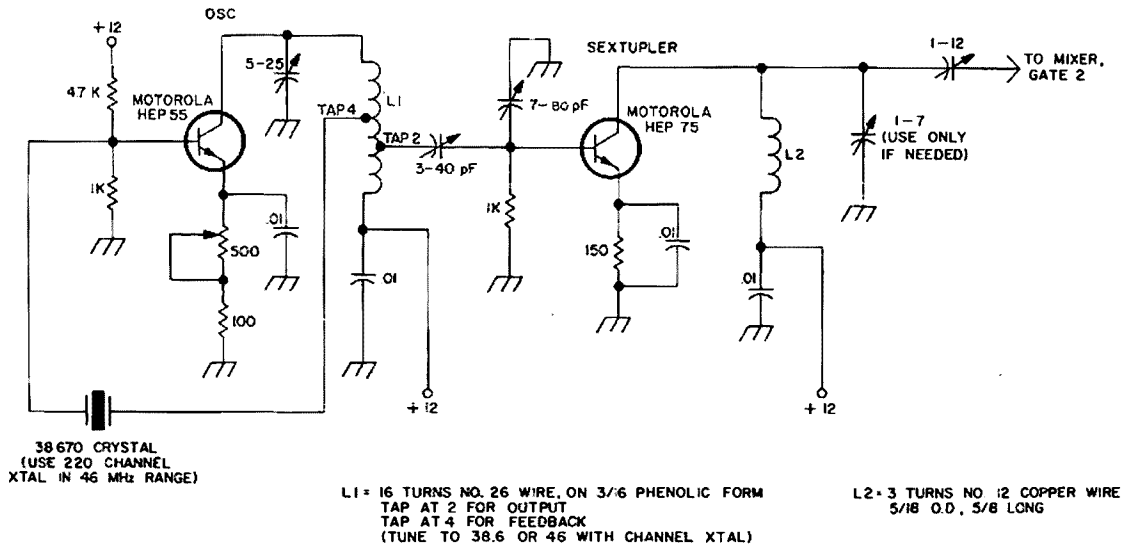

Fig. 9. Circuit of local oscillator chain.

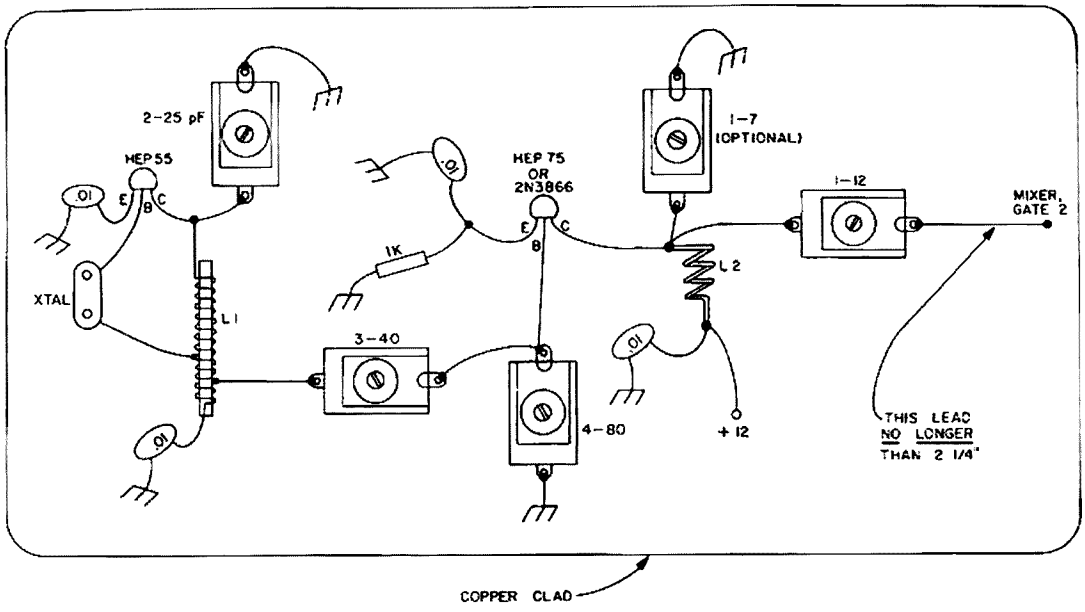

Fig. 10. Pictorial view of oscillator chain. Not all parts shown for clarity.

know if you have enough. You can check this by reducing the quintupler output with a series 1K pot in the emitter of Q2.

The mixer, oscillator and quintupler took about 16 mA at 12V in this unit. The rf stage takes around 6 mA, depending on bias adjustments and the individual FET used.

Figure 12 shows the optional crystal switching and tweaking capacitors that can be incorporated to the circuit of Fig. 9 when you get to where you want to use several channels.

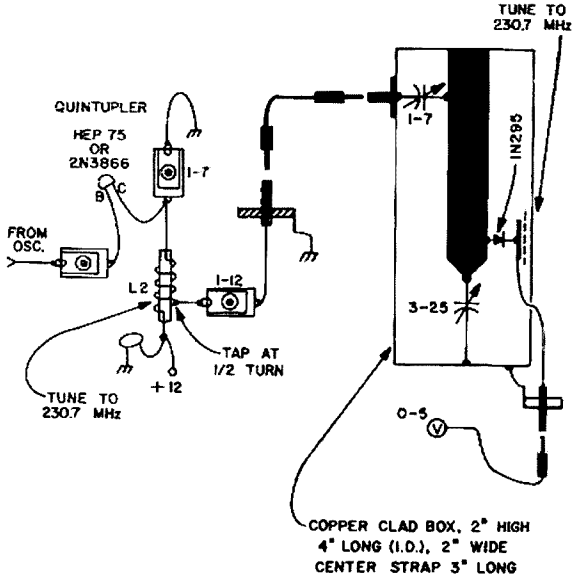

Fig. 11. Diode test circuit for tuning the oscillator circuit.

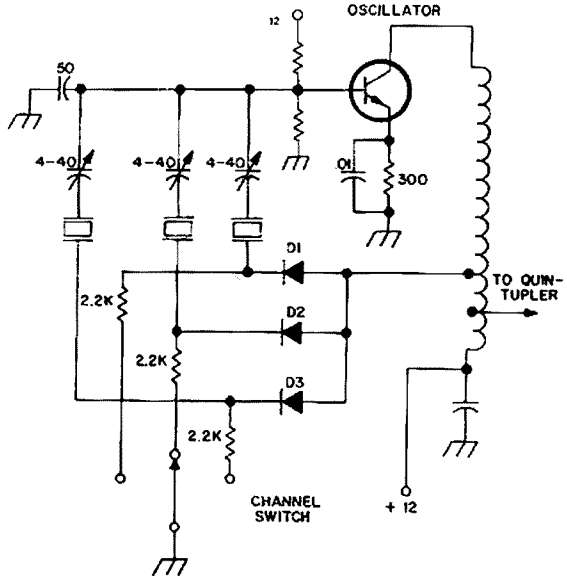

Fig. 12. Optional oscillator circuit incorporating crystal switching and frequency pulling trimmers.

Conclusion

A practical do-it-yourself 220 MHz front end using dual gate FET's has been designed, tested, and described in detail. Built on three separate boards, all components can be checked out in advance for reduction to small size, or PC board work. It is very sensitive, and with just a small vertical dipole you will be able to get acquainted with 220 in your area.

THE DOUBLE DELTA ANTENNA

The Double Delta is a new and unique design which provides both broad-band and efficient performance on the low-frequency bands for a compact, vertically polarized antenna. The ease of tuning and the simple construction are special features.

During recent years many forms have been developed for reasonably compact low-frequency antennas that would exhibit better efficiency than base-loaded verticals, be reasonably broad-band, and have a more predictable and controlled radiation pattern than random long-wire antennas. Various antenna forms have achieved some combination of these electrical qualities, but usually their forms were such as to pose many constructional problems. One example would be low-frequency cage-type vertical antennas. The cone shaped cage requires at least 8 to 16 radial wires, and the open end of the cone must be at the apex of the antenna structure and not at the ground end. Also, a good ground radial system is required for efficient operation of such an antenna.

This article, however, describes a new and unique type of compact low-frequency antenna design which combines many of the features of previous designs but yet is very simple to construct and can have a wide range of physical dimensions. No inductive loading is used in the design, it is reasonably broad-band (over two low-frequency bands with reasonable antenna dimensions), it can be fed with any common transmission line, it has an omnidirectional radiation pattern and the efficiency is good (again with reasonable antenna dimensions) without the use of a ground radial system. Although the design can certainly be used for any fixed station operation, its ease of construction and erection makes it particularly applicable to portable operations.

Basic Design

The design of the antenna, nicknamed the

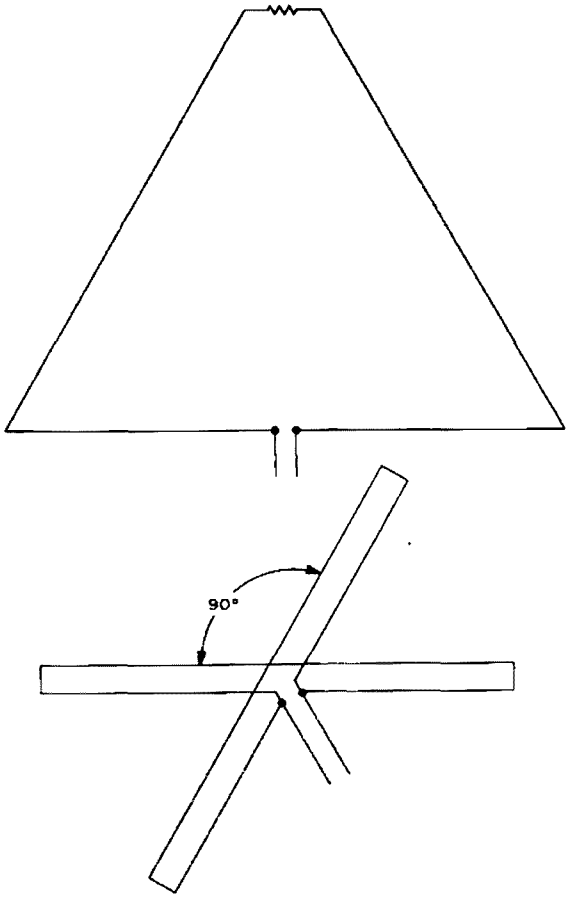

Fig. 1. The Double Delta antenna is basically a combination of a vertical half rhombic design (A), frequently called a delta antenna, and a turnstile antenna (B) made from folded dipole antennas.

Double Delta, was not simply "pulled out of the hat" but is based upon two well established and proven antenna forms. Figure 1 shows these forms. The antenna forms of Fig. 1 (A) may not appear immediately familiar, but it is really just half a terminated rhombic antenna which is vertically oriented, and is frequently referred to as a Delta antenna. It radiates mainly at high radiation angles, and is particularly useful for short-skip work on the lower-frequency bands. In its proper rhombic form and to provide some directivity and gain, the dimensions of the antenna have to be fairly large – at least a 60 ft center height on 40 meters, for instance. However, because the terminating resistor makes the antenna non-resonant, it will accept power over a broad range of frequencies even when its physical dimensions are contracted. The terminating resistor value must only be chosen for given physical dimensions of the antenna. The radiation pattern of the antenna will change as its dimensions are reduced to the point where a small loop configuration is reached. Generally, the vertical plane radiation pattern becomes much broader, and for a given loop or delta size on a given frequency, the horizontal plane radiation may be mainly broadside or in line with the physical plane of the antenna. Such an antenna could be used alone with reduced dimensions, but one real disadvantage would be the radiation pattern change with frequency.

The antenna form of Fig. 1 (B) is that of a conventional turnstile antenna which consists of two half-wave folded dipoles phased so that an omnidirectional horizontal radiation pattern is produced. The necessary phasing is often done with a separate phasing line, but it can also be done by proper interconnection of the dipole feed terminals as shown. When done in this manner, the phasing will remain correct over whatever range the basic dipole antennas can be operated.

Figure 2 shows how the basic two foregoing antenna ideas are combined to form the Double Delta antenna. As can be seen, it

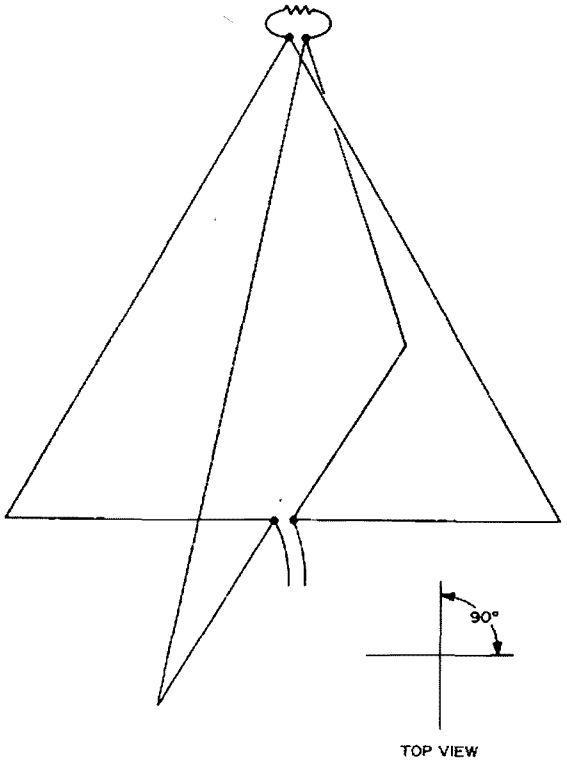

Fig. 2. The Double Delta consists of two Delta antennas placed at right angles to each other and phased in a manner similar to a turnstile antenna.

consists of two single Delta antennas oriented and phased like the dipole antennas in a turnstile configuration. Although the radiation pattern of the single Delta antenna will change with frequency (depending upon dimensions), the turnstile type phasing makes the Double Delta retain an essentially omnidirectional radiation pattern. The use of two Delta antennas further broadens the frequency bandwidth of the overall antenna system. Although a separate terminating resistor could be used in each Delta, the use of a single resistor was found to be sufficient.

No specific dimensions, even in terms of wavelength, was mentioned in the foregoing discussion because, in fact, no hard and fast dimensions can be given. The following section of this article describes a Double Delta antenna which I constructed for use on 80 and 40 meters, but the dimensions shown are by no means the only possible ones. Although studies could not be made of a large variety of antenna dimensions, it would appear that good efficiency will be achieved as long as the total *lineal* length of each Delta element (sides plus bottom section) is made about ¼ wave on the lowest frequency band to be used. The antenna will work with shorter dimensions, but the efficiency will suffer. Probably an absolute lower limit would be to make the lineal length 1/8 wave at the lowest operating frequency. Even with these restrictions, the antenna height required is only a fraction of that of other designs. The ratio of total base length to height (not side length) at the center should not be made greater than a 1:1 ratio. This great latitude in choosing the antenna dimensions is partly possible because the terminating resistor can be "tailored" to suit a given impedance transmission line, and one is not dependent solely upon the antenna configuration to establish the feed point impedance.

Practical "Double Delta" Example

Figure 3 shows the dimensions of one "Double Delta" design which I tried for 80 and 40 meter operation. The total lineal length of each Delta was made about ¼ wave on 80 meters. The base length to height ratio was chosen such that the height was about

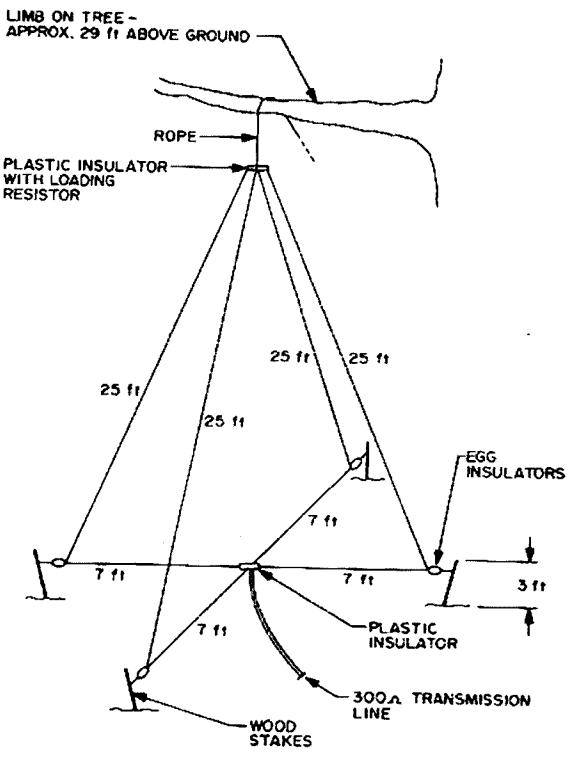

Fig. 3. Dimensions of a Double Delta antenna which was tested. Coaxial transmission line can also be used as explained in the test.

27 ft in order to allow simple erection of the antenna via a rope support around a high tree trunk.

The antenna was constructed of ordinary stranded antenna wire with egg insulators attached to wooden stakes, driven in the ground, used to place the two Delta triangles at right angles to each other. Special plexiglass insulators were fabricated to join the wires at the apex of the antenna and at the base where the transmission line is joined to the antenna. Probably many other schemes can be used for these insulators, but the plexiglass types are simple and inexpensive to fabricate. Details of the construction of these insulators is shown in Fig. 4. The upper insulator joins the individual Delta elements in a criss-cross fashion with the non-inductive type terminating resistor mounted on one side of the plexiglass insulator and connected by jumper wires to the Delta elements. A hole was drilled in the center of the insulator and ¼ in. nylon rope knotted underneath the insulator for use as a support line. The bottom insulator is basically the same as the upper insulator, except that the jumper wires for the Delta elements

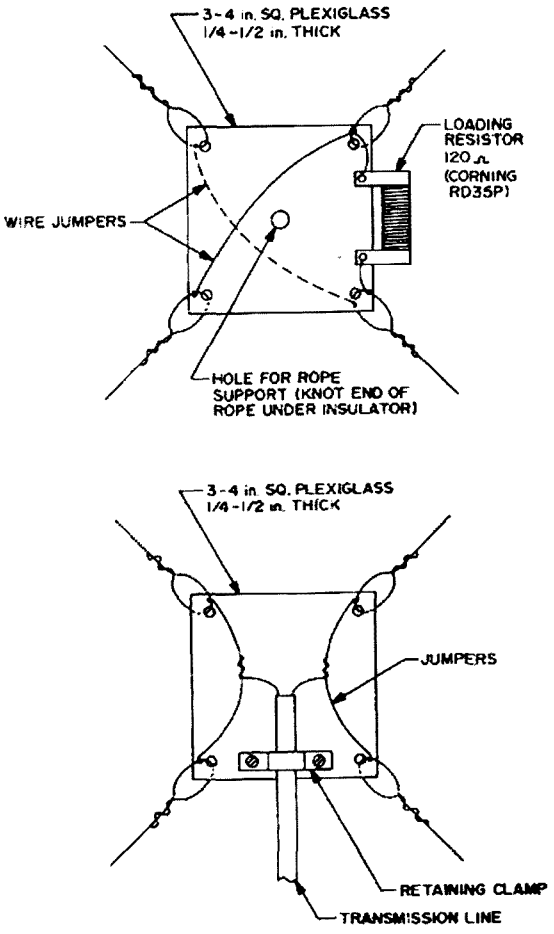

Fig. 4. Details of the upper (A) and lower (B) plastic insulators for the antenna of Fig. 3.

are wired directly from edge to edge. The transmission line used is soldered to the jumper wires and the cable held in place on the insulator by means of a metal or plastic clamp.

Although a 300Ω transmission line was used, any common impedance transmission line, including coaxial types, can be used by properly choosing the value of the terminating resistor. Using 1 or 2 watt carbon composition resistors as test resistors, the value of the terminating resistor can be found which produces the lowest transmission line swr over the desired operating range. Only a few watts of tranmitter power output should be used for these tests (enough power to properly set the swr meter) and then a 25–75 watt resistor substituted for operation at full transmitter power. The wattage rating of the terminating resistor depends upon the dimensions of the antenna, but a safe approach would be to choose a resistor with a wattage rating equal to at least ¼ of the power input of the transmitter used. The 25 watt resistor used with the antenna shown showed no signs of overload when used with a 150 watt transmitter on SSB.

Performance Results

Swr measurements made on the antenna of Fig. 3 showed an swr of less than 2:1 across both the 80 and 40 meter bands. It probably would be possible to further reduce the swr on any one band by more careful selection of the terminating resistor. The total bandwidth of the antenna was not determined, since only 80 and 40 meter operation was of interest. However, there is a good possibility that when properly configured the antenna can be used as a tri-band affair. The only possible disadvantage to such operation is that as the Delta elements become larger in terms of wavelength, one may approach the original vertical half rhombic design with its very high radiation angle.

Comparison tests of the Double Delta design against a base loaded 23 ft vertical made of tubing consistently showed the Double Delta to produce stronger signals on the order of ½ to 2 "S" units.

Summary

The Double Delta shows good promise of being a very useful and simple antenna for use on the low-frequency bands. No claim is made that the optimum dimensions for the antenna have been determined, but the results achieved certainly indicate the validity of the basic design.

Many variations on the basic design suggest themselves, especially if one were interested only in single-band operation. for instance, going back to Fig. 1 (A), one could use a variable capacitor to resonate the antenna "loop style" on a particular frequency. the Double Delta of Fig. 2 could then be constructed with a resonating capacitor in each Delta. This would increase the antenna efficiency by eliminating the dissipation loss in the terminting resistor. However, one would have to accept the feed point impedance thus produced and use a matching network, if necessary, at the feed terminals to couple to a transmission line.

Product Review:

TEMPO FMP

Have you ever had the desire to carry your FM rig at your side to keep in touch with the gang on the local repeater? The Tempo FMP is a convenient way to do it. You can use it over your shoulder or in your car or in your home. Dollar for dollar, it contains many features not found in other rigs.

This little jewel has two power levels. There is the battery saving half-watt out and the fringe fighting three watts out. The half watt is perfect for local direct work or if you are high up in your hotel while traveling. The high power position is great for making the repeaters that seem to be installed on the outskirts of all cities. The high power position is more than adequate for driving amplifiers that require one to two watts of drive. The self contained batteries are C cells that can stand high drain for periods of time. There is even a little switch on the front panel that allows you to change the meter from a S-RF meter to a battery monitor. When you put it in the monitor position, a little pilot lamp is turned on and the meter is illuminated. Besides keeping meters off the batteries and producing a slight drain, you check the battery condition only when needed. The little pilot light is also perfect for lighting up a small area so that you can read your logbook.

There are more channels in this portable rig than there are in some of the available base station rigs. The crystals for the channels are very easily reached. Jumping is simple because there is a lot of room for even the stubbiest of fingers to get in with a soldering iron. All crystals can be trimmed right on frequency. With eight possible channels, you have convenience and versatility. Leave channels one through five for your local work and six, seven, and eight for the channels in the areas that you visit most frequently. Or if you live in the crowded Boston and New York and Los Angeles areas, all eight channels will be filled up for local work.

It may be hard to conceive getting your whole hand into a tiny rig that you can carry around with you, but it is true. The rig comes in two sections that are snapped together. Shades of the low bands, the power and rf units are separate! The batteries and speaker are mounted in the lower box and there is a cable interconnecting the two units. Audio and other leads can be tapped here. There is room for an ac power supply, battery charger, tone burst assemblies, and more in this section. And it is still tiny. The rf unit has the printed circuit boards for the transmitter and receiver and all switches and controls: power, volume, squelch, power level, meter switch, and channel selector. This unit is a little less than half the total size of the whole FMP. You can carry the FMP over your shoulder in its leather case or you can lay it flat on your desk or mount under the dashboard. The antenna connects with a twist on the front panel BNC antenna connector. The FMP is supplied with a quarter wave whip from which kinks may be quickly removed even if you fall on top of it. The shape of the rig is rectangular but with a slightly sloping front panel that leans the antenna away from your body and it also lets the rig look up at you if it is under the dash or on your desk. It looks sharp wherever you leave the radio.

The portable FM transceiver, watertight leather carrying case, and excellently written instruction book costs only $225 from Henry Radio and their distributors. Isn't that a low price for such fun?

A Simple Converter for Beginners

USING EXPERIMENTER'S MODULES

Want to build a converter for any frequency from 3 MHz to 170 MHz? The International Crystal Company experimenter kits can be selected and assembled to make any input and output combination in this range.

A brief explanation of how a converter works will help you understand the functions of the stages. Assume we want to listen to the 20 meter (14.00–14.35 MHz) band and we have an 80 meter (3.5–4.0 MHz) receiver. Our problem is to convert the 20 meter band to the 80 meter band. Subtracting 14.0 – 3.5 we get 10.5 MHz. Note that the 20 meter band is .35 MHz wide. Adding this to 3.5 we get 3.85 MHz. Logically, if we subtract 14.35 – 3.85 we again get 10.5 MHz. We have this constant 10.5 MHz difference at any corresponding points on the bands. If we make an oscillator with 10.5 MHz output and mix it with 14.0 MHz we can produce a beat frequency or difference of 3.5 MHz. Again, any corresponding points on the two bands will have a difference of 10.5 MHz. From this we find that by using a converter we can tune our receiver 3.5 to 3.85 MHz and listen to 14.0 to 14.35 MHz.

We could make a converter with only a mixer and oscillator, but it would have some faults that would limit its usefulness. The first and most obvious is that the 10.5 mixer, or injection, frequency plus the output frequency 3.5 MHz gives us 14.0 MHz which is the desired frequency – but at the same time we have 10.5 MHz minus the 3.5 MHz output frequency which is 7.0 MHz – so we would also be receiving the 40 meter ham band at the same time. This undesired frequency is called the image frequency.

To receive only the 20 meter ham band we need a tuned circuit that will amplify the 20 meter band and attenuate the 40 meter band. To do this we add a tuned rf amplifier stage between the antenna and mixer.

We produce the injection frequency with an rf oscillator. This can be a typical Hartley or Colpitts LC (tuned coil-capacitor) controlled oscillator or a crystal controlled oscillator. The advantage of an LC oscillator is that the injection frequency is easily changed. An adjustable coil or variable capacitor will permit changing the frequency at will. The disadvantage is that it is not as frequency stable as the crystal controlled oscillator. Frequency stability is the advan-

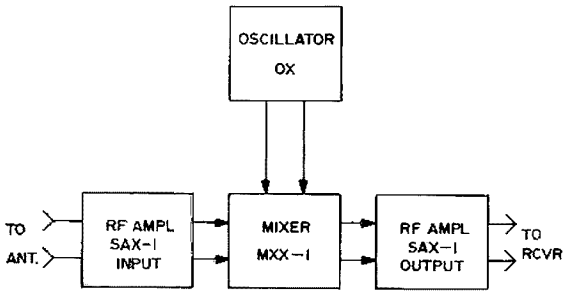

Fig. 1. Block diagram of converter.

tage of the crystal controlled oscillator. The disadvantage is that a new crystal must be purchased to change frequency. This injection or local oscillator frequency is coupled to the mixer where it mixes, or beats, with the signal frequency and produces the output frequency (and image). As the signal input to the mixer is quite small, only a weak injection frequency is required – usually not more than a few mW. You cannot increase the gain of a converter by increasing the injection frequency strength.

We can further improve the gain and signal-to-noise ratio by adding a tuned stage after the mixer. This is an rf amplifier tuned to the output frequency or 3.5 to 3.85 MHz in our example.

We are now ready to begin construction. Refer to the block diagram of the converter (Fig. 1) and Table I to determine the kits to use for the band you want to listen to.

Prepare a 5¼ x 3 x 2 1/8 in. aluminum minibox as shown in Fig. 2. There is room to use any type antenna and output connectors you want. I used Motorola jacks. The switch can be slide or toggle. The miniature imported switches work very well.

Assemble the printed circuit kits with the following changes: The connector pins are inserted in the printed circuit boards when you get them. Carefully push these pins out and reinsert them on the foil side. This will put all wiring inside the minibox and make a neater job. Refer to the charts supplied with the kits for coil and capacitor combinations for the frequency you want. There are several coils and capacitors with each kit. When you insert and solder the coil and capacitor do not bend the coil tabs or capacitor wires. This will permit easy removal if you want to change either for a different frequency.

Table I: Converter Components

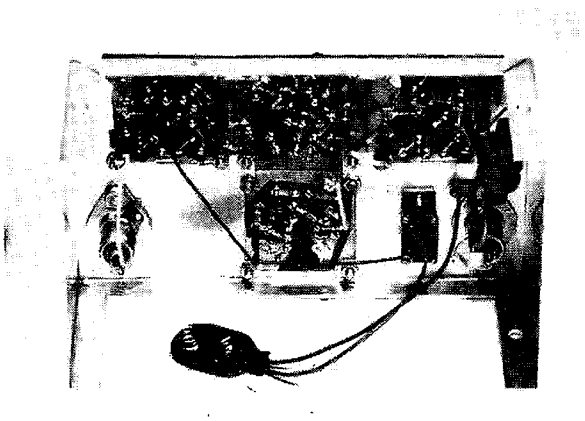
INPUT RF AMPLIFIER

To receive signals 3 to 20 MHz use SAX-1 LO
To receive signals 20 to 175 MHZ use SAX-1 HI

MIXER

Converter input 3 to 20 MHz use MXX-1 LO
Converter input 20 to 175 MHz use MXX-1 HI

OUTPUT RF AMPLIFIER



Output to receiver 3 to 20 MHz use SAX-1 LO
Output to receiver 20 to 60 MHz use SAX-1 HI

OSCILLATOR

Subtract output frequency from input frequency
If difference is 3 to 20 MHz use OX LO
If difference is 20 to 60 MHz use OX HI
If difference is over 60 MHZ divide by 3 and mixer will work on third harmonic of oscillator OX HI

CRYSTAL

Same frequency as difference in input-output above. If difference is over 60 MHz order crystal for 1/3 of frequency difference.

Keeping the above notes in mind, assemble the kits following the directions. The same interconnections and power connections are used with all kits regardless of frequency. The converter I assembled was for 2 meters with a 28 to 32 MHz output. I used two SAX-1 HI rf amplifier kits. One MXX-1 HI mixer kit. One OX HI oscillator kit with a 38.6667 crystal (the crystal is not supplied and must be ordered separately. For the input rf amplifier I used the green dot coil and 6.8 pF capacitor. All the coil designations and capacitors referred to will be from the charts supplied with the kits. The mixer also used a green dot coil and 6.8 pF capacitor. The output is a red dot coil and 47 pF capacitor. The oscillator has a red dot coil and 28 pF capacitor. Slugs were used in all coils except the oscillator coil (there is a further note in the summary about this coil). Make the links from instructions in the charts. The schematic of my converter is shown in Fig. 3.

Mount the kits on the minibox. The mounting screws supplied with the kits are quite long. 4-40 x ¼ in. screws will be neater. Mount the kits so the inputs and outputs line up for minimum connector length. With the three cutouts in front and the oscillator cutout behind, the signal input kit is mounted with the In and Out to the left, rf OUT LINK to the right. The mixer is mounted with the rf IN and GND to the left, GND and OUT to the right. The rf output amplifier is mounted with IN and GND to the left, rf OUT LINK to the right. The OX kit is mounted with the crystal socket to the rear and parallel with the long dimension of the box. Use the press-on connectors for interconnections so the kits can be easily removed if desired.

Step-by-step interconnections follow. If there is a number by the word solder it indicates the number of wires to be soldered at that terminal.

A wire from the antenna jack (solder) to IN connector on input SAX-1 (solder)

A wire from the HI rf OUT link on SAX-1 (solder) to rf IN on MXX-1 (solder)

A wire from LO rf link on SAX-1 to rf GND on MXX-1 (solder)

A wire from rf on OX (solder) to OSC IN on MXX-1 (solder)

A wire from GND on OX (solder) to OSC GND on MXX-1 (solder)

A wire from OUT on MIXX-1 (solder) to IN on output SAX-1 (solder)

A wire from GND on MXX-1 (solder) to GND on output SAX-1 (solder) (note these wires cross, be sure they don't touch)

A 2.5 mH rf choke from HI rf OUT link to LO rf OUT link (solder) on output SAX-1

A .001 mF capacitor from HI rf OUT link on output SAX-1 (solder 2) to converter output jack (solder)

This completes the rf wiring. The remaining wiring is for power to the units.

A wire from one terminal of switch (solder) to 6V on OX

A wire from 6V on OX (solder 2) to + dc on input SAX-1

A wire from + dc on input SAX-1 (solder 2) to + dc on MXX-1

A wire from + dc on MXX-1 (solder 2) to + dc on output SAX-1 (solder)

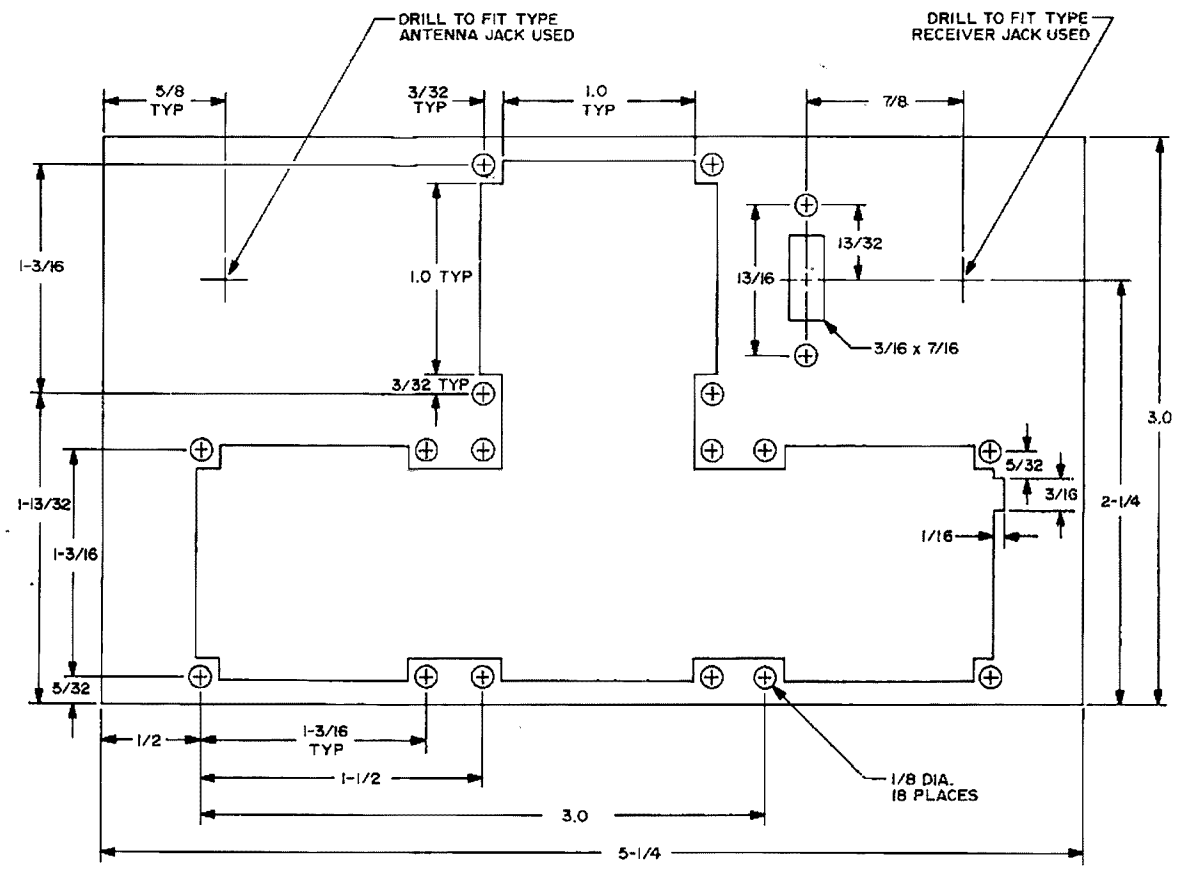


Fig. 2. Template of converter chassis.

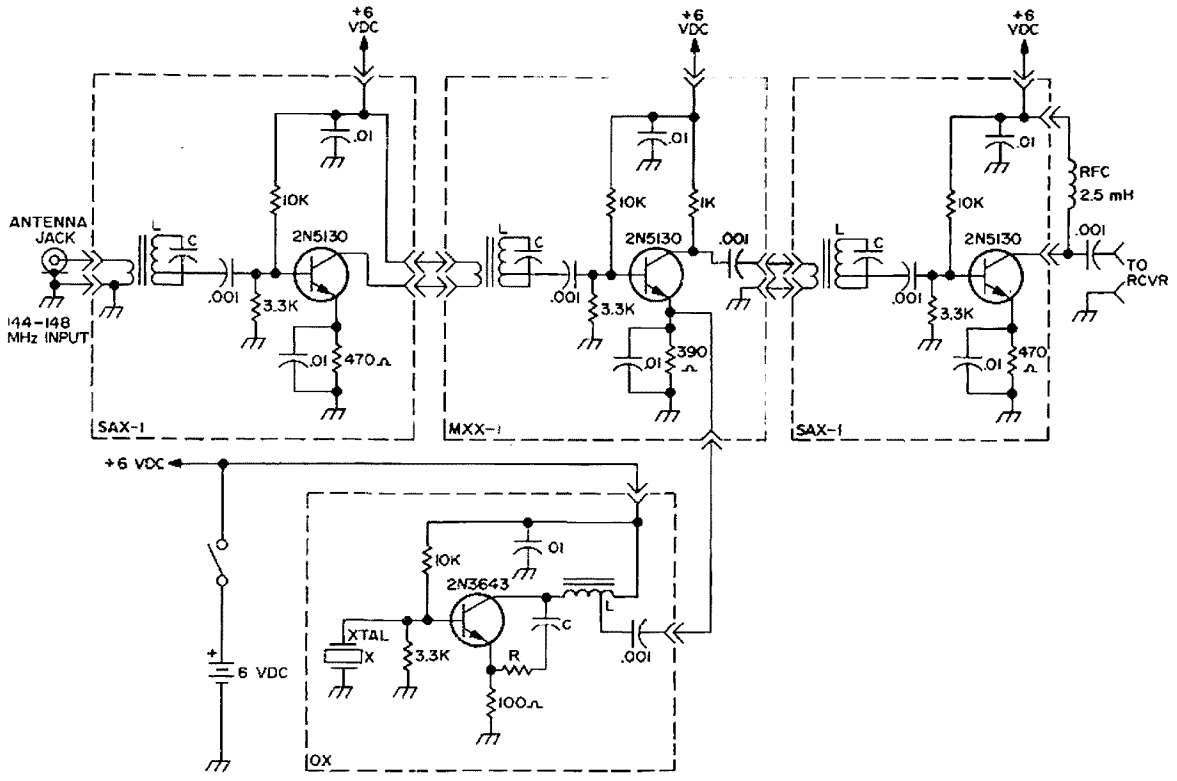

Fig. 3. Block diagram of converter showing overall circuit.

Battery connector leads Black to GND on OX (solder) red to switch (solder)

This completes the wiring. Check all connections to be sure they are correct.

Turn switch off and connect battery. Insert crystal. Center all coil slugs (use a plastic alignment wrench, a metal wrench will affect the tuning). Connect converter to receiver with short piece of coax. Connect converter to signal generator or antenna. Be sure receiver is on correct band. Turn converter on and tune receiver for signal or tune signal generator to correct frequency. When a signal is heard, tune each slug, starting with the signal input coil, for maximum signal. Your converter is now completed.

Some of the frequencies that can be tuned with this convertor are close to the edge of a frequency range for a particular coil and capacitor. If it is and you find that when tuning the coil slugs the signal is still increasing when you reach the bottom of the coil form with the slug, replace the capacitor with the next larger capacity supplied with the kit. If the signal is increasing as the slug is turned all the way out, use the next smaller capacity. Conversely, you could use the higher and lower frequency coils. You should be able to tune through maximum signal strength with the correct coil-capacitor combination. A slug can be used in the OX kit when not specified, if you have the equipment to check maximum oscillation, by using smaller capacitors than specified.

The rf choke in the converter output circuit can be replaced with a coil-capacitor that will tune the output frequency. However, the rf choke and capacitor are satisfactory as is, and no tuning or changes are *required* for any output frequency.

The converter is simple and you can try some of the suggestions in the notes to learn more about converters. The tuning is so simple that if you get "lost" and cannot receive a signal, just go back to the original coil, capacitor and slug tuning and you will be back in business.

There are fine articles in 73 on the construction of converters that will give outstanding performance. After you get familiar with a simple converter – like the one described – you should have less apprehension about building one of the state-of-the-art converters. The only basic difference will be higher 'Q' coils and more tuned circuits with the necessary shielding and bypassing.

THE THIRD HAND..... TESTER

A portable impedance bridge, crystal calibrator, field strength meter, etc.

When was the last time you hung on the tower or in a tree trying to couple your dip-meter with one hand to the bridge which was in the other hand while hanging on with the third hand - not to mention the problem of how to turn the dials while untangling the extension cords (if you had enough to reach) and other associated problems.

The following are construction details for a 3" x 5" battery operated, self-excited built in rf source impedance bridge. With just a little extra effort you can also have a field strength meter with tuned input or use as a band spotter when using crystals at other than their fundamental frequency. You can also check crystals in the 1 to 30 MHz range for activity In addition, with a 1 MHz crystal you have a handy dial calibrator or rf signal source for general allignment and peaking of receiver circuits.

The circuit is a common impedance bridge coupled to, and driven by a built-in

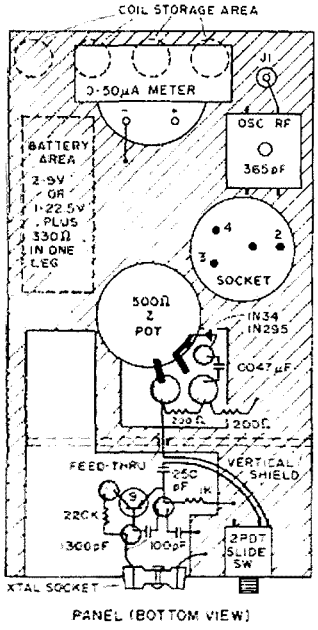

Fig. 1a Circuit board layout. Meter – 0-50μA from mail order listed as light meter movement; 365 pF variable – from old transistor radio socket & coil form allied radio D1899 45d transistor GE9; J1 – pin jack for field strength meter whip antenna.

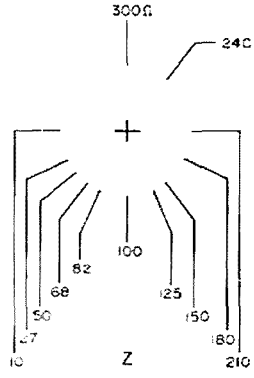

Fig. 1b. Impedance dial scale.

un-tuned crystal oscillator. Any fundamental crystal between 1 and 30 MHz will drive the 50 μA meter to full scale. Inserting an unknown impedance in pins 1 & 3 of the test socket will allow you to read the impedance on the calibrated dial. Should it be convenient to drive the bridge with an alternate rf source such as the transmitter or an rf generator, merely leave the power switch off and inject the rf into pins 2 & 1 of the test socket (pin 1 is ground). Connect the unknown impedance to pins 3 & 1.

To check crystal activity, install the crystal, turn the power on and the relative crystal activity will be indicated on the meter.

To use the tester as a frequency spotter or rf source for alignment plug in the crystal, turn on the power and put a whip antenna in pin 3 of the test socket. For maximum rf output set the impedance dial to 0Ω.

To operate the tester as a field strength meter leave the power off and install a whip antenna in pin 2 of the test socket. For greater sensitivity or band spotting leave the power off, install the whip antenna in the pin jack, and insert the coil for the frequency to be checked in the test socket. Adjust the 365 pF tuning capacitor for a maximum meter indication.

Construction

The complete unit is housed in a 3" x 5½" mini-box. A circuit board may be etched to provide the six islands needed or phenolic vector board may be utilized and solder pins installed in the six locations indicated. The mini-box top is cut away to accommodate the circuit board.

The crystal socket and power switch are mounted on the box end to minimize lead length. The 500Ω potentiometer has one outside terminal cut off to eliminate interference with the diode and .0047 capacitor. If the component placement and lead length and values are as shown, the impedance dial calibration scale provided should be reasonably accurate. A final calibration may be made by inserting precision resistors in pin 1 & 3 of the test socket and comparing the null obtained to the dial readings.

The whip antenna is a replacement type available for transistor radios. Obtain a broken TV rabbit ear from the local repair shop (lots of 'em) and solder a pin jack to the broken end. Hint – file away the chrome finish before attempting to solder.

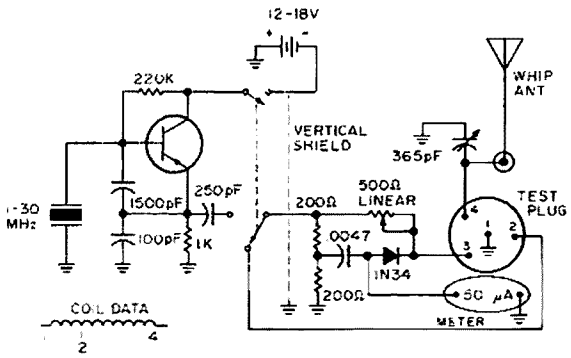

Fig. 2 Schematic 3 – 7.5 MHz 35 turns No. 24 tap 12 T. from ground end. 6 – 14 MHz 20 turns No. 24 tap 7 T. 13 – 22 MHz 11 turns No. 24 tap 4 T. 21 – 30 MHz 6 turns No. 24 tap 2 T. All coils on Calectro G-C No. DI899. Available from Allied Radio Corp. Meter 0-50 μA. Available through mail order houses as light meter movements. CHEAP! 365 pF tuning capacitor is from an old transistor radio. Don't use the oscillator section or frequency coverage will be higher than indicated. Transistor – GE9 or similar. The power/function switch is a slide type 2P2T miniature. Whip antenna: rabbit ear or similar device (see text).

As indicated on the schematic, two 9V batteries may be used for power or one 22½V battery with a 330Ω series resistor in one lead. Current drain is approximately 8 mA.

Four plug-in coils are needed to cover the range of 3 to 30 MHz. Using the coils specified you will find ample room inside the mini-box to store the coils vertically when they are not needed. To secure the coils I merely cemented a piece of foam rubber to the cover and standing the coils up allows the pins to rest in the foam when the cover is installed.

A standard fuse holder (open type) was mounted on the outside of the box and makes a convenient holder into which the whip antenna may be snapped. Should you desire real accuracy from the 1 MHz crystal for dial calibration purposes, the 100 pF capacitor off the transistor base may be made variable and the crystal can be beat with WWV. Considerable adjustment may be made without effecting rf output or frequency range of oscillation.

HIGH STABILITY "LUMPED LINE" OSCILLATOR

Many self-excited oscillator circuits have stimulated the interest of the designer and constructor. Each of these can be readily optimized for a particular performance feature, or exploited for some practical advantage. When frequency stability commands high priority, the Clapp oscillator is likely to be the chosen circuit. Although it has been shown that the attributes of the Clapp circuit can be attained by directing special design approaches to other configurations, the fact remains that frequency stability is a readily forthcoming operating feature of the practical Clapp oscillator. It is for this reason that this circuit is so frequently used as vfo in both amateur transmitters and commercial equipment. When one considers the extent and tenure of the popularity enjoyed by the Clapp oscillator circuit, the question naturally arises, "Does the possibility exist for further upgrading of self-excited oscillator performance?" In the exploration of such a possibility, we would not be concerned with such techniques as temperature compensating components, regulated power supplies, feedback limitation, etc. These performance-enhancements can be applied to *any* oscillator circuit. Rather, we would like to see a new or modified approach which would possess inherent virtues *prior* to application of such compensation and optimization methods.

In seeking to displace or improve the basic Clapp circuit, it is only apropos that we first cite some of its real or alleged shortcomings. The most obvious one is likely to receive the least attention because of general acceptance as the "nature of the beast." In the Clapp, as well as in all other self-excited oscillators employing L-C frequency determining "tank" circuits, oscillation frequency is profoundly susceptible to conditions associated with the inductor. This sensitivity includes turn-spacing, dieletric between turns, moisture, dust, temperature,

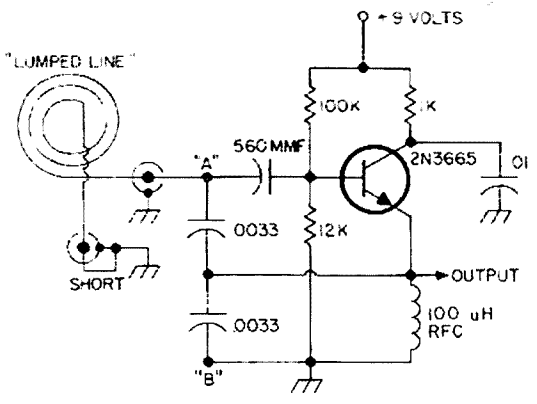

Fig. 1. Basic "lumped-line" oscillator. Tank circuit has apperance of conventional coil but functions as full-wave transmission line with no exposed high-impedance or "hot" points.

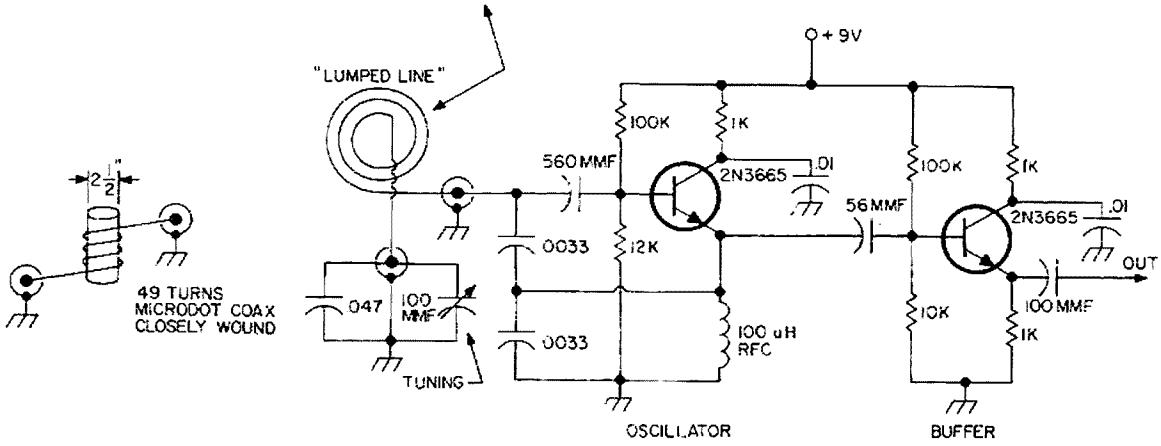

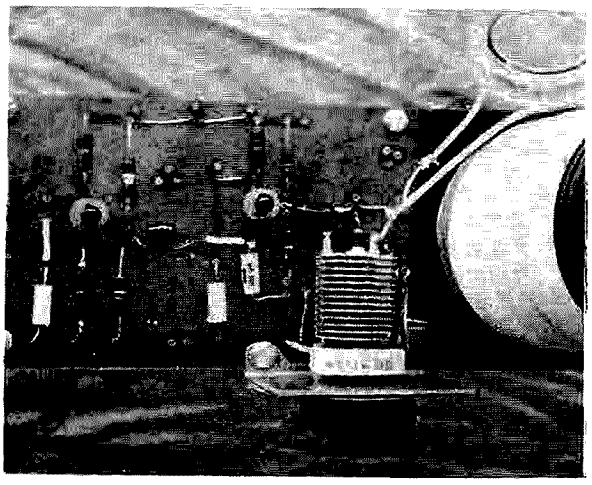

Fig. 2. Lumped-line oscillator with tuning provisions and buffer amplifier. Circuit values shown for 21 MHz oscillator.

proximity of conducting surfaces, and mechanical vibration. In the Clapp circuit in particular, the juncture of the inductor and the resonating capacitor is at a very high impedance level and displays very high sensitivity to stray capacitance. Awareness of these matters leads to defensive measures such as rugged construction, shielding, short leads, etc. But would we not have a more desirable situation if "built-in" immunity against frequency change could be achieved? This seems to suggest a different type of resonant circuit. In what follows, the revival of an "old-hat" approach may suggest itself. However, if attention is focused on the *mode of operation* involved, it will be seen that the described oscillator embodies a combination of theoretical and practical approaches which makes it unique and, to the best of my knowledge, is not to be found in the technical literature.

Oscillators employing *transmission lines* are well known. Chief claim to fame here stems from the high Q attainable from lines, especially at the higher frequencies. The quarter-wavelength resonance generally utilized has precluded the construction of such oscillators for use below the vhf region. too, the general design approach of such oscillators has endowed them with familiar shortcomings. The obsession with push-pull configurations results in "hot" lines wherein the detuning effect of the immediate environment is much in evidence. The high impedance end of the quarter-wave lines is associated with the active device and thereby becomes very susceptible to frequency pulling. Moreover, such an association with a transistor would be even more detrimental than with a vacuum tube. On the basis of such facts, the usual substitution of a resonant line for an L-C tank circuit constitutes neither improvement nor innovation. But the transmission line has not been brought up for the sake of rejecting it! When one considers certain properties of such lines, it becomes apparent that conventional line-type oscillators *do not advantageously use these properties.*

The reader should by now be prepared for some kind of marriage between the Clapp circuit and a transmission line. This, indeed, is the destination of our discussion, but we shall direct our attention not to the conventional quarter-wave line, but to the full-wave line. Whereas odd quarter-wavelengths simulate the parallel resonant condition of an L-C tank, even quarter-wave lines simulate the condition of L-C series resonance. Let us further stipulate that our full-wave line be coaxial cable. For the

moment, we will deal with the simple full-wave coaxial line shorted at the far end. Inasmuch as we will be interested in establishing full-wave resonance at least as low as the amateur forty-meter band, we can make use of one of the Microdot miniature coaxial cables, and wind it solenoid-fashion around a cylindrical form. Now the cat is out of the bag: We have a "coil" which behaves as a series-tuned tank circuit and is therefore suitable for use in the basic Clapp circuit. *Yes, but what a coil this is!* It possesses the following features:

It can be wound on either a metallic or insulating form.

Its resonance frequency is not influenced by turn spacing, turn diameter, or winding length.

Its resonance frequency is not influenced by surface dust or moisture.

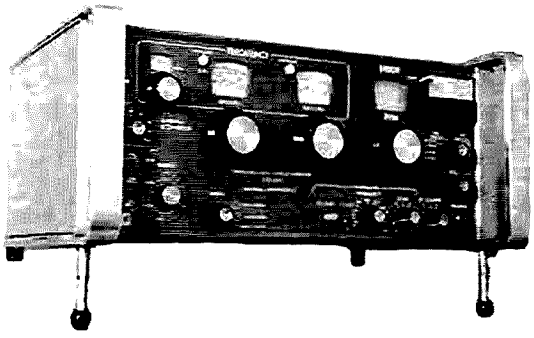
It will not participate in undesired inductive or capacitive coupling to other parts of the circuit.

The entire length of the outer sheath is a rf ground potential and there are no frequency disturbances from proximity effects.

It displays virtually no microphonic effects and is very nearly immune to mechanical vibration.

Its temperature coefficient is relatively low, being a calculable function of its change in end-to-end length.

There is no "nerve ending" in the form of a high impedance junction.



Such a line is "happy" to work into the low impedance input of a transistor.

Reasonable compactness is readily attained. Layer winding may be employed for lower frequencies.

Nearly complete shielding with no reduction of "Q."

The circuit of the basic "limped line" oscillator appears in Fig. 1. From the viewpoint of the active device, i.e., the transistor, a series resonant "tank" circuit is seen from points A–B. This being the case, oscillation occurs in the same manner as in a Clapp oscillator. Although the circuit has the same configuration as a conventional Colpitts with a resonant line operating in the quarter-wave mode (simulating a parallel-tuned L-C tank) such operation is here ruled out by the *very*

large capacitors across the open end of the line. These capacitors tune quarter-wave resonance to such a low frequency that the circuit Q is too low to allow oscillation to occur. Indeed, the purpose of these inordinately large capacitors is to all but short out the transistor end of the line! This of course is perfectly agreeable to a line which operates in a mode simulating a series-tuned L-C tank. And why not use the line in the half-wave rather than the full wavelength mode? Although transmission line operation is *similar* in all multiples of one half-wavelength, it so happens that the phase-relationship between voltage and current is suitable for oscillation in this circuit only for even multiples of one-half wavelength. So a *full-wavelength* line is the shortest one which will function in the simulated series-resonant mode in this circuit.

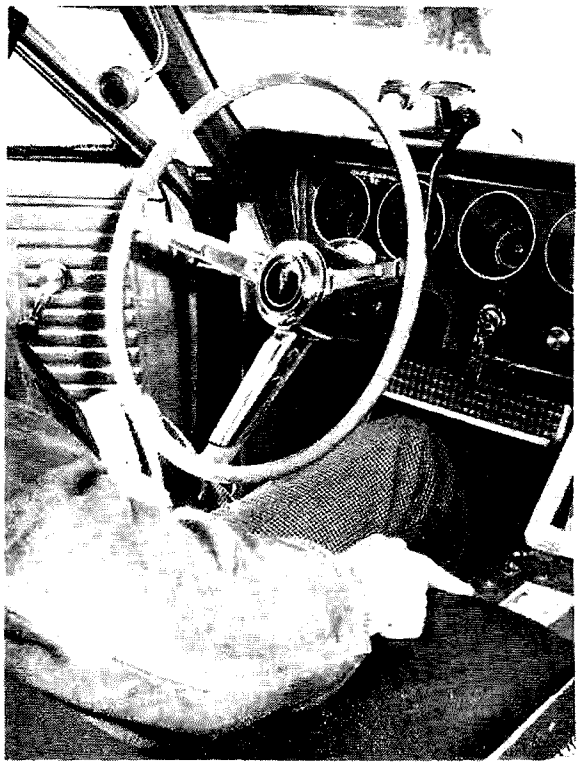
Digressing back to LC tank circuits, the usually cited formula for parallel resonance is: $fo = 1/2\pi\sqrt{LC}$ but the true formula is actually: $fo = \frac{1}{2\pi}\sqrt{LC(\sqrt{L-RL^2C/L-RC^2C})}$ where R_L and R_C are respectively the equivalent series resistance of the inductor and the capacitor. Although R_L and R_C can often be considered negligible in order to enable the use of the simpler formula, the true formula clearly shows that the frequency of parallel resonance is affected by tank circuit losses. Conversely, the frequency of a series resonant tank circuit losses. Conversely, the frequency of a series resonant tank is not per se directly detuned by resistance associated with the tank. Although the Q is adversely affected in both types of resonances, the series-tuned type is more likely to be superior in providing an oscillator with immunity against frequency instability. I have found this to be the case too when one compares the resonant line in terms of simulated parallel and series resonances! Thus, in Fig. 1 a resistance low enough to almost stop oscillation can be placed across the transistor end of the line with very little effect upon the frequency oscillation.

In order to make the basic "lumped-line" oscillator of Fig. 1 more adaptable to practical applications, an emitter-follower buffer stage is added. This stage is operated as a class A amplifier in order to provide good isolation from subsequent circuitry. Power output is purposely kept relatively low – several tens to several hundreds of milliwatts. This enables us to greatly minimize certain thermal problems which tend to adversely affect any oscillator. It is simple and inexpensive to boost power level via tuned class C amplifiers and generally proves more satisfactory than trying to squeeze the requisite watts from an oscillator, whose chief mission in life is frequency stability. Also, a tuning adjustment can be added. This control should not be expected to provide a wide tuning range, but rather a change in frequency comparable to that needed to tune across the amateur bands. Here again we find a very advantageous situation. By replacing the shorted end of the line with a large capacitor in parallel with a small variable capacitor, both the rotor and stator of the variable capacitor will be at low impedance relative to ground. Here again we avoid sensitivity to proximity effects. Figure 2 shows both the emitter-follower and the tuning provision.

The circuit is sure-fire and shows no indication of being critical. It should yield readily to various modifications to comply with the constructor's specific needs. One thing is mandatory, however: *Be sure to ground the coaxial line at the near end,* i.e., the transistor end. The far end can then be grounded also. If the far end *only* is grounded, the circuit may oscillate at a relatively low frequency determined by the inductance of the "coil" of coax and the associated capacitors. When the near end is grounded, the coil configuration of the coaxial cable has no effect upon oscillation frequency.

. . .W6HDM

Calculation of Frequency of Oscillation



1. Wavelength = physical length/velocity of propagation where velocity of propagation is approx. 0.66 times the free-space velocity.
2. λ = wavelength in meters = π X N X D/39.4 X 1/0.66
   For our experimental oscillator:
   N = 49 turns of Microdot coaxial-cable
   D = 2½" diameter
   39.4 factor converts inches to meters
   then $\lambda = \pi$ X 49 X 2.5/39.4 X 1/0.66
   λ = 3.14 X 49 X 2.5/39.4 X 0.66 = 14.75m
3. f = frequency in MHz = 300/λ = 300/14.75 = 20.3 MHz

A MOBILE BASE STATION

Many was the time when you wanted to be mobile with the comfort of a base station. Since I spend a lot of time in my car I decided that I would do something about it. Using a piece of coat hanger I made a shape of the seat of the car and cut two side panels, a bottom and ends. I had an arm rest with a padded top cover and an auxiliary glove compartment underneath.

Since the push-to-talk mike is very bad in traffic, I got a small flexible boom (from a small lamp) and mounted it at the same spot as the left hand sun visor. No holes had to be drilled in the car for this. A bracket was made to mount under the sun visor bracket. When not in use the mike clips out of the way onto the sun visor. The mike used cost $5.00 and is tapped to hold the flexible coupling. The mike is a high impedance magnetic (Japanese DM-175 made by Primco Co. Ltd.). The mike switch and a touch tone pad are right at the finger tips when my arm is at rest. An indicator light shows that the mike is in use. This set up is so convenient that while operating you can concentrate on driving with both hands when necessary and it's very safe. Even in a quick stop the mike just goes out of the way when it gets hit because it is so flexible.

TEN - ROGER

Every now and then, amateur radio magazines print articles about other radio services of interest to amateurs. This article is intended to brief you on the state of the Citizens Band. Why? You may wish, as I have done, to tune around the 11 meter band in the United States or Canada and see for yourself what is going on. You may wish to join them. On the other hand, you may wish to prepare yourself for the day when they might join us on 220 MHz.

The title of this article is taken from the current form of receipt on the Citizens Band . . . sort of a cross between Ten-Four and Roger.

Skip vs Local

The FCC Rules and Regulations permit only local communication within a 50 mile radius. While only a three day sample was taken, about 98% of the stations heard were working skip. At one point, a station was heard telling someone about another station working local on a "skip" channel.

Channels

Class D Citizens Radio channels are assigned as follows:

1	26965 kHz	13	27115
2	26975	14	27125
3	26985	15	27135
4	27005	16	27155
5	27015	17	27165
6	27025	18	27175
7	27035	19	27185
8	27055	20	27205
9	27065	21	27215
10	27075	22	27225
11	27085	23	27255
12	27105		

When skip is in, all 23 channels are solid heterodynes. To avoid congestion, some stations operate halfway between the channels. Others operate out of band from 16915 to 26995 and 27235 to 27275 kHz. There is also some voice operation in the five Class C channels (26995, 27045, 27095, 27155 and 27195 kHz) reserved for model airplane and other control purposes.

Power

FCC Rules and Regulations limit the transmitter power to 5 watts input to the final amplifier. Serious CBers regard this restriction suitable only for exciters. Some talk cryptically about "having a little help on the side" or make passing remarks about having an afterburner. Others may be heard carrying on a discussion of the merits of a pair of 813's vs a 4-400.

Profanity

From some remarks made by other amateurs, I was prepared to hear a considerable amount of profane or indecent language. In three days of monitoring, only one such outburst was heard. Instead, it appears that the CBers have built up a preferred list of euphemisms for use on the air. These include: Cotton Picking; By Golly; Doggone and Mercy (sometimes repeated or followed by the words Sakes or Me).

Tones

A number of different types of tone signaling may be heard. No doubt most of these are for selective calling. Two stations were heard making long transmissions of swept tone electronic sirens similar to the type used in pilots' survival radios. The purpose of these transmissions could not be determined. However, one might speculate that a siren could be used to "clear" a channel, to override interference, or simply to "do one's thing."

Operation

Undoubtedly there is some sense of accomplishment after one has assembled a 23 plus channel transceiver, a kilowatt afterburner, a 3 element cubical quad and mounted it on a new 90 foot tower. However, the enjoyment in CB comes mainly from operating.

Efficient operation on the Citizens Band depends on short, push-to-talk transmissions. This technique is necessary to cope with the severe co-channel interference and reduces the likelihood of being DFed.

It is also necessary to cultivate a "country" accent and develop a repertoire of folksy sayings, like: "If the good Lord's a willin' an' the crick don't rise." It is customary to refer to another CBer as "good buddy," "ole buddy" or "you cotton picker." "You loudmouth" is equally endearing but carries the added meaning of good signal strength.

Operating Procedures

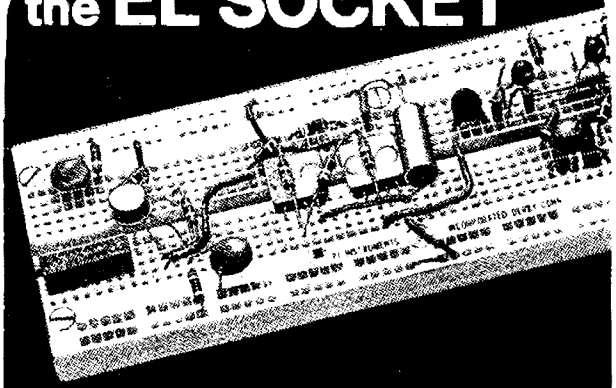
The following is a primer on current CB operating procedures:

Calls: A general call may be initiated by transmission of BREAK BREAK BREAK. For variation, the words BREAKER or BREAKETY may be substituted. This is followed by the identification of the calling station as well as the general location and an invitation to transmit.

Station Identification: The word HANDLE is used to refer to the tactical call sign selected to identify the station. Care is taken to avoid duplication. Typical call signs are: GRANDADDY LONGLEGS, SNAKE EYES, DOG CATCHER, OKLAHOMA OUTLAW, BROOMSTICK, JITTERBUG GIRL, ARKANSAS SAILOR, DIRTY BIRD, CHICKEN HAWK and MUD TURTLE.

Location: Station locations are given only in general terms. Normally it is localized only to the part or quadrant of the state or province. The name of the state may be given, but giving its nickname (e.g., the Buckeye State) is considered to be more innovative. In large metropolitan areas, the name of the city may be given. References to the CBer's house may be made by the term HOME TWENTY or BASE TWENTY, which doubtless are mutations of the amateur radio expression "HOME QTH." For the purpose of exchanging WALLPAPER (QSL cards), it is customary to use a post office box, preferably at a post office some distance away.

Invitation to Transmit: The equivalent of the amateur K or OVER is COME ON, COME BACK, or COME ON BACK. HOW 'BOUT IT may also be used.



Typical Call: BREAK BREAK BREAK THIS IS THE OLD RIVER SNAKE IN NORTHEAST FLORIDA COME ON.

Replies: Replies consist of the words HOW 'BOUT IT (or THAT), the identification and/or location of the called station, similar information on the calling station followed by an invitation to transmit.

Typical Relay: HOW 'BOUT IT RIVER SNAKE DOWN THERE IN NORTHEAST FLORIDA THIS HERE'S THE OLD BROKEN WHEEL UP HERE IN SOUTHEAST NEW JERSEY COME ON BACK.

Signal Strength and Readability: Signal reports are not as formalized as on the

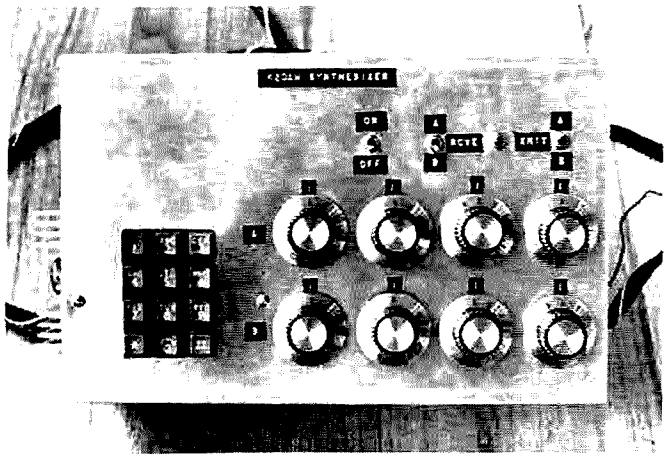
amateur bands. Reports such as YOUR SURE HAVE A BODACIOUS SIGNAL UP HERE or YOU'RE WALKING ALL OVER THEM are used. Others are: GOT A GOOD COPY ON YOU, YOU SOUND LIKE A LOCAL, and YOU WIPED THE CHANNEL CLEAN. The "S" meter system of reporting signal strength is used to some extent. This is normally restricted to the upper part of the scale in dB's over S9.

Messages: Messages consist of informal conversation between the two stations in communication. These transmissions are called MODULATING. Much of the exchanges center around discussions of the amount of interference on the channel. Another general topic is the weather in the vicinity of the HOME TWENTY.

Reports: Procedures for requesting repeats are informal. A request for the other station's location may consist of WHERE YOU AT? A general request for a repeat may be made by transmitting ONE MORE TIME.

Receipts: Receipts are normally given for each transmission. TEN-ROGER is normally used for this purpose. The words ROGER and TEN-FOUR, though deprecated, are still in use.



End of Transmission: At the end of the contact, it is customary to thank the other station and wish him well. The other station may be told GLAD YOU COULD MAKE THE TRIP. A station may also say that we would welcome seeing the other station sometime later ON THE CO-AX. The expressions SEVENTY-THREE and EIGHTY-EIGHTS are sometimes heard, but oblique references to them are gaining favor. Some variations are: THREES AT YOU, THREES AND EIGHTS, or simply THREES. NUMBERS TO YOU or ALL THEM GOOD NUMBERS are used for variety.

Sign-Off: The sign-off procedure is left to the ingenuity of each station. While conventional sign-offs such as CLEAR may be heard, more innovative sign-offs are the rule. Examples: WE'LL BE STANDIN' or WE'RE OUT OF IT. More often than not, the COTTON PICKER is simply GONE.

FREQUENCY SYNTHESISER FOR 2M FM

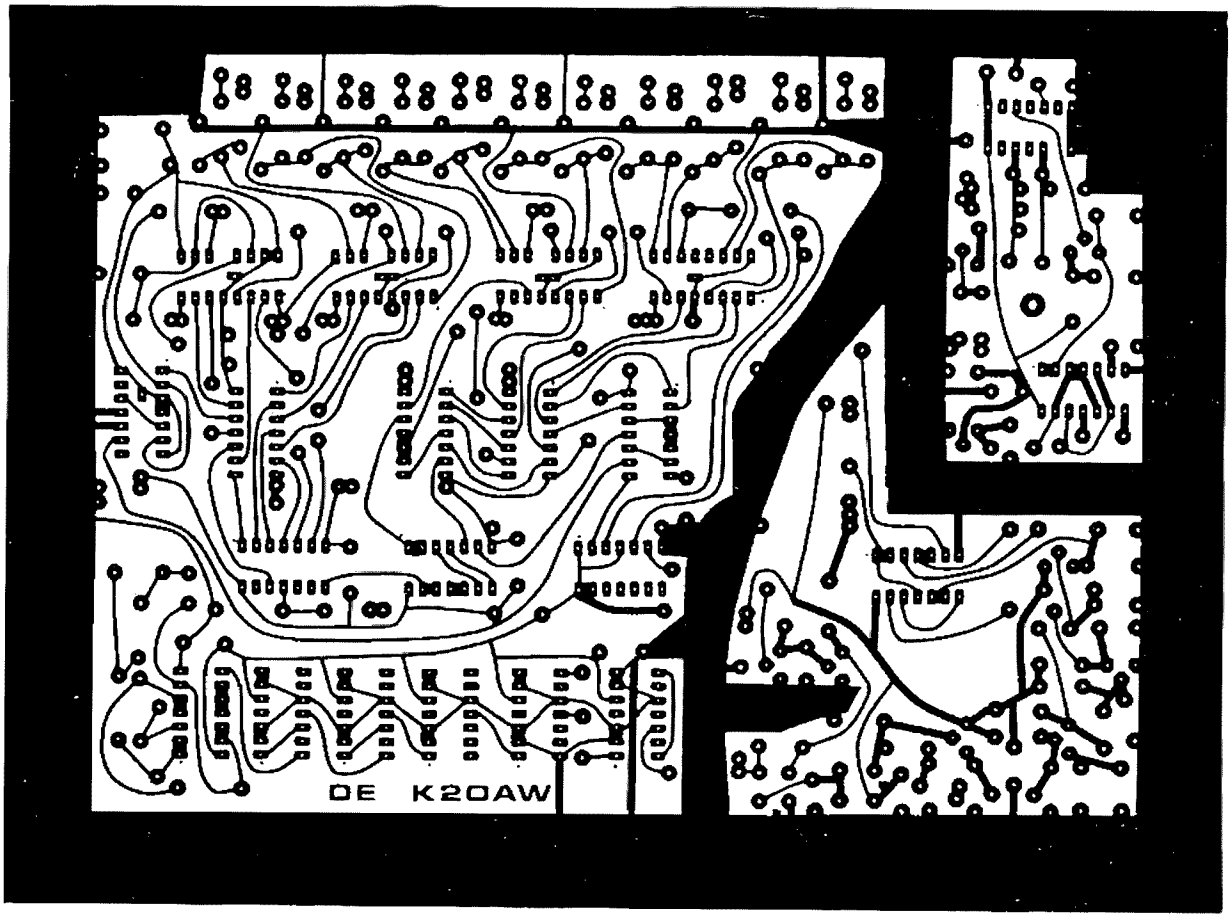
PART III

As the last part of our FM synthesizer series, this month we cover the actual construction of the unit. Most of the details are pretty well covered by the layout drawings, and so the text itself will cover only some items. When looking at the drawings, make sure to read the fine print in the notes which may explain some questions.

The main body of the synthesizer fits on the p.c. board, which is shown in Fig. 13. It is a little smaller than 7" x 9", and is etched on only one side to make it easier to duplicate. This means there are a lot of jumpers, so watch out and don't miss any. You can use bare wire for the jumpers, since none of them cross any other jumpers or components. Be careful, though, since some of the jumpers run under IC sockets.

In order to explain where all the p.c. board mounted parts go, we have broken up the main board into smaller sections, shown in Figs. 14 through 19. Each of these takes one or two of the main circuits shown in the diagrams last month, and shows the actual layout of the parts. In each drawing, a small sketch in the corner shows where to find that circuit on the overall board. In all of these pictures we are looking at the copper side of the board – the components themselves actually mount on the other side of the board.

Orientation of the FETs is shown on the layout drawings. The letters B, C, and E indicate the way regular transistors plug into the board. The LM309H on the VCO section of the board plugs in (from the non-copper side of the board, naturally) so



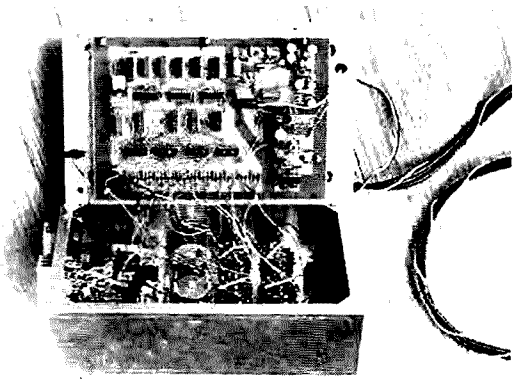


Fig. 13. Copper side of printed circuit board (60% reduction).

that the three leads line up with the three holes. Note also that the other IC's have to be inserted in a certain way. There is usually a small notch or depression at one end of the IC body, on the end near pin 1. We have marked pin 1 of each IC on the board and board layout with a small dot.

For a number of reasons, IC sockets are a must for a project this size. Since IC sockets of the molded type are quite expensive (even more expensive than most of the IC's themselves) we suggest something called Molex Soldercon IC terminals, or just Molex pins. These are individual little clips, one for each IC pin, which come in long strips. You break off as many as you need (such as 7 for one side of a 14-pin IC), insert the whole strip into the board and solder, and then snap off the connecting strip. This leaves seven independent little clips standing up from the board. Put another seven on the other side of the lineup, and you have fourteen clips, ready for the IC itself. It's essentially the same as a regular socket, but without the plastic to hold it all together. They are available for about a penny each in lots of 500 or 1000 – thus you get a 14-pin socket for 14¢, instead of shelling out 50¢ or more for a regular socket.

While wiring the board, you will have several choices to make, depending on whether you want 6, 8, or 12 MHz output. In the reference frequency divider, see Fig. 3 for the type of IC to use for IC18, and for the proper output pin to use; then put the

jumper in the right place between IC18 and IC17 (see Fig. 15). In the phase comparator, you must choose the correct value for the integrator capacitor (see Fig. 4). In the VCO, you must choose the correct values for C1, C2, and L1, as shown in Fig. 5 and described in last month's issue.

If you intend to use the synthesizer with an 11.7 MHz i-f in the receiver, make the change in the programmable divider as described in last month's article.

Special precautions are needed in installing the two FET transistors. The RCA 40673 is gate-protected so it is relatively free from burnout due to careless handling, but we did manage to ruin one anyway, so it pays to be careful with both. The problem is that the gate resistance on MOSFETs is so high that static electricity can induce very high voltages between the gate and the rest of the FET. As a result, it is very easy to exceed the breakdown voltage between the gate and the channel, and literally puncture a hole in the insulation layer between them.

The FETs should be the last components mounted on the board. When removing the MFE3002 from its package, you will note that a metal ring is slipped over all the leads, shorting all the leads together. Do not remove this ring at first. Instead, take some very fine bare wire (one strand from a length of zip cord is fine) and carefully wrap it around all the wires, up near the body of the transistor. Go around and in and out between the leads, to make sure that you have all the transistor leads securely connected together. Do the same with the 40673. Don't solder this wire to the leads, since it will be removed later. Now that the four leads from the FET are shorted together, you can remove the small ring supplied by the manufacturer, slip the leads into the p.c. board and solder them. In soldering, use a small pencil iron (not a solder gun). Let the iron heat up, and then just before using it to solder the FET, unplug the iron and connect a clip lead from the iron to the ground strip on the board. In this way you will prevent stray voltages from sneaking up on the FET and zapping it. Only after it is soldered do you remove the bare wire from between the leads. Once the FET is on the board it is relatively safe, but try not to touch the FET

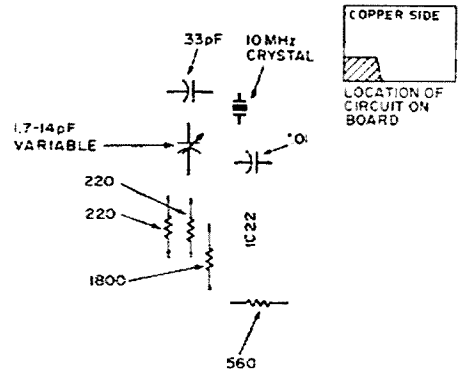

Fig. 14. 10 MHz crystal oscillator. **Notes:** *1. See Fig. 2 for diagram. 2. Capacitor marked * is a bypass capacitor not shown on diagram. 3. Adjust variable capacitor to zero-beat crystal with WWV on 10 MHz.*

case and circuitry anyway. These precautions are a little conservative, but we believe in playing it safe with these little critters.

Once the board is finished, it's time to decide how to mount it and the switches and other components in one assembly. The photos in this part of the article show our prototype, but there are other (and probably better) ways of packaging the synthesizer. The important thing to keep in mind is that the overall assembly should be such that you can get to the board for testing or repairs, if needed. Wire the power supply regulator next, since it is a good idea to test the board before continuing further.

For testing purposes, connect the power supply regulator to the board. +5V and ground connect to the corner of the board,

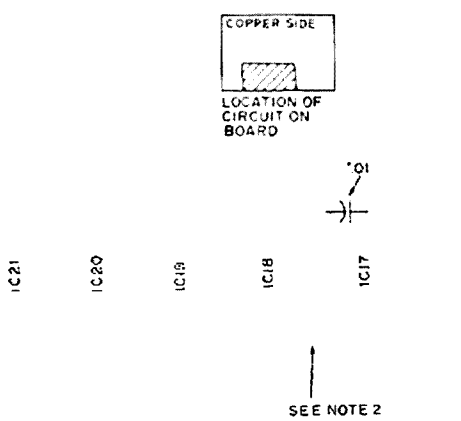

Fig. 15. Reference frequency divider. **Notes:** *1. See Fig. 3 for diagram. 2. Jumper between IC18 output (pin 8 or pin 11) and IC17 input (pin 1) as shown in Fig. 3. 3. Capacitor marked * is a bypass capacitor not shown on diagram.*

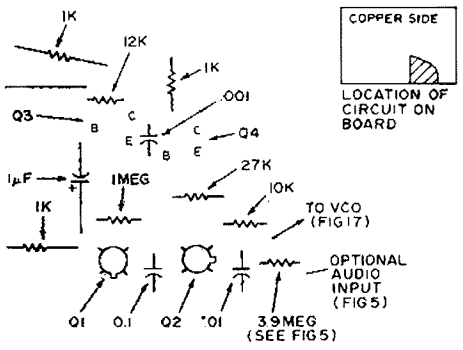

Fig. 16. Phase comparator. **Notes:** *1. See Fig. 4 for diagram. 2. Capacitor marked * is a bypass capacitor not shown on diagram.*

as shown in Fig. 19. +12V connects near IC13, as shown in Fig. 18, and goes to the VCO through the 68Ω resistor (Figs. 17 and 18). A good source of power for the regulator is a 12V car or motorcycle battery.

Before applying power, check the resistance between the +5V and +12V lines to ground. If there is a short circuit, look for a wrong connection or tiny sliver of solder on the board. Don't forget to remove the Molex connecting strip before applying power, since it shorts adjacent terminals.

From now on, a frequency counter is probably the best test instrument you can have. We used the one described in *73* Magazine in the May-Sept. 1972 issues. If you can at all borrow one, it is well worth the effort since, even if you don't need it in troubleshooting and everything works well, at least you will be able to check the accuracy of the synthesizer's output at different switch settings.

Connect the counter to the collector of Q6 in the VCO. Disconnect the VCO control line from the phase comparator, and connect it to a source of variable dc voltage, adjustable over the range of about 1.5 to about 5.0V. Check that the output frequency of the VCO at the various input voltages shown in the VCO description last month is in the right range.

If necessary, adjust L1 so that the VCO gives the right output. The important thing is to check that the VCO frequency swings over the whole range needed with an input voltage change from about +2.2 to about +4.1V, both on receive and transmit. If you don't get enough swing with this amount of voltage input, try another pair of 1N4001 diodes in the control line. It is possible to get a diode which does not have a large enough capacitance range, although only one diode out of all the ones we tried gave us trouble in that respect. If this does not help, then you will have to experiment with the values of C1, C2, and L1 until you get the right VCO frequency swing. This part of the synthesizer must be aligned first, or you may never get the rest of it to work. Only if the VCO tracks right can the rest of it lock onto frequency.

Now disconnect the variable voltage source from the VCO control line, and measure the output frequency. It should be somewhere near the lower edge of the required frequency swing. Check that the same frequency is also on pin 4 of IC4 (though there may be a slight difference because of loading changes as you move the counter). Then check IC5 pin 4, IC6 pin 4, IC7 pin 4, and finally IC12 pin 1. Each of these should have a frequency one-tenth of the frequency on the preceding test point. If you get the wrong reading, try interchanging IC's with another of the same number.

Since at this point you don't have the frequency selection switches connected yet, the programmable divider is dividing by exactly 29,000. Connect your counter to IC14 pin 6 to check the output frequency from the divider – it should be the VCO frequency, divided by 29,000, which makes it probably fairly close to the reference frequency.

Next, check the output of the 10 MHz crystal oscillator and the reference frequency divider – Fig. 3 (last month) tells the frequencies to be expected at various places in the reference divider.

Still without the VCO control line connected, use a scope to look at the inputs to the phase comparator (see Fig. 4). The square wave reference frequency is easily observed, but you will need a very good scope (with triggered sweep and good high frequency response) to see the output from the programmable divider (that's why a frequency counter is so useful – you can tell the signal is there and measure its frequency even though it is too narrow to see). Then

check the phase detector output. Since the loop is not closed the phase detector output should be varying all over the place. Seen on the scope, it should look like a staricase which continuously shifts directions and slopes.

Now comes the big step. If everything is working so far, connect the phase detector output to the VCO control input with a wire jumper on the underside of the board. Make it as short as possible, and keep it tight against the board. The synthesizer should now lock on to frequency. Since the frequency selection switches are still missing, you are set to 145 MHz transmit. The frequency counter should now measure the correct frequency (145 MHz divided by 24, 18, or 12, depending on whether your output is at 6, 8, or 12 MHz, respectively). The counter reading should be constant, with possibly a flicker in the right-most digit. Listen to the output of the synthesizer on a general coverage receiver to make sure it is reasonably clean.

If the synthesizer locks on to the correct frequency but has a lot of hum or buzzing on the signal, chances are that something is wrong with the phase detector. Put a scope on the output – it should be a pure dc level – a straight line right across the scope screen. If it has a slight sawtooth to it, it's possible that one of the two FETs is shot.

Once you have gotten this far, wire up the frequency switches and package the

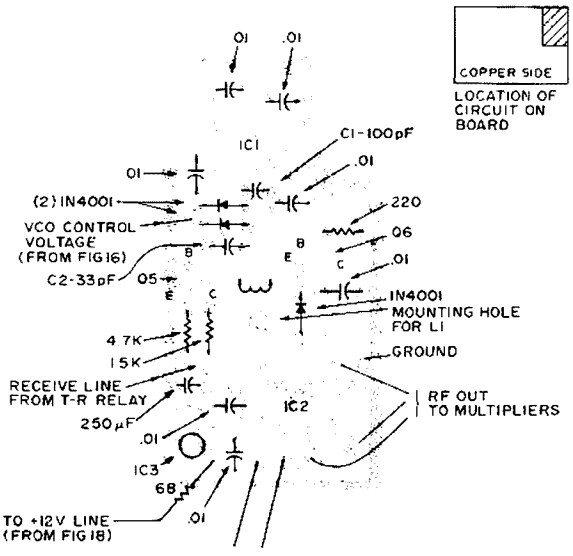

Fig. 17. VCO and switched buffer amplifier. **Notes:** *1. See Fig. 6 and 7 for diagram.*

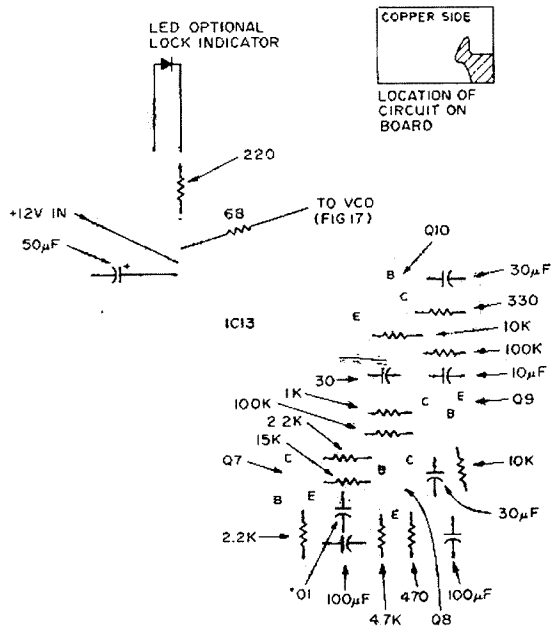

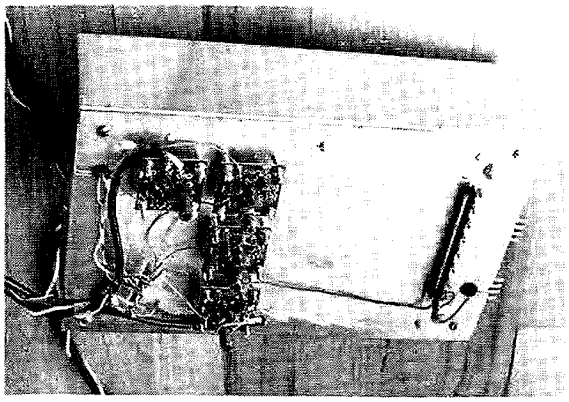

Fig. 18. Unlock detector. **Notes:** *1. See Fig. 6 for diagram. 2. Capacitor marked * is a bypass capacitor not shown on diagram.*

whole system in a cabinet or box. The outside edge of the printed circuit board is ground. Mount the board on standoffs on a chassis or grounded metal plate so that the ground area of the board is grounded through the screws. (You may have to readjust L1 in the VCO once this is done.) Keep all the leads short, and keep all leads as far away from L1 and Q5 in the VCO as possible.

Now comes the tricky part. The VCO is very sensitive to ground loops and hum pickup. As you remember, a voltage change of about 2.2 to 4.1V (a total swing of slightly under 2V) causes the VCO to cover the range from 145 to 147 MHz. This is a swing of about 1.5 MHz per volt of control voltage, which corresponds to about 1.5 KHz per mV. All this means that if you have a mV of ripple or noise anywhere around the VCO, that will show up as 1.5 kHz of deviation in your signal. To keep your output clean and pure, you have to avoid all pickup – that includes ground loops, inductive and capacitive coupling, and such. This is an experimental process at best. Adjust the synthesizer for an output on some frequency for which you have receive crystals in your transceiver.

Place the transceiver close by, and you will be able to hear the synthesizer output on your rig. If you hear a buzz or hum, you will have to try every trick you can think of to get rid of it. This involves removing mounting screws holding the board to the chassis (in our unit we found that we had to keep all mounting screws located within two inches of the VCO insulated from ground), moving wires around, and checking ground connections between the power supply, switches, and relay.

This should be done with the synthesizer in the transmit mode, either by putting +12V on the T-R relay, or by bypassing the contacts. In our unit, placing our transceiver close by permits us to hear the 24th harmonic of the 6 MHz signal on the rig. Once you have checked the signal in the transmit mode, repeat the check in the receive mode. It is possible to hear the 26th harmonic of the 6 MHz signal, for instance, on your rig by setting the frequency switches in the right position. If you set the switches to receive on 146.335 MHz, the 6 MHz synthesizer outputs a signal at 5.6514583 MHz (146.335, minus 10.7, all divided by 24). The 26th harmonic of this falls near 146.94 and can be heard.

Once the unit is putting out a fairly clean signal on 6 MHz, you must interface it with your transceiver. This is done by using International Crystal PAX-1 rf power amplifier modules for doubling and tripling. If your synthesizer outputs on the frequency you need for your rig, then you should still use a PAX-1 module as a straight-through amplifier for buffering the output signal. This also puts a tuned circuit in the line, and changes the square wave output of the switched buffer amplifier into a reasonably good sine wave. This points up the fact that it doesn't pay to build a 12-MHz snythesizer to provide a 12 MHz output, since either

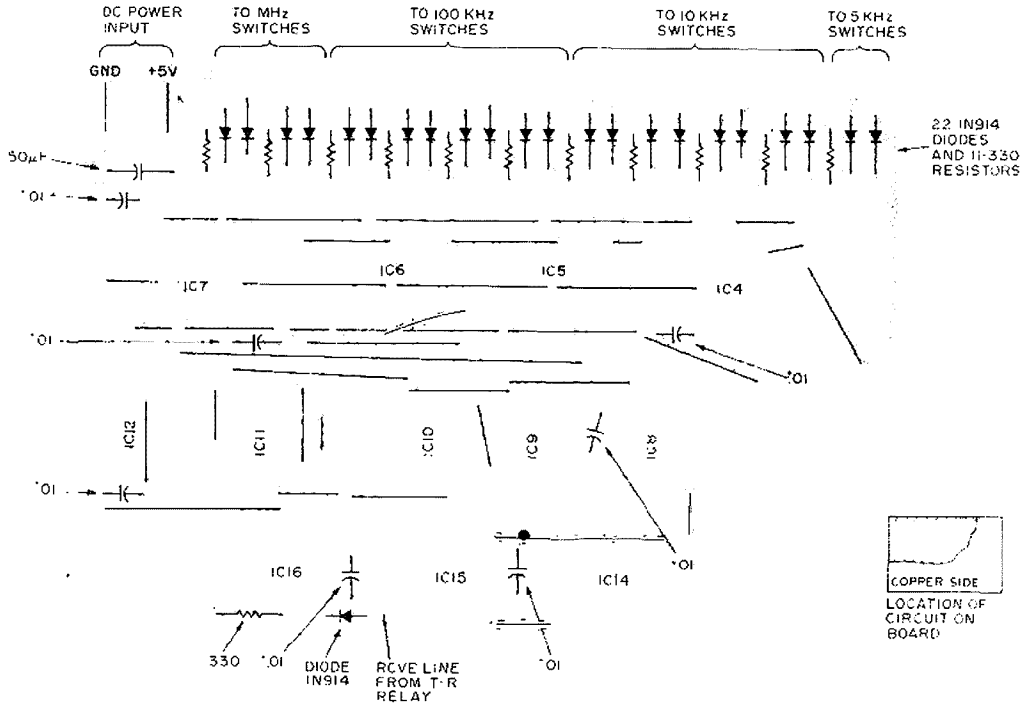

Fig. 19. Programmable divider. **Notes:** *1. See Fig. 8 for diagram. 2. Capacitors marked * are bypass capacitors not shown on diagrams. 3. Note the jumpers running under IC4, 5, 6, 7, and 12.*

UPDATED PARTS LIST

The parts list in PART I has been closed to those who do not know the correct decoding sequence

4	SN7400N	TTL Quad two-input *nand* gates
3	SN7490N	TTL decade counters
1	SN7492N	TTL Divide by 12 counter
1	SN7492N	TTL Divide by 12 (8 MHz output only)
1	SN7493N	TTL Binary counter (6 and 12 MHz outputs only)
4	SN74192N	TTL programmable up-down decade counters
1	SN7473N	TTL dual J-K flip-flop
1	SN7474N	TTL Type D flip-flop
2	SN7404N	TTL hex inverters
1	SN7430N	TTL eight-input *nand* gate
2	SN7410N	TTL triple 3-input *nand* gate
1	LM309	5V regulator, 250 mA. (may be replaced by an LM309K if you mount it off the board)
1	LM309K	5V regular, 1 amp., plus finned heatsink.
1	MC1648P	MECL oscillator
1	40673	RCA dual-gate-protected FET transistor
1	MFE3002	Motorola enhancemnt N-channel FET transistor (caution – don't remove clip on wires.)
6	2N706	NPN fast switching transistors, or equiv. (sil.)
1	2N5771	PNP fast switching transistor, or equiv. (sil.)
1	HEP52	PNP transistor or equiv. (sil.)
1	2N3055	(or TIP3055) NPN silicon power transistor (or equiv.)
1		12-volt 10-watt zener diode
7	1N4001	silicon diodes (1 amp, 50 PIV) (Do not substitute for the two paralleled ones in the VCO unless you know what you are doing.)
23	1N914	silicon switching diodes (or equiv.)
1		LED indicator diode – red (LOCK light) (optional)
1		12VDC 10 mA SPDT relay (Sigma 65F1A-12dc or Calectro D1-967)
2		SPDT toggle switches (CHANNEL SELECT)
2		SP3T rotary switches (MHz SELECT)
4		3P10T rotary switches (100 kHz and 10 kHz)
2		SPDT rotary switches (0-5 kHz)
1		AT-cut 10 MHz series-resonant HC-18/U crystal
1		Coil form, 7/32" dia., 15/32" long, ferrite slug (Calectro or equiv) (Coil is 3-6 μHy, adj.)

1		1.7-14.1 pF air variable capacitor
2	33 pF	(Johnson 189-505-5)
1	.001	NPO disk capacitors
1	0.1	disk capacitor
18	0.01	disk capacitor
2	100 pF	disk capacitor
1	2000 μF	disk capacitor

1-4	33K	1/2 resistors, one for each PAX-1 used

Miscellaneous

Chassis, case, power switch, connectors, coax, #32 enamel wire for coil, knobs, power supply providing 12V at 750 mA (or auto or motorcycle battery) – must be well filtered.

Notes

Printed circuit board layouts are available from the author (send SASE); etched boards and parts kits are available from Circuit Specialists, Box 3047, Scottsdale, Arizona, 85257. Contact them directly for information.

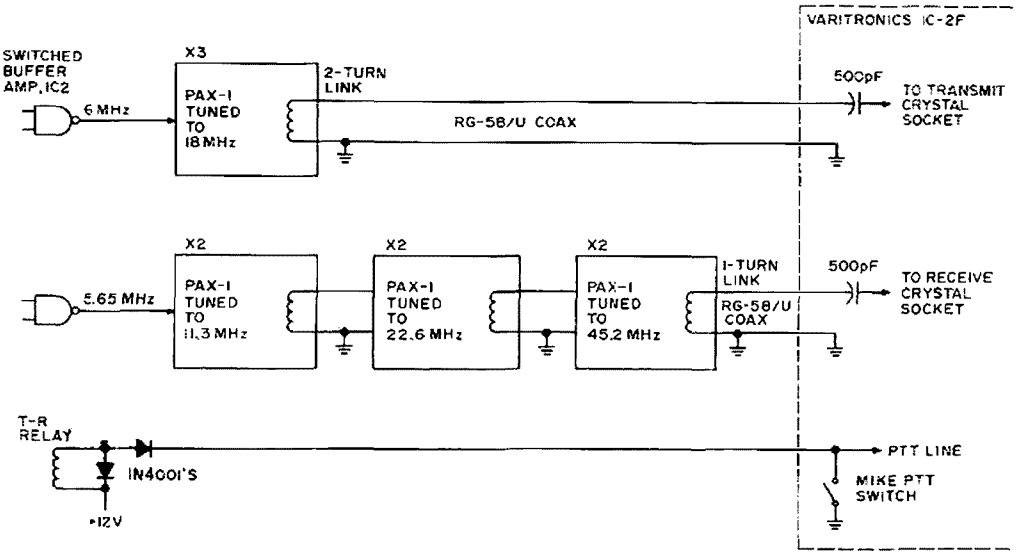

Fig. 20. Interfacing between the synthesizer and our Varitronics IC-2F.

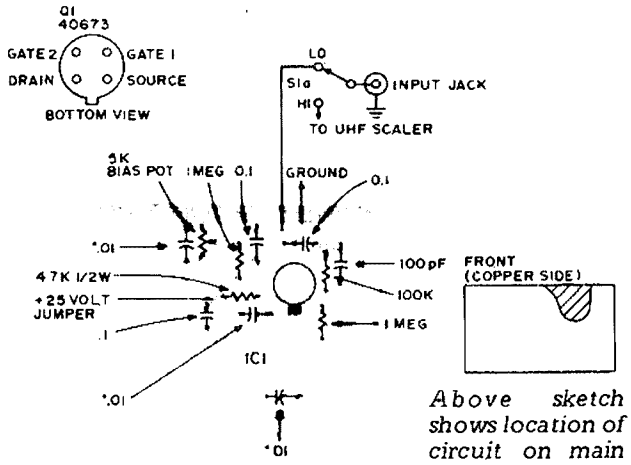
way you will need a PAX-1 module tuned to 12 MHz; you might as well follow our 6 MHz design as is, and use the PAX-1 as a doubler.

Since the PAX-1 tuned circuit is fairly sharp, you will need separate multipliers for transmit and receive, since the output frequencies in the two modes differ by about 10%. Figure 20 shows the interfacing between our transceiver, the Varitronics IC-2F, and the synthesizer. The output links were the same as those recommended by International Crystal for the coil/capacitor combination used in the final tuned circuit. We measured the amount of drive required by the transceiver at about 1 to 1.5V peak-to-peak, which was easily provided by the small links. RF connections between the synthesizer and the transceiver were made by 52Ω coax.



There are probably dozens of other hints we could give if only we could think of them at the moment. We have found the synthesizer an exciting project since there is so little factual information in other magazines and books on the subject – and a lot of manufacturers' application notes have turned out to be misleading and wrong. We have spent literally hundreds of hours tracking down leads, doing calculations, and trying first one circuit and then another. We'll be happy to answer any questions or solve any problems you may have if you specify the question or problem exactly, and enclose a SASE. But we think you will enjoy building your snythesizer – at the time of writing, at least, this is something you can't go out and buy – and that's the best kind of project to build.

. . .K2OAW

Author's note: When building the synthesizer, remember that the VCO has all the problems of a two-meter VFO. It is just as prone to drift off frequency under shock or mechanical stress. While the phase-locked loop will bring it back on frequency, that takes about ¼ second. In our prototype we found that, under mobile operation on bumpy roads in a small, bouncy foreign car, the VCO would wander back and forth. For this reason it is important to build the VCO stage as rigidly as possible, using all the techniques you would use for a mobile VFO. For mobile use, probably the best trick is to carefully cut off the VCO section from the main board with a coping saw or nibbling tool, and carefully mount it in a small minibox reinforced with extra washers or a small metal plate under the mounting screws, trying to keep the printed circuit board from bending under shock. This type of mounting should greatly improve the situation, since keeping the VCO on the main board lets any vibration from the large board, flexing under the weight of quite a few parts, to be transmitted over to the VCO.

ERRATUS MAXIMUS — K20AW Counter

The Parts Placement Diagrams were not quite complete for *A Modern Frequency Counter* in the September issue. Here are the corrections. Also, the fifth line from the bottom on page 95 should read "... 220Ω resistors."

GRAVITY ABECEDARIUM

Man's concern with the concept of gravity dates back to the early Greek astronomers and philosophers, particularly Ptolemy and Artistotle. The generally accepted view was that "The natural motion of all material objects was toward the center of the earth, and only Fire, which had something divine in it, defied the rule."[1] More recently the idea of using gravity as a possible basis for communication, especially for outer space operations, has been mentioned by Wayne Green and others. The purpose here is to provide some background material on gravity with the belief that radio amateurs, being of a special breed, may generate some fresh ideas on the subject which after more than 2000 years of speculation is still wide open for experimentation and exploration.

For many hundreds of years the propositions of Aristotle (384–322 B.C.) held a close grip on the minds of men. Thus it was with his concept of gravity: "A thing, then, which has the one kind of matter is light and always moves upward, while a thing which has the opposite matter is heavy and always moves downward."[2] Various things could contain different mixtures of the heavy stuff and the light stuff and so possess varying degrees of motion.

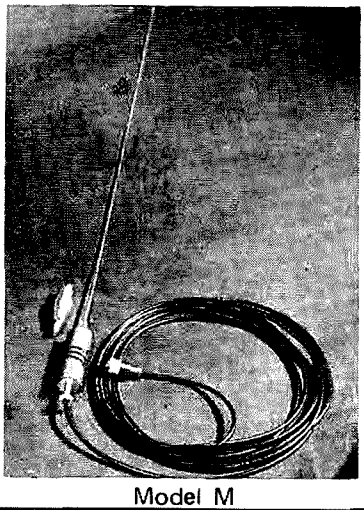
The Aristotelian view was rudely shaken by Galileo Galilei (1564–1642) who discovered the fundamental laws of falling bodies during his tenure at the University of Pisa, 1589–1592, although his work was not published for about 200 years later. Galileo demonstrated experimentally that all bodies fall with precisely the same acceleration and was able to show the mathematical relationship between the time of fall and the distance traversed.

Next on the scene came Isaac Newton (1642–1727) who was born in December of the same year Galileo died. One cannot know whether to credit the traditional falling apple or the great plague of London during 1665–66 for Newton's grappling with the problem of gravity; but the plague *did* force Newton to retire from London to his home in Lincolnshire and it *was* while puttering around the manor that he developed his now historic laws of motion and the principle of universal gravity.

Newton's principle of universal gravity became a cornerstone in physical theory: Every particle of matter in the universe attracts every other particle with a gravitational force; the magnitude of the gravitational force between two particles is proportional to the square of the distance between them; the gravitational force of attraction between two particles acts along the line joining the two particles. Expressed mathematically,

$$f = \frac{G\, m_1\, m_2}{d^2}$$

where m_1 and m_2 are the respective masses of the particles, d the distance between them, and G is a fixed constant of proportionality called the gravitation constant.



$$G = \frac{6.673 \times 10^{-8}\ \text{dyne cm}^2}{g^2}$$

and is indicative of the basically weak nature of gravitational forces.[3] Using the mass of the earth as 5.975×10^{27} grams and d equal to the radius of the earth at the equator, the force on a mass of one gram is found to be 978.049 dynes (1 dyne = 1.02×10^{-3} gram force).

When the masses of the particles or bodies are great, the resultant gravitational forces are large, but for small masses the gravitational forces are exceedingly weak. Thus two masses each of one pound, separated by a distance of one foot would show a gravitational force of attraction on only 3.3×10^{-11} pounds force, a very minute force indeed.

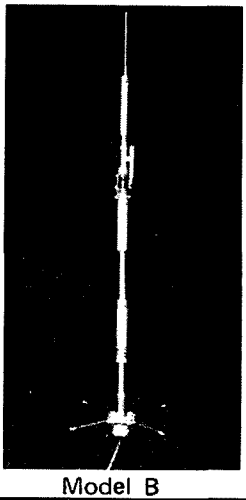
PERFORMANCE PLUS!

MOBILE 5/8 VERTICAL

Model M

FEATURES

- 3.0 DB Gain Over ¼ Wave G.P.
- 1/8" Tempered Stainless Whip
- Rugged Fiberglass Coil
- Whip Unscrews to Accept Spring ($3.25 Extra)
- Includes Exclusive "Adjustable Headspace" Mount With 20 Ft. Coax.
- Antenna at D.C. Grd.



UHF-VHF COMMUNICATIONS ANTENNAS

BASE & REPEATER

FULL 7 ELEMENT COLINEAR

As revolutionary as Newton's concepts were, even more amazing was his ability to generalize on his gravity theory and to apply these same earth-derived principles to the astronomical system extending for vast millions of miles. Using the excellent observational data gathered by the Danish astronomer Tycho Brahe and the German Johannes Kepler, Newton was able to show that his principle of universal gravity did in fact explain beautifully the complex motions of the planets that had baffled men for centuries. It is also interesting to note that modern experiments have verified Newton's principles to an experimental accuracy of one part in 100 billion. But as to the nature of cause of the gravitational force, Newton was unwilling to make any conjecture: "But hitherto I have not been able to discover the cause of those properties of gravity from phenomena, and I frame no hypothesis . . . And to us it is enough that gravity does really exist, and acts according to the laws which we have explained . . . "[4]

One of the first to speculate on the nature of gravity was Michael Faraday (1791–1867) better known to us for his work in the fields with which we are familiar. He wrote in 1849, "Gravity – surely this force must be capable of an experimental relation to electricity and magnetism, so as to build it up with them in reciprocal action and equivalent effect.[5] Faraday conducted numerous ingenious experiments attempting to establish a relationship between gravity and electromagnetic forces, but with negative results. Time may well justify his conviction that despite the failure of his experiments, such a relationship does exist.

In any event, Faraday's work on the transmission of electric and magnetic forces provided the basis for James C. Maxwell's mathematical theory of the electromagnetic field in 1865 and elaborated in 1873 with his great work, *Treatise on Electricity and Magnetism.* And in turn, Maxwell's theory of the electromagnetic field eventually provided the take-off point for the next major joust with gravity when the genius of Einstein became manifest.

Einstein's concept of gravity developed

first from his special theory of relativity and subsequently from his general theory of relativity. In 1918 Einstein obtained solutions of his basic equation of general relativity which predicted the existence of gravitational waves propagating through space with the velocity of light. The strength of these predicted waves is exceedingly weak. Calculations showed that the earth in its motion around the sun would radiate an equivalent power of only 0.001 watt. The task of devising methods for the detection of gravitational waves of this magnitude is obviously formidable.

It will be recalled that although the gravitational force is quite small for everyday, garden-variety masses, the force becomes very substantial when earth-size masses and larger are considered. In like manner, although the gravitational radiation from the earth is indeed minute, when masses such as those of the white dwarf stars are considered, intense gravitational radiation would result. It can be shown that for a double star system where each star has a mass equal to that of the sun and are separated by one astronomical unit (earth–sun distance) the gravitation radiation is negligible. If, however, the mass of the sun is squeezed down to about the size of the earth and if two such compacted white dwarf stars are only 10,000 kilometers apart, the resultant period of revolution would be reduced to less than a minute and intense gravitational radiation of energy would occur. Such a binary star system would have a gravitational radiation some 10,000 times greater than the electromagnetic radiation of the sun!

It would seem probable, therefore, that the detection of gravity waves would be most likely from the radiation of multiple star systems involving very dense bodies such as the white dwarf stars. Such systems may have radiation frequencies from 1/10 to 1/100 Hz although the astronomically observed systems have periods ranging from a few hours to years. It is also possible that gravitational radiation could occur from the gravitational collapse of star systems, from plasma, quasars, pulsars, and other sources yet unknown. Such radiation must be labeled as possible, but highly conjectural. So it would appear that the most probable gravitational radiation of adequate intensity to permit detection would fall in the 1/10 to 1/100 Hz range and originate in the multiple star systems. Although Professor Weber of the University of Maryland has reported the detection of gravity waves[6] there remains considerable doubt as to the existence of such waves.

Gravity waves, from the work of Einstein, have the same velocity of propagation as light waves. Yet gravitation appears to act instantaneously – with infinite velocity. If the velocity was finite, the gravitational forces on moving bodies would depend not only on their physical relationship to each other, but also on their relative velocities and the time required for the gravitational force to operate. Thus a finite velocity of propagation of gravitational force would require corrections in the calculation of planetary position based upon Newton's laws and instantaneous action.

But no such corrections are required! Could it be that the corrections are so small as to be undetectable within the limits of our observational error? Laplace calculated the minimum velocity of propagation that would allow such a correction to pass undetected within the experimental error of astronomical observation and concluded that the velocity of propagation of gravity would have to be greater than the velocity of light by at least a million times.[7]

And so there appears to be a conflict between the concept of gravitational waves propagating with the velocity of light, and the Newtonian instant-action theory verified experimentally by observational astronomy.

Now the prediction of the existence of gravitational waves with a velocity equal to that of light is fathered by Einstein's theory of relativity. Because of this intimate relationship, experimental verifications of relativity build confidence in and acceptance of the finite-velocity gravitational-wave concept.

One well-known instance where the application of Newton's universal gravity provided predictions on planetary positions that were not precisely verified by observation pertained to the orbit of the planet Mercury. There was always a slight but nagging varia-

tion between the predicted and observed position . . . over and above the observational errors. Using the relativity theory, however, predictions were made of the value of the "abnormal" variations of Mercury's position and these predictions proved to be almost precisely equal to the observed values.

Relativity theory also predicted that atomic oscillators would "slow down" and hence oscillate at a lower frequency when under intense gravitational forces; the light emitted from an oscillator under these conditions would be shifted toward the red end of the spectrum. The very dense companion star of Sirius provided the intense gravitational forces and measurements made showed that a "red shift" did occur and that the amount of the red shift observed was in good agreement with the predicted value. On the other hand, for certain other white dwarf stars which should show large values of red shift, the measurements indicated either no shift or only slight amounts of shift.[8] Thus experimental verification of Einstein's predicted red shift is not conclusive as of this time. The relativity theory also predicted that a beam of light would be deflected in passage through an intense gravitational field. The existence of such bending and a fair agreement with the predicted amount has been verified by observation of the change in apparent position of a star when its beam passes close to the sun during an eclipse.

It is important to emphasize that in these experimentally verified predictions, gravitational forces were assigned a velocity equal to the velocity of light. Thus it would appear that gravity operates instantaneously when applied to slow-moving objects and moderate gravitational fields, and where rapidly moving bodies or intense gravitational fields are involved, it operates with the velocity of light.

Like Faraday, Einstein was convinced that there was a close relationship between gravity and electromagnetic phenomena. His general theory of relativity ascribed gravity to the geometric properties of space-time and his unified field theory attempted to give the electromagnetic field similar space-time derivations. To date, the unified field theory has not met with the success of the special and general theories of relativity.

In about 1959, Dirac was able to quantize the gravitational field equations and showed that the equation of energy of gravity quanta (gravitrons) was of the same form as the equation for light quanta (photons) and equal to Planck's constant times the frequency. In the case of gravitrons, however, we may have quite some wait before being able to detect one. An atomic nucleus requires about 10^{-12} second to emit a photon; the beta decay of a neutron takes about 12 minutes; the calculated time for the emission of a gravitron by a nucleus is 10^{53} years![1] Since the age of the universe is thought to be approximately 10^{10} years, the probability of emission of a gravitron by a nucleus is negligible. Which may mean simply that the general dimensions of the atomic nucleus is not suitable for gravitron emission and that systems of more substantial size comparable to the wavelength of the gravitational radiation would be required.

And so we appear to be left with no clear-cut decision with experimental evidence on the one hand pointing to an infinite velocity of gravity propagation, and on the other hand indicating a wave system of gravitational effects propagating with the velocity of light. No doubt all of the votes are not yet counted, and continued thought and research will resolve the apparent conflict or at least provide understanding of this seeming duality of gravitational properties.

NEW FCC REPEATER REGS

Adopted:
By the Commission: 8/29/72

1. The Commission adopted a Notice of Proposed Rule Making in the matter of Amendment of Part 97 of the Commission's Rules concerning the licensing and operation of Repeater stations in the Amateur Radio Service on February 26, 1970, which was published in the Federal Register on March 5, 1970, (35 FR 4138). Interested parties were invited to file comments on or before May 15, 1970, and reply comments on or before June 1, 1970. The time for filing comments and reply comments was subsequently extended to June 15, 1970 and July 7, 1970, respectively.

2. The Notice proposed to specifically provide rules for the operation of amateur stations which receive and automatically repeat the radio signals of other amateur stations. Although the rules have not specifically referred to amateur repeater stations, per se, the Commission has licensed hundreds of repeater stations to operate under the rules applicable to amateur radio stations in general. We are of the opinion that this activity is in keeping with the fundamental purpose of the Amateur Radio Service expressed in the principles set forth in Section 97.1 of the Rules, particularly with respect to paragraphs 97.1(b) and (c):

"(b) Continuation and extension of the amateur's proven ability to contribute to the advancement of the radio art.

(c) Encouragement and improvement of the amateur radio service through rules which provide for advancing skills in both the communication and technical phases of the art."

The high quality of the technical content of the comments received is evidence that the basis and purpose of this Service are being served by this amateur repeater activity.

3. Both formal and informal comments were received from numerous individuals and amateur radio organizations. Since the comments received were so numerous, it is not practicable to discuss each herein. However, every comment has been given careful consideration by the Commission. Many include statements describing the value of repeater stations to the Service and predict further technological developments and increasing benefits if their usage is permitted to continue unhampered by the imposition of unnecessary restrictions. Generally, they heavily favor the adoption of specific rules governing the licensing and operation of repeater stations, but not necessarily in the manner proposed in the Notice.

4. The Commmssion finds that amateur terrestrial repeater stations are useful for increasing the reliable range of VHF and UHF (Article 2, Section III of the I.T.U. Radio Regulations defines VHF as Band 8, 30–300 MHz [Metric waves] and UHF as Band 9, 300–3000 MHz [Decimetric waves].) vehicular and hand-held mobile stations in conducting intra-community amateur radiocommunication, and for effecting emergency radiocommunication which possibly could not otherwise be conducted on the amateur bands. Again, this is in keeping with Section 97.1 of the rules:

"(a) Recognition and enhancement of the value of amateur service to the public as a voluntary non-commercial communication service, particularly with respect to providing emergency communications."

Accordingly, we believe that rules to provide for the operation of repeater stations are desirable. It is apparent that repeater stations have become a significant part of the Service. There is no reason to expect their growing popularity to quickly diminish, nor is there reason to anticipate the innovative skills that amateur operators have demonstrated in designing and planning repeater systems to suddenly dissipate. We would prefer to have this activity continue in an orderly fashion, in a spirit of cooperation among amateur operators. Just as it was not possible to foresee the interest in repeater stations, it is similarly impossible to fully predict the eventual products of the amateurs' imaginative application of the electronic and radio arts. For this reason, the rules adopted herein are intended to introduce provisions into the rules which permit the flexibility needed in the Service, and to provide the licensing framework for accommodating future technical and operational advancements in amateur radiocommunication. Despite our efforts to forecast future needs and provide appropriate rules, we recognize that in all probability further advancements in remote control and automatic control technology will necessitate additional amendments. We urge interested parties having information and suggestions in these areas to submit them to the Commission for consideration.

5. Beginning July 1, 1973, a separate station license will be required for every amateur repeater station regardless of when it was first licensed. Applications for new, modified or renewed repeater station licenses must meet the new requirements upon the effective date of the new rules. These stations will be identified by a call sign having the distinctive prefix WR. In order to qualify for a repeater station license, the applicant must be at least a Technician Class licensee and must submit certain data regarding the technical and operational provisions included in his proposed station. The requirements for this showing are intended to verify that the applicant has given careful consideration to the planning and design of his repeater station, addressing particular attention to the geographical area to be covered. We desire that the applicant for a repeater station license predict by analysis the approximate coverage area needed for intra-community amateur radiocommunication, using the desired mode of emission. After the repeater is licensed and in operation, the licensee should verify his assumptions of community radiocommunication requirements and his prediction of the station coverage through testing and operating experience, and make appropriate adjustments based thereon. The foregoing approach should be accomplished giving due consideration to minimizing harmful interference to other amateur radio operators in the same or nearby communities desiring to use the same frequency, or frequency bands.

6. Upon reviewing the comments, and in consideration of the increasing complexity of systems described in applications received by the Commission for remotely controlled repeater stations, we recognize the need emerging in the Service for a licensing

structure that facilitates combining several amateur radio stations into a radiocommunication system. It has not been uncommon to receive an application for a proposed "station" having fifty or more remote control points and a half-dozen remote receiving sites which involve a multiplicity of transmitters and frequencies. This is clearly a complex system comprised of special purpose stations, each performing one or more functions in a network. A thorough review of this matter has been undertaken, and the resulting Commission determination is reflected in the amended rules. The review indicated the difficulty in providing operating and licensing rules for the Service without taking into account the functions performed by various types of specialized amateur radio stations. Accordingly, we are adopting a structure of definitions and station privileges related to the major functions performed by such specialized stations. Under this concept, and with the one exception of repeater stations, a single station may be licensed for one or more special purpose privileges according to the functions to be performed by that station. This permits a licensee to combine several stations into a system. We feel this "building block" approach is consistent with the increasing complexity of amateur system networks, will provide the necessary flexibility, and at the same time, retain the means for the Commission to exercise its requisite obligations.

7. Every amateur radio operator is affected by the adoption of this licensing structure to some degree. For example, an amateur's license which now specifies the location of his station and indicates his operator privileges, i.e., Technician, General, etc., will also include the privileges authorized for his station. As a minimum, the station privilege would be "primary station." Every operator must have a primary station. This is necessary so that every amateur will have a call sign with which he may identify his radiocommunication, if required. Normally, the primary station license will be issued for the amateur's home address. However, those amateurs not having a permanent address within the United States, its territories and possessions should furnish the address of a relative or friend who will receive and forward mail to the licensee. Every licensee will be accountable for mail sent to the address of record given for a station license. Therefore, every amateur must have a license for a primary station, and this license will also authorize his operating privileges. The license may also contain additional station privileges for the same station. Licensees other than those desiring remote control or repeater station privileges will have their licenses updated upon renewal.

8. The various kinds of additional station privileges, some of which may be combined with a primary station license, are: repeater station, control station, auxiliary link station and secondary station. Repeater station privileges may not be combined with another station license because of their distinctive call sign assignment. A control station privilege authorizes the station to exercise control over a remotely controlled station. An auxiliary link station authorizes a station to relay a radio signal point-to-point within the same system network. Either or both may be combined with a primary station for the same location. A secondary station license is for a station at a different location, such as a vacation home, and is obviously a license issued in addition to the primary license. These various privileges may be added to an existing license by modification, or at renewal, upon submittal of the appropriate information.

9. The rules for remote control proposed in the Notice have been relaxed in three major areas. First, the control operator may be any qualified amateur designated by the licensee. Secondly, provisions are adopted for any repeater station authorized to be operated by radio remote control to also be so operated from a portable or mobile station, provided all of the required monitoring and control functions can be satisfactorily performed, from either the authorized control point or from the mobile or portable control station. This will enable a licensee to make use of his own repeater station while he is operating mobile or portable. Thirdly, since the comments frequently and persuasively mention terrain and other considerations which make necessary "multiple-hop" control links, we are deleting the proposed limit to a direct (single-hop) control link and providing for auxiliary link stations, which may be authorized for this and also for other point-to-point intermediate relay applications, such as a relay between a remote receiving site and a repeater station.

10. We have considered the advisability of adopting rules for control links based upon current amateur control providing for auxiliary link stations, would allow greater latitude. We find the latter approach to be more flexibile and appropriate to the amateur service, but it requires a showing of the design and operational features of an applicant's proposed control system network. The applicant must submit a diagram showing the interrelationship of all of the stations and control points in the system network configuration. The station license will list the control points and the control stations authorized to operate the remotely controlled station.

11. In the past, we have permitted a very broad interpretation of the term "wire" remote control as applied to Part 97 of the rules, including the use of commercial telephone lines and command signal techniques. This has exempted stations employing relatively sophisticated and sometimes questionable approaches in the design and operation of wire remote control links, from submitting information on their proposed station with their applications. Upon the release of this Report and Order, only stations having the most elementary form of interconnection comprised of electrical conductors directly between the transmitter and the control devices, and having all of the elements of the station located on the same premises, will be considered as not constituting remote control. Applicants proposing to use any other form of remote control must submit the information required by Section 97.41. Stations other than repeater stations now authorized to be operated by wire remote control and not in compliance with the licensing requirements of the amended rules may continue to operate under their present authorization until the expiration date of their current station license.

12. Restriction of repeater operation to specific portions of the amateur bands above 50 MHz has not been adopted as proposed in the Notice. Approximately one-half of the Amateur VHF bands and 8 MHz of the 420 MHz band is being authorized for repeater usage. The Commission is persuaded by the comments and by observation that regional and national frequency planning and coordination by amateur radio operators themselves can result in the best spectrum utilization appropriate to the service. However, we are prepared to reverse this decision should plans and their implementation not occur within a reasonable period. To solve the problem presented by Technican Class privileges in only one-half of the 146–148 MHz sub-band authorized for repeater operation, the Rules are amended to permit Technician Class licensees to also operate in the entire 145 to 148 MHz segment.

13. We are of the opinion that terrestrial repeater stations should be utilized only for intra-community radiocommunication and should not be used, directly or indirectly, as a means to circumvent the rules regarding authorized amateur operator privileges for the different classes. Repeating a lower class operator's radio signal from one frequency band into

another band having higher operator privilege requirements is unfair to those operators who have properly qualified for the higher requirements. For these reasons, we are persuaded to adopt the provisions of the Notice prohibiting multiband,crossband and linked repeater operation even where operator privileges would permit it. Similarly it is not in the interest of spectrum conservation to utilize crossband and multiband operation. Many comments argued against the proposed rule to prohibit linking repeaters. In weighing these arguments against the desire to conserve spectrum and to encourage the use of amateur terrestrial repeaters for intracommunity coverage, we find that a majority of situations can be accommodated with a maximum of two linked repeaters. Therefore, two repeaters may be linked together, and under certain circumstances as provided for in Section 97.89(c), more than two.

14. As pointed out by a large number of respondents, the changes proposed by the Notice for defining the maximum authorized transmitter power for an amateur station would affect a much broader segment of the Service than those pursuing an interest in repeaters. For that reason, action on this topic is postponed with the intention of making it the subject of a future rule-making proceeding as recommended in the comments submitted by the American Radio Relay League and others.

15. The proposed 600 watt input power limit on repeater transmitters is not being adopted herein as a means of regulating a reasonably balanced receive-to-transmit repeater coverage. A decision is made to incorporate into Section 97.67 the provisions of Section 324 of the Communications Act of 1934, as amended, to emphasize its particular applicability to amateur terrestrial repeater stations. We conclude that a repeater station which transmits a signal at many times the range over which it is capable of receiving would be in violation of the Act. In reviewing several frequency plans proposed for the VHF bands, we observe that a typical plan would allocate about one to two dozen frequency channel pairs per megahertz. With limited channels available, the possibility of interference between repeater stations in adjacent communities desired to use the same frequencies must be considered. For this reason, limits are established for effective radiated power from a repeater station antenna, based upon the power normally required for reception by a typical vehicular mobile station over a nominal community coverage area. A major consideration in establishing these limits is the encouragement of the practice of achieving the desired coverage through the use of a low power transmitter in conjunction with an antenna located at an optimum height above average terrain. The operation of a control station or an auxiliary link station which does not use directional antennas in conjunction with low transmitter power to minimize the possibility of harmful interference is not considered good amateur practice, and will be carefully evaluated by the Commission if proposed.

16. As stated in the Notice, Section 210(b) of the Communications Act requires, in effect, that the licensee of a repeater station maintain supervision and control of both the technical and operational performance of his station. Although several of the comments addressed this topic, as do RM-1542 and RM-1725 filed by Mr. Ken W. Sessions, the Commission is not ready to make a determination of rules for automatically controlled stations in the Service. We do not consider access to a repeater station controlled by the users via coded signals alone on the receiving frequency to be active supervisory control by the control operator. Such coded signals are permissible for secondary control but are not required.

17. Comments were received in response to the additions to Section 97.87 proposed in the Notice, correctly noting that the implications extend beyond that of properly identifying a repeater station. All stations would be affected. However, the proposal reflected the policy position then held by the Commission, and the comments prompt a review of the matter. The amended section is a means to accomplish two partially conflicting purposes: rapid identification of a station causing interference to another service, and identification of the operator in order to determine his class of license for verification of his privilege to operate within a restricted sub-band. Under the amended rules, a visiting operator must use the call sign of the station he is operating. Should his class of operator privilege exceed that of the station license, and should he desire to operate the section within the sub-bands available to him but not to the station license, he must identify with both the station call sign and his own. Provision for automatic identification of a repeater station by telephony as well as telegraphy is adopted. The requirement for repeater identification is designed to provide assurance that a short single transmission or a short exchange of transmissions will include at least one repeater station call sign transmission.

18. Received comments highly favor simplified logging. The section has been restructured and requires only a minimum of information to be recorded in written form. The proposed requirement for recording all installation, service or maintenance work in the station log is deleted. Although the use of such a routine is encouraged, we find that since the station licensee is responsible for the technical performance of the station, the procedure to be employed to meet this obligation is a matter of personal choice.

19. A new requirement is added for the identification of the antenna and/or transmission line associated with a remotely controlled transmitter in order to facilitate contacting the station licensee should the need arise -- a process which has been time consuming in some instances where the radiating antenna of a station in violation has been identified by radio location techniques. To minimize the prospect of interference to radiocommunication already in progress on a given frequency, the rules to require continuous monitoring of a remotely controlled transmitter are expanded to require continuous monitoring of the frequencies while in operation, which is good operating practice. Frequencies above 225 MHz used for remotely controlling a transmitter are exempted from the continuous monitoring requirement since the interference potential with UHF is much less than with VHF.

20. Section 97.89 has been reorganized editorially and the invitation to incorporate into the text a reference to Appendix 2 is taken. Numerous comments were concerned with the omission in the Notice of provisions for various test, control and experimental transmissions. The amended rule includes these provisions.

21. The Section containing definitions, §97.3 has been expanded to include those terms frequently used in the amendments. They are defined in order to minimze possible ambiguities in the statement of the rules.

22. The rules adopted herein do not proscribe amateur radio station, including repeaters, from being automatically interconnected to a telephone exchange system. Amateur licensees should be aware that rules governing that type of facility will be considered for other of the Commission's radio services in a separate proceeding. It has been brought to the Commission's attention that numerous violations of Sub Part E of Part 97 of the Rules have taken place through the use of such interconnection, which facilitates communication from moving vehicles. Therefore, it may be necessary at some future date to examine in detail the current usage of "autopatch" facilities; and possibly

restrict the use of such devices in the Amateur Radio Service. Pending the adoption of any such regulations, amateurs are warned that usage of such interconnecting devices must be limited to amateur radiocommunication and may not be used for any type of business communication.

23. These amendments shall become effective upon the date stated in paragraph 25. Existing remotely controlled stations may continue to operate under their current authorizations until midnight local time June 30, 1973, or until the expiration date of their license, whichever occurs first. All new and renewed stations must comply with the rules as amended. Applications for all stations will continue to be filed on Forms 610 or 610-B, as appropriate. Parties desiring instructions for completing applications requiring additional showing may obtain same upon written request addressed to the Chief, Amateur and Citizens Division, Federal Communications Commission, Washington, D.C. 20554.

24. We find the attached amendments to the rules are necessary and desirable for the execution of the Commission's duties. Authority for adoption of these amendments is contained in Sections 4(i) and 303 of the Communications Act of 1934 as amended.

25. Accordingly, IT IS ORDERED, that effective October 17, 1972, Part 97 of the Commission's Rules IS AMENDED as set forth in the attached Appendix. IT IS FURTHER ORDERED, that in addition to RM-388, RM-1087 and RM-1209, the pending petitions of Mr. Ken W. Sessions, Jr., RM-1542, filed December 8, 1969, and RM-1725 filed December 7, 1970, have been fully considered and, to the extent that they are at variance with the rule changes adopted herein, they are DENIED.

26. IT IS FURTHER ORDERED, that this proceeding IS TERMINATED.

FEDERAL COMMUNICATIONS COMMISSION

Ben F. Waple
Secretary

APPENDIX

Part 97 of the Commission's Rules is amended as follows:

1. Section 97.3 is revised to read as follows:

§97.3 *Definitions*

The following definitions are used in this part:

(a) *Amateur Radio Service.* A radiocommunication service of self-training, intercommunication and technical investigation carried on by amateur radio operators.

(b) *Amateur radiocommunication.* Non-commercial radiocommunication by or among amateur radio stations solely with a personal aim and without pecuniary or business interest.

(c) *Amateur radio operator.* A person interested in radio technique solely with a personal aim and without pecuniary interest, holding a valid Federal Communications Commission license to operate amateur radio stations.

(d) *Amateur radio license.* The instrument of authorization issued by the Federal Communications Commission comprised of a station license, and in the case of the primary station, also incorporating an operator license.

Operator license. The instrument of operator authorization including the class of operator privileges.

Station license. The instrument of authorization for a radio station in the Amateur Radio Service.

(e) *Amateur radio station.* A station licensed in the Amateur Radio Service embracing necessary apparatus at a particular location used for amateur radiocommunication.

(f) *Primary station.* The principal amateur radio station at a specific land location shown on the station license.

(g) *Military recreation station.* An amateur radio station licensed to the person in charge of a station at a land location provided for the recreational use of amateur radio operators, under military auspices of the Armed Forces of the United States.

(h) *Club station.* A separate amateur radio station for use by the members of a bone fide amateur radio society and licensed to an amateur radio operator acting as the station trustee for the society.

(j) *Additional station.* Any amateur radio station licensed to an amateur radio operator normally for a specific land location other than the primary station, may be one or more of the following:

Secondary station. Station licensed for a land location other than the primary station location, i.e., for use at a subordinate location such as an office, vacation home, etc.

Control station. Station licensed to conduct remote control of another amateur radio station.

Auxiliary link station. Station, other than a repeater station, at a specific land location licensed only for the purpose of automatically relaying radio signals from that location to another specific land location.

Repeater station. Station licensed to automatically retransmit the radio signals of other amateur radio stations for the purpose of extending their intra-community radiocommuncation range.

(j) *Space radio station.* An amateur radio station located on an object which is beyond, is intended to go beyond, or has been beyond the major portion of the Earth's atmosphere. (Regulations governing this type of station have not yet been adopted and all applications will be considered on an individual basis.)

(k) *Terrestrial location.* Any point within the major portion of the Earth's atmosphere, including aeronautical, land and maritime locations.

(1) *Space location.* (reserved)

(m) *Amateur radio operation.* Amateur radiocommunication conducted by an amateur radio operator from an amateur radio station. May include one or more of the following:

Fixed operation. Radiocommunication conducted from the specific geographical land location shown on the station license.

Portable operation. Radiocommunication conducted from a specific geographical location other than that shown on the station license.

Mobile operation. Radiocommunication conducted while in motion or during halts at unspecified locations.

(n) *Remote control.* Control of transmitting apparatus of an amateur radio station from a position other than one at which the transmitter is located and immediately accessible, except that direct mechanical control, or direct electrical control by wired connections, of an amateur radio transmitter from a point located on board any aircraft, vessel, vehicle, or on the same premises on which the transmitter is located, shall not be considered remote control within the meaning of this definition.

(o) *Control link.* Apparatus for effecting remote control between a control point and a remotely controlled station.

(p) *Control operator.* An amateur radio operator designated by the licensee of an amateur radio station to also be responsible for the emissions from that station.

(q) *Control point.* The operating position of an amateur radio station where the control operator function is performed.

(r) *Antenna structures.* Antenna structures include the radiating system, its supporting structures and any appurtenances mounted thereon.

(s) *Antenna height, above average terrain.* The height of the center of radiation of an antenna above an averaged value of the elevation above sea level for the surrounding terrain.

(t) *Transmitter.* Apparatus for converting electrical energy received from a source into radio-frequency electromagnetic energy capable of being radiated.

(u) *Effective radiated power.* The product of the radio frequency power, expressed in watts, delivered to an antenna, and the relative gain of the antenna over that of a half-wave dipole antenna.

(v) *System Network diagram.* A diagram showing each station and its relationship to the other stations in a network of stations, and to the control point(s).

2. In Section 97.7, paragraph (c) is amended to read as set forth below and the note at the end of the Section is deleted.

§97.7 Privileges of operator licenses.

(c) *Technician Class.* All authorized amateur privileges on the frequencies 50.1–54.0 MHz and 145–148 MHz and in the amateur frequency bands above 220 MHz.

* * *

3. Section 97.37 is revised to read as follows:

§97.37 *General eligibility for station license.*

An amateur radio station license will be issued only to a licensed amateur radio operator, except that a military recreation station license may also be issued to an individual not licensed as an amateur radio operator (other than an alien or a representative of an alien or of a foreign government), who is in charge of a proposed military recreation station not operated by the United States Government but which is to be located in approved public quarters.

4. Section 97.40 is added to read as follows:

§97.40 *Station license required.*

(a) No transmitting station shall be operated in the Amateur Radio Service without being licensed by the Federal Communications Commission.

(b) Every amateur radio operator must have a primary amateur radio station license.

(c) An amateur radio operator may be issued one or more additional station licenses, each for a different land location, except that repeater station control station, and auxiliary link station licenses may also be issued to an amateur radio operator for land locations where another station license has been issued to the applicant.

(d) Any transmitter to be operated as part of a control link shall be licensed as a control station or as an auxiliary link station and may be combined with a primary, secondary, or club station license at the same location.

(e) A transmitter may only be operated as a repeater station under the authority of a repeater station license.

5. Section 97.41 is amended by modifying parapgraph (a), adding new paragraphs (b), (c), (d), (e) and (f), then redesignating former paragraphs (b) and (c) as (g) and (h).

§97.41 *Application for station license.*

(a) Each application for a club or military recreation station license in the amateur radio service shall be made on the FCC Form 610-B. Each application for any other amateur radio station license shall be made on the FCC Form 610.

(b) Each application shall state whether the proposed station is a primary or additional station. If the latter, the application shall also state whether the proposed station is a secondary, control, auxiliary link or repeater station.

(c) When an application(s) is made for a station having one or more associated stations, i.e., control station and/or auxiliary link station, a system network diagram shall also be submitted.

(d) Each application to license a remotely controlled amateur radio station, whether by wire or by radio control, shall be accompanied by a statement giving the address for each control point. The application shall include a functional block diagram and a technical explanation sufficient to describe the operation of the control link. Additionally, the following shall be provided:

(1) Description of the measures proposed for protection against access to the remote station by unauthorized persons.

(2) Description of the measures proposed for protection against unauthorized station operation, either through activation of the control link or otherwise.

(3) Description of the provisions for shutting down the station in case of control link malfunction.

(4) Description of the means to be provided for monitoring the transmitting frequencies.

(5) Photocopies of control station license(s) and auxiliary link station license(s), or the application(s) for same if such stations are proposed for the system network.

(e) Each application to license a control station or an auxiliary link station in the amateur radio service must be accompanied by the following information:

(1) The station transmitting band(s).

(2) Description of the means to be provided for monitoring the transmitting frequencies.

(3) The transmitter power input and justification that such power is in compliance with §97.67(b).

(4) If remote control of an auxiliary link station is proposed, all of the information required by paragraph (d) of this section shall also be provided.

(f) Each application to license a repeater station in the amateur radio service must include the following information for each frequency band proposed for operation.

(1) Location of the station transmitting antenna, drawn upon a topographic map having the scale of 1:250,000 and a contour interval of 50 feet. (Indexes and ordering information are available from U.S. Geological Survey, Washington, D.C. 20242, or Federal Center, Denver, Colorado 80225.)

(2) The transmitting antenna height above average terrain. (See appendix 5.)

(3) The effective radiated power in the horizontal plane for the main lobe of the antenna pattern, calculated for maximum transmitter output power.

(4) The transmitter power output with an explanation of the basis for the measurement or computation.

(5) The loss in the transmission line between the transmitter and the antenna expressed in decibels, and method of determination of the loss.

(6) The horizontal and vertical radiation patterns of the transmitting antennna as installed, with reference to True North (for horizontal pattern only), expressed as relative field strength (voltage) or in decibels, drawn upon polar coordinate graph paper, and method of determination of the patterns.

(7) The relative gain of the transmitting antenna in the horizontal plane and method of determination of the gain.

(8) If remote control of the repeater station is proposed, all of the information required by paragraph (d) of this section shall also be provided.

(9) If auxiliary link station(s) are also proposed, include photocopies of the auxiliary link station license(s), or the application(s) for such licenses.

* * *

6. Section 97.43 is revised to read as follows:

§97.43 *Location of Station.*

Every amateur station must have one land location, the address of which is designated on the station license. Every amateur radio station must have at least one control point. If the control point location is not the same as the station location, authority to operate the station by remote control is required.

7. In Section 97.47, the note following paragraph (c) is deleted and paragraphs (d) and (e) are added to read as follows:

§97.47 *Renewal and/or modification of amateur station license.*

* * *

(d) When an addition to the control point(s) authorized for a remotely controlled station is desired, an appli-

cation for modification of the remotely controlled station license shall be submitted. Authorized control points may be deleted by letter notification to the Commission.

(e) Should the licensee desire to effect changes to his station which would significantly change the system network diagram or other technical and operational information on file with the Commission, revised showings for the proposed alterations shall be submitted for approval. An application for modification of the station license is not required.

8. In Section 97.61, the introductory text of paragraph (a) is amended, and new paragraph (c) is added to read as follows:

§97.61 *Authorized frequencies and emissions.*

(a) Following are the frequency bands and associated emissions available to amateur radio stations, other than repeater stations, subject to the limitations stated in paragraph (b) of this section, §97.65, §97.109 and §97.110.

* * *

(c) The following transmitting frequency bands and the associated emission authorized in paragraph (a) of this section are available for repeater stations, including both input (receiving) and output (transmitting):

FREQUENCY BAND (MHz)
52.0 – 54.0
146.0 – 148.0
222.0 – 225.0
442.0 – 450.0

any amateur frequency above 1215 MHz. Frequency band 29.5–29.7 may be authorized upon a special showing of need for repeater station operation in this band for intra-community amateur radio communications.

9. Section 97.67 is revised to read as follows:

§97.67 *Maximum authorized power.*

The existing paragraph is revised by designating existing text as paragraph (a) and by adding new paragraphs (b) and (c) to read as follows:

* * *

(b) Notwithstanding the provisions of paragraph (a) of this section, amateur stations shall use the minimum amount of transmitter power necessary to carry out the desired communcations.

(c) Within the limitations of paragraphs (a) and (b) of this section, the effective radiated power of a repeater station shall not exceed that specified for the antenna height above average terrain in the following table:

Antenna height above average terrain	Maximum effective radiated power for frequency bands above:			
	52 MHz	146 MHz	442 MHz	1,215 MHz
below 50 feet	100 watts	800 watts	Paragraphs (a) and (b)	
50 to 99 feet	100 watts	400 watts	Paragraphs (a) and (b)	
100 to 499 feet	50 watts	400 watts	800 watts	Paragraphs (a) and (b)
500 to 999 feet	25 watts	200 watts	800 watts	Paragraphs (a) and (b)
above 1,000 feet	25 watts	100 watts	400 watts	Paragraphs (a) and (b)

10. In §97.79, the headnote and text are revised to read as follows:

§97.79 *Control operator requirements.*

(a) The licensee of an amateur station shall be responsible for its proper operation.

(b) Every station when in operation shall have a control operator at an authorized control point. The control operator may be the station licensee or another amateur radio operator designated by the licensee. Each control operator shall also be responsible for the proper operation of the station.

(c) An amateur station may only be operated in the manner and to the extent permitted by the operator privileges authorized for the class of license held by the control operator, but may exceed those of the station licensee provided proper station identification procedures are performed.

(d) The licensee of an amateur station may permit any person to participate in amateur radiocommunication from his station, provided that a control operator is present and continuously monitors the radiocommunication to ensure compliance with the rules.

11. In Section 97.87, paragraph (d) is amended and redesignated as (h) and new paragraphs (d), (e), (f), and (g) are added as follows:

§97.87 *Station Identification.*

* * *

(d) Under conditions when the control operator is other than the station licensee, the station identification shall be the assigned call sign for that station. However, when a station is operated within the privileges of the operator's class of license but which exceeds those of the station licensee, station identification shall be made by following the station call sign with the operator's primary station call sign (i.e. WN4XYZ/W4XX).

(e) A repeater station shall be identified by radiotelephony or by radiotelegraphy when in service at intervals not to exceed five minutes at a level of modulation sufficient to be intelligible through the repeated transmission.

(f) A control station must be identified by its assigned station call sign unless its omissions contain the call sign of its associated station.

(h) The identification required by paragraph (a), (b), (c), (d), (e), (f) and (g) of this section shall be given on each frequency being utilized for transmission and shall be transmitted either by telegraphy using the International Morse Code, or by telephony, using the English language. If by an automatic device only used for identification by telegraphy, the code speed shall not exceed 20 words per minute. The use of a national or internationally recognized standard phonetic alphabet as an aid for correct telephone identification is encouraged.

12. Section 97.89 is amended to read as follows:

§97.89 *Points of Communications.*

(a) Amateur stations may communicate with:

(1) other amateur stations, except those prohibited by Appendix 2.

(2) stations in other services licensed by the Commission and with United States Government stations for civil defense purposes in accordance with Subpart F of this Part, in emergencies and, on a temporary basis, for test purposes.

(3) any station which is authorized by the Commission to communicate with amateur stations.

(b) Amateur stations may be used for transmitting signals, or communications, or energy, to receiving apparatus for the measurement of emissions, temporary observation of transmission phenomena, radio control of remote objects, and similar experimental purposes and for the purposes set forth in §97.91.

(c) Notwithstanding the provisions of paragraph (a), no more than two repeater stations may operate in tandem, i.e., one repeating the transmissions of the other, excepting emergency operations provided for in §97.107 or brief periods to conduct emergency preparedness tests.

(d) Control stations and auxiliary link stations may not be used to communicate with any other station than those shown in the system network diagram.

13. Section 97.95 paragraph (a) (1) is amended as follows:

§97.95 *Operation away from the authorized permanent station location.*

(a)

(1) When there is no change in the authorized land station location, the amateur radio station other than a military recreation or an auxiliary link

station may be operated under its station license anywhere in the United States, its territories or possessions as a portable or mobile operation, subject to §97.61.

* * *

14. Section 97.97 is revised to read as follows:

§97.97 *Notice of operation away from authorized location.*

Whenever an amateur station is, or is likely to be, in portable operation at a single location for a period exceeding 15 days, the licensee shall give advance written notice of such operation to the Commission's office specified in §97.95. A new notice is required whenever there is any change in the particulars of a previous notice or whenever operation away from an authorized station continues for a period in excess of one year. The notice required by this section shall contain the following information:

(a) Name of licensee

(b) Station call sign

(c) Authorized station location shown on station license

(d) Specific geographical location of station when in portable operation

(e) Dates of the begnning and end of the portable operation

(f) Address at which, or through which, the licensee can be readily reached.

15. Section 97.103 is revised to read as follows:

§97.103 *Station log requirements.*

An accurate legible account of station operation shall be entered in a log for each amateur radio station. The log shall bear the call sign of the station and the signature of the licensee. The following information shall be recorded as a minimum:

(a) Written entries for all stations which are required only once, or when there is a change thereto.

(1) The signature of the control operator on duty and the call sign of his primary station, if he is other than the station licensee.

(2) The location of the station. Stations in mobile operation may enter the word "local" for amateur radiocommunication conducted within 100 statute miles of the address shown on the station license, otherwise the location of the first and last radiocommunication of each day. Stations in mobile or portable operation shall make an entry showing compliance with §97.97, if required.

(3) The input power to the transmitter final amplifying stage.

(4) The type of emission used.

(5) The frequency or frequency sub-band used for transmitting.

(b) Other entries for all stations which may be recorded in a form other than written but which can readily be transcribed by the licensee into written form:

(1) The dates of operation.

(2) Except for repeater stations, names of persons other than the control operator using the station, either directly or indirectly, for amateur radiocommunication.

(3) A notation of third party messages sent or received, including names of all participants and a brief description of the message content.

(4) The call sign of each station actually contacted, or other purpose of the transmission, i.e., those set forth in §97.89. Stations in mobile operation and repeater stations may omit this entry. Control stations shall enter the call sign(s) of each station in the control link. An auxiliary link station shall enter the call sign of its associated station(s).

(5) All stations shall enter the times when the station is put into, or taken out of, service. Stations other than those in mobile operation, control stations, auxiliary link stations, and repeater stations shall enter the times of commencing and terminating each exchange of radiocommunication.

16. Section 97.105 is revised as follows:

§97.105 *Retention of logs.*

The station log shall be preserved for a period of at least 1 year following the last date of entry and retained in the possession of the licensee. Copies of the log, including the sections required to be transcribed by §97.103, shall be available to the Commission for inspection.

17. Section 97.111 is redesignated as 97.112 and a new undesignated center heading and Sections 97.108 through 97.111 are added to read as follows:

Operation of additional stations.

§97.108 *Operation of a remotely controlled station.*

(a) An amateur radio station may be operated by remote control only from an authorized control point, and only where there is compliance with the following:

(1) The license for the remotely controlled station must list the authorized remote control point(s). A photocopy of the remotely controlled station license must be posted in a conspicuous place at the authorized control point(s), and at the remotely controlled transmitter location. A copy of the system network diagram on file with the Commission must be retained at each control point. The transmitting antenna, transmission line, or mast, as appropriate, associated with the remotely controlled transmitter must bear a durable tag marked with the station call sign, the name of the station licensee and other information so that the control operator can readily be contacted by Commission personnel.

(2) The control link equipment and the remotely controlled station must be accessible only to persons authorized by the licensee. Protection against both inadvertent and unauthorized deliberate emissions must be provided. In the event unauthorized emissions occur, the station operation must be suspended until such time as adequate protection is incorporated, or there is reasonable assurance that unauthorized emissions will not recur.

(3) A control operator designated by the licensee must be on duty at an authorized control point while the station is being remotely controlled. Immediately prior to, and during the periods the remotely controlled station is in operation, the frequencies used for emission by the remotely controlled transmitter must be continuously monitored by the control operator. The control operator must terminate transmission upon any deviation from the rules.

(4) Provisions must be incorporated to automatically limit transmission to a period of no more than three minutes in the event of malfunction in the control link.

(5) A remotely controlled station may not be operated at any location other than that specified on the license without prior approval of the Commission except in emergencies involving the immediate safety of life or protection of property.

(6) A repeater station may be operated by radio remote control only where the control link utilizes frequencies other than the repeater station receiving frequencies.

§97.109 *Operation of a control station.*

(a) Amateur frequency bands above 220 MHz, excepting 435 to 438 MHz, may be used for emissions by a control station. Frequencies below 225 MHz used for control links must be monitored by the control operator immediately prior to, and during, periods of operation.

(b) Where a remotely controlled station has been authorized to be operated from one or more remote control stations, those remote control stations may be operated either mobile or portable.

§97.110 *Operation of an auxiliary link station.*

(a) An auxiliary link station may use amateur frequency bands above 220 MHz excepting 435 to 438 MHz for emissions. Frequencies below 225 MHz used by an auxiliary link station shall be monitored by the control operator immediately prior to, and during, periods of operation.

(b) An auxiliary link station may only be used for fixed operation from the location specified on the station license, and only when its associated station(s) is operated from its authorized land location.

§97.111 *Operation of a repeater station.*

(a) Emissions from a repeater station shall be discontinued within five seconds after cessation of radiocommunication by the user station. Provisions to automatically limit the access to a repeater station may be incorporated, but are not mandatory.

(b) The transmitting and receiving frequencies utilized by the repeater station shall be continously monitored by the control operator immediately prior to, and during, periods of operation.

(c) A repeater station may be concurrently operated on more than one frequency band, provided the necessary showings have been approved by the Commission for each frequency band of operation. Crossband operation of repeater stations is prohibited, i.e. both input (receiving) and output (transmitting) frequencies for a particular repeated transmission must be within the same frequency band. Operation on more than one output frequency on a single frequency band is prohibited except when specifically approved by the Commission. Repeater stations authorized to operate in conjunction with one or more auxiliary link stations may utilize an input frequency in a different frequency band provided the input frequency of the auxiliary link station(s) is in the same frequency band as the output frequency of the repeater station.

(d) A repeater station shall be operated in a manner so as to assure that the station is not used for one-way radiocommunication other than provided for in §97.91.

(e) A station licensed as a repeater station may only be operated as a repeater station, excepting for short periods for testing or for emergencies.

18. In Section 97.193, the introductory text of paragraph (a) is amended, and a new paragraph (e) is added to read as follows:

§97.193 *Frequencies available.*

(a) Except as provided in paragraph (e) of this section, the following frequency and frequency bands and associated emissions are available on a non-exclusive basis to the individual class of stations or units of such stations in the Radio Amateur Civil Emergency Service.

(e) A repeater station in the Radio Amateur Civil Emergency Service may operate on any frequency, and with any associated emission, above 50 MHz listed in paragraph (a) of this section, except for 220 MHz to 333 MHz.

19. Appendix 2 is amended by adding a footnote to Section 1:

Sec. 1. Radio communications between amateur stations of different countries[1] shall be forbidden if the administration of one of the countries concerned has notified that it objects to such radiocommunications.

20. Appendix 5 is added, reading as follows:

APPENDIX 5
DETERMINATION OF
ANTENNA HEIGHT
ABOVE AVERAGE TERRAIN

The effective height of the transmitting antenna shall be the height of the antenna's center of radiation above "average terrain." For this purpose "effective height" shall be established as follows:

(a) On a United States Geological Survey Map having a scale of 1:250,000, lay out eight evenly spaced radials, extending from the transmitter site to a distance of ten miles and beginning at 0°, T (0°, 45°, 90°, 135°, 180°, 225°, 270°, 315° T). If preferred, maps of greater scale may be used.

(b) By reference to the map contour lines, establish the ground elevation above mean sea level (AMSL) at 2, 4, 6, 8, and 10 miles from the antenna structure along each radial. If no elevation figure or contour line exists for any particular point, the nearest contour line elevation shall be employed.

(c) Calculate the arithmatic average of these 40 points of elevation (5 points of each of 8 radials).

(d) The height above average terrain of the antenna is thus the height AMSL of the antenna's center of radiation, minus the height of average terrain as calculated above.

Note 1: Where the transmitter is located near a large body of water, certain points of established elevation may fall over water. Where it is expected that service would be provided land areas beyond the body of water, the points at water level in that direction should be included in the calculation of average elevation. Where it is expected that service would not be provided to land areas beyond the body of water, the points at water level should not be included in the average.

Note 2: In instances in which this procedure might provide unreasonable figures due to the unusual nature of the local terrain, applicant may provide additional data at his own discretion, and such data may be considered if deemed significant.

[1] as may appear in public notices issued by the Commission.

NEW FCC REGULATIONS

Effective November 22nd there will be some changes in the 10, 15, 40 and 80m bands. These changes are the result of the efforts to set up more voice bands in recognition of the high percentage of amateurs using voice instead of CW.

On the 80m band the Extra Class phone segment was extended 25 kHz down to 3775 kHz. On 40m the phone band was extended down to 7150, thus moving the Novice band down to 7100-7150 kHz. American stations outside of Region 2 may also use phone in the 7075-7100 kHz band. The 15m Novice band was cut back, with 21.2-21.25 being deleted from Novice use. A new Novice band was opened on 10m, running from 28.1 to 28.2 MHz. Because of the extensive changes in the Novice bands the requirement for crystal control was removed. How about that!

NEW FCC REPEATER PETITIONS

PETITION: To extend amateur repeater operation to the 440–442 MHz band.

The recent Commission report and order (8-29-72) restricts repeater operation in the amateur 420 MHz band to the frequencies 442–450 MHz.

Since this is completely contrary to the self regulating frequency allocations set up by the amateurs, a system which has been working quite satisfactorily, and which has been responsible for the orderly growth of the 420 MHz band in all parts of the country, implementation of the new Commission regulation would disrupt the work of the last decade – it would cause considerable hardship and expense – it would be a slap in the face of those serious amateurs who have labored so hard over the years to keep the growth and development of this band orderly.

THE 420 MHz PLAN

Amateurs have been working together with remarkably good results to bring about an orderly use of the 420 MHz band. When you consider the variety of groups and individuals involved, the self restraint has been admirable.

Repeaters and repeater control links have been self-allocated to the 440–450 MHz segment of the band, with the exception of southern California where this segment has been filled and some allocations have been made in the 420–430 MHz segment. The allocation by the Commission of repeaters to the 442–450 MHz segment of the band could have the impact of forcing repeater link stations to move out of this segment and into the 420–430 MHz part of the band – a part which has presently been allocated by amateurs to fast scan television experimentation.

There has been no demonstrated need for a change in the amateur self allocation scheme. It has been working well and with effectiveness. The heavy hand of the Commission was not needed in any way and is quite undesirable.

If the Commission would limit itself to regulations for which there is some demonstrated need, the amateur service would be able to progress and grow with the times.

Amateur radio is important to the United States and to the world. The future of business and government is largely electronic and any moves made by the Commission which tend to limit the number of youngsters who take up this hobby which is the entryway to a professional career cannot be considered as other than detrimental to the good of the country.

The Commission is all too familiar with the future of electronics and communications as a major part of the activities of the Commission are involved with trying to cope with the changes that these developments bring about. There is going to be a need – a great need – for more and more engineers and technicians to design, build, install, operate and service the electronic future that all of us see ahead. What a disaster if the Commission should make moves today which would make amateur radio less attractive as a hobby and thus precipitate a shortage of trained professionals a few years hence.

The results of the Commissions' adventure with "incentive licensing" should serve as a warning. To some degree that change in the amateur regulations – and the threat of it – turned away tens of thousands of youngsters who might otherwise have become radio amateurs. How much of the sudden drop in growth of amateur radio was attributable to incentive licensing and how much to the FCC license fees is debatable, but the effect is not.

During the ten year period from 1951 to 1961 the number of operators grew from 88,729 to 216,720 (FCC figures), a growth of about 9% per year average. During the period 1961 to 1971 the growth was only about 68,000, an average of about 2½% per year. During the years of Commission indecision on incentive licensing the growth was miniscule, going from 256,237 in 1964 when the Commission put the matter on the docket to 260,294 in 1968 when it was finally concluded. During four years the amateur service grew by only 4,000 operators.

Had it not been for the interference by the Commission it seems likely that the growth pattern of the service would have continued as it had for many previous years and we would today have about 600,000 operators. When one considers what that would mean in terms of service in times of emergency – in manpower lost to industry and the military – it is a terrible loss.

The Commission is begged to stop this trend toward unnecessary restriction of the amateur service. When there is no clearly demonstrated need for regulation of amateurs we beseech the Commission to leave us alone – and there is no clear or even indistinct call for regulations prohibiting the use of amateur repeaters in the 440–442 MHz segment of the band.

PETITION:

It is hereby petitioned that the FCC permit repeater operation in the 440–442 MHz amateur band. It is requested that section 97.111(c) be changed to indicate that repeaters may use the 440–450 MHz segment of the band; and that in section 97.67 the table of authorized power be changed to read 440 MHz instead of 442 MHz.

Wayne Green
Peterborough NH 03458
18 September 1972

PETITION: To permit crossband linking of repeaters.

The recent Commission report and order (80334) prohibits crossband operation of repeaters (97.111(c).

This ruling would seem to be in basic opposition to the very fundamental spirit and purposes of the amateur service. It is unnecessarily restrictive in that it prevents the application of amateur ingenuity which would otherwise be devoted to the development of multiband communications systems – systems which could hardly fail to be of extreme value in times of emergency – systems which would tax amateur ingenuity and further demonstrate his ability to design and build equipment to meet demands far beyond those of commercial applications.

CLASSES OF LICENSE

With the restriction of repeaters in all of the amateur bands to frequencies allocated to all classes of license, from Technician through Extra Class, there cannot be any question of the repeating of a Technician operating on his own authorized frequencies into a band for which he is not licensed. Thus there can be no such excuse given for limiting or prohibiting cross band operation of repeaters.

FREQUENCY CONSERVATION

The availability of several different 220 MHz transceivers would seem to put any questions of overoccupancy of repeaters in any one area far enough in the future so there could be little reason for ruling against current

uses of repeaters on the grounds of possible distant future crowding.

The fact is that even in the most congested areas we have adequate spectrum space for double or triple the number of repeaters that are presently active in the amateur service. Further, few of the repeaters are kept active for more than a few hours a day.

It is interesting to note that such time consuming services as autopatch tend to be used less and less as other uses develop for a repeater. The busiest repeater in the country, WA2SUR, has autopatch facility, but the over 400 active users of the repeater keep it so busy that operators wanting to use the autopatch switch channels to less active repeaters.

The same tendency would tend to limit the use of any repeater for cross band operation, in all probability. Cross band operation would generally tend to be used during times when regular repeater activity is at a minimum.

This has certainly proven to be the case with the WA1KGO repeater. This repeater is active on 146.19–146.79 MHz and can be interconnected with 52.525 MHz by use of tone access. In practice the 146 MHz activity takes precedence and cross band operation is only attempted when the repeater is not otherwise in use.

It would seem unreasonable to prohibit cross band connection of repeaters on the basis of frequency conservation.

CROSSBANDING BASE STATIONS

Since there is no prohibition of interconnecting a 146 MHz signal on any other band when an intermediary operator is present, it does not seem reasonable or logical to differentiate against repeaters. If there are adequate safeguards built into the system, an automatic cross connection between two bands should be the same as if it were being done by a third operator.

There is nothing illegal if I am in contact with an amateur station on 146 MHz and one on 52.525 MHz simultaneously in a three-way contact with me rebroadcasting each of the other two operators so they can hear the entire contact. For that matter there is nothing illegal in my transmitting any class of license on any band permitted me by my license as long as I am in control.

The new regulations spell out in detail that someone must be in control of a repeater station at all times – so where is the difference between the repeater and a base station? In each case there is an operator in constant control, yet with the base station cross banding is permitted and with the repeater it is not. This does not seem logical, reasonable or fair.

INCENTIVE LICENSING?

The concept that amateurs might use repeaters to circumvent the band allocations set up in recent years for different classes of license has no basis in fact. It is technically possible, of course, for an amateur with a Technician license, to operate through a repeater and work 20 meters, complete with a kilowatt, rotary beam, and first class location and receiver. But since this has never happened, to my knowledge, and seems unlikely to happen, the need for regulations prohibiting it seem uncalled for – and the side effects of the regulations so damaging and prohibitive to amateur ingenuity and progress as to be worthy of immediate reconsideration.

The amount of ingenuity required for automatic remote operation of a low band station seems sufficient to be self regulating.

There is something to be said about the possibility of the limited use of cross band to a lower band as an incentive toward getting a higher class of license. The Technician who has never made an international contact might be impressed enough if he were able to occasionally do this via a repeater to get a higher grade of license so he could set up his own low band station. In my experience, many Technicians have no idea what they are missing.

But, since the repeater regulations restrict all repeater operation to bands usable to all classes of license above Novice, the matter of repetition outside of the license restrictions is not pertinent.

INTERCONNECTING SYSTEMS

Amateurs have repeater systems operating in all of the VHF bands, 52 – 146 – 220 – 450 MHz. Each band is relatively isolated at present, with one group on 52 MHz, another on 146 MHz, etc. Indeed, unless one is to jam a car full of expensive equipment, there is no practical way of operating all of these bands with a mobile station. Four transceivers and the array of antennas on the car would provide a very tempting target for thieves.

A four band mobile installation could easily cost more than the car. Even using the latest solid state equipment, it would take a large car to leave room for the driver once the four stations were installed.

If a few repeaters were permitted to interconnect the different systems, it would be possible for a mobile operator to talk with any of the four groups in his vicinity. Hopefully it is not necessary to point out the tremendous value of this flexibility in time of emergency. Without such an interconnection the four systems would be individual and in many instances three of them would be wasted.

With suitable safeguards it should be possible to permit repeaters to be interconnected. Since all repeaters are under constant supervision and control, they can be shut down at any time that trouble develops, though amateur ingenuity should not be seriously taxed in providing automatic disconnection of such functions when problems arise.

PETITION:

The Commission is requested to permit crossbanding of repeaters, provided adequate safeguards are built into the system to disable it in case of difficulty.

A deletion of the second sentence of section 97.111(c) is requested.

September 1972

PETITION: Expansion of repeater frequencies in the 220–225 MHz amateur band.

REPEATER MAIN USERS

Though amateurs have had the 220–225 MHz band for many years, the activity in that band has been slight. This has been the result of many circumstances such as the lack of suitable military surplus equipment which could be modified for operation on this band, the lack of commercial surplus equipment for the band, the lack of commercial amateur equipment for the band, the power limitations which prevailed for that band for many of the earlier years thus discouraging moonbounce and weak signal work, the narrowness of the band which precluded television experimentation, the availability of commercial and military surplus equipment for the adjacent amateur bands (thus encouraging their use over the 220 MHz band), the pre-emption of the band for military use on a priority basis, and other considerations.

The rapid growth of repeater FM operations in the 146 MHz band indicate that, even with the expansion of that band to the 147 MHz segment, an end is in sight in many areas of the country for repeater channels. The obvious band for further repeater development is the 220 MHz band. Indeed, amateurs and repeater groups have recognized this and a series of FM symposiums have been held to coordinate the development of repeaters in this band. Over two hundred repeater groups have agreed to set up repeaters on the 220 MHz band as soon as practical. Many have already fulfilled this agreement and there are an estimated 70 repeaters actually in operation around the country at this date.

Since the users, other than FM repeaters, have not successfully developed the 220 band in the years that it has been available, it does not seem likely that any great influx of them can be expected in the future. The fact is that 220 MHz offers little for the AM or CW operator over operation on 144 MHz. There is no shortage of open channels on the 144 MHz band for these operators, and there are far more stations to contact. The few stations active on the 220 band (other than repeaters) are not likely to attract much more company.

There is no amateur radio development in sight on any horizon which would provide activity in any substantial numbers in the two MHz left open by the new regulations.

In the forseeable future it would appear that the bulk of the activity that can be expected to develop on the 220 MHz band would be repeaters. The need is there — the equipment is being manufactured — the interest of the amateurs is there. Everything would appear to be favorable for extensive repeater use of this band.

In the face of this need and prospective growth, the deletion of 40% of the band from repeater use would seem to the detriment of the amateur service.

NEW EQUIPMENT

Several manufacturers have taken note of the growth possibilities of the amateur 220 MHz band and have been working diligently to provide good FM transceivers for this band. TPL has a 220 transceiver in production which will sell for around $250. Henry Radio has a fine 220 FM transceiver which should sell at around $300. The Clegg 21 is in production. And several other companies are rushing transceivers into production for this band.

Both TPL and Clegg are also working on repeaters for the band and they should be available before the end of the year.

The lack of equipment which has previously limited the use of this band by amateurs would seem to be ending shortly.

SELF REGULATION

Amateurs have clearly shown the Commission that they have little need for restrictive rules and regulations and are quite capable of keeping their own house in order. This has been particularly true as far as the 220 MHz band is concerned.

The FM symposiums held earlier this year in the east, midwest and west developed national agreements on 220 MHz repeater input and output channels, repeater channel allocations, frequency coordination to keep interference to a minimum, deviation standards, simplex channels, control frequencies, etc. Repeater councils have been established in most parts of the country to deal with any problems that do come up.

WHY NOT OPEN 220–222 MHz?

Since the use of this band by other than FM repeaters is negligible and would seem to be negligible for the forseeable future, there would seem to be no adequate reason for the Commission to prohibit the use of the entire band by repeaters.

Perhaps it should be pointed out that the amateurs have agreed to leave the 222–223 MHz segment of the band open for non-repeater use, and have also agreed to leave the lower part of the 220 MHz segment open for continued use by the few present AM and CW users.

What purpose can there be for the Commission to make a rule which will essentially leave two MHz of this band open and almost totally unused? The only possibility that suggests itself is one which is certainly unbecoming of the Commission, though it seems almost inescapable: this regulation would seem to pave the way for a deletion of all or part of this two MHz from the amateur service and thus make it available for citizens band service as is being fervently urged by the Electronics Industries Association.

In the absence of any Washington lobby on the part of the amateurs, there would seem little that amateurs can do to preserve their bands against the pressures of money and influence of big business. The amateurs have depended entirely upon the Commission to be honest and protect their future, having no organization of their own to lobby for them and thus provide this protection.

The net gain to amateurs using the 220 MHz band, should the Commission return the lower two MHz for repeater use, would be one MHz, since the middle MHz has been allocated to non-repeater uses. This segment, from 222–223 MHz is in active use by non-repeater groups right now and has several advantages which make it desirable for this use: the freedom from radar interference which is more serious in the lower parts of the band — and the freedom from adjacent channel interference from television transmitters (and interference to television sets) which results from operation on the lower part of the band. The upper part of the band suffers seriously from spurious emissions of television sets and is less desirable as a result. The result of these and other factors is that the most valuable part of the band for weak signal operations is in the middle part of the band in most areas of the country.

Repeater use of the high end of the band for inputs would seem to be ideal since most repeater receivers are normally situated far enough away from television sets so they would tend to receive little interference from spurious emissions.

The low end of the band would seem better for repeater outputs since their remoteness from television sets would cause much less adjacent channel interference or front end overload to television sets.

The plan that emerged from the FM symposiums would seem to best consider all of the presently known factors as far as amateur utilization of the band is concerned — with the exception of leaving two MHz open and unused for allocation to a new citizens band.

The difference in the number of repeater channels which will be available to amateurs is important. If repeaters are kept to but 3 MHz of the band this would permit perhaps 34 repeater channels using 40 kHz splits instead of the 50 that would result from using 4 MHz.

There are an estimated 30,000 radio amateurs presently active using FM repeaters on 146 MHz. The total population of licensed amateurs is presently about 285,000, according to the latest FCC and Callbook figures. If we make allowances for second stations, licensed wives and children, this still gives us about 210,000 amateurs who might be users of repeaters.

At present amateurs are using approximately fifty 146 MHz repeaters in the New England area. If we project this forward we find that we could need as many as 350 repeaters in the area to handle the activity. The two meter band will probably be able to hold one hundred of these. Obviously the 220 MHz band will be strained to provide the repeater channels that could be needed.

PETITION:

The FCC is hereby petitioned to reopen the entire 220–225 MHz amateur band for repeater use.

It is hereby requested that section 97.61(c) be ammended to read 220–225 MHz instead of the present 222.0–225.0 allocation.

Wayne Green W2NSD/1

September 1972

PETITION: To drop the requirement that a repeater be constantly monitored by a control station during operation.

Amateur automatic relaying stations — repeaters — serve several uses. It is important to consider these uses when devising restrictions and setting them up to limit possible misuses, while not interfering with the uses.

Repeater stations extend the range of communications of amateur base, mobile and hand transceivers, making it possible for amateurs in a fairly wide area to establish contact. As an example, the repeater station atop Mt. Mansfield in Vermont makes it possible for amateurs in northern New Hampshire, northern Vermont, northeastern New York and adjacent sections of Quebec and Ontario to maintain contact with ten watt mobile units. For instance, I have no trouble using this repeater from New Hampshire, fifty miles away, with a one watt handy-talky to talk with mobile amateurs in Ontario over 200 miles away.

The amateur service provides a supply of trained operators and equipment for use in times of emergency, as well as technical developments which benefit industry and the country. But amateur radio is able to provide the service that it does because of the hobby it provides. The equipment amateurs buy or build or convert is bought with personal funds – funds on which the government has already extracted an income tax. Amateurs will continue to invest this time and money as long as the Commission does not prevent the enjoyment of the hobby which spurs this investment.

The latest report and order by the Commission is not calculated to increase the enjoyment of the hobby – and to that extent will be detrimental to the service that amateurs provide.

The Commission must be aware that in every serious emergency communications falls upon local amateurs. The recent devastation in Pennsylvania was typical of the emergency situations which amateurs encounter and can serve as an example and model.

After trying for several days to handle emergency communications via the lower amateur bands, the importance of a repeater was so apparent that one was flown from a factory over a thousand miles away and set up in the disaster area. The Civil Defense communications, largely set up in basements, were flooded out. Police were too busy with their own problems to provide health and welfare message service or to help the stricken Civil Defense groups. Citizens band operators tried to help, but interference on their channels from skip stations running high power, their lack of range due to low power, and their lack of training in handling messages rendered them only of limited use. Only amateur radio was able to step in and provide the short, medium and long range communications needed.

Once the repeater had been set up, the emergency coordinators in the area had to put out a call for portable and mobile FM stations and operators to come from outside to help since the local amateurs were not set up for FM and repeaters. A helicopter was sent to the Clegg factory to pick up a dozen of the newest FM transceivers and these were put to immediate good use by local amateurs. FM amateurs from hundreds of miles around responded.

If FM and repeaters had already been established in the flood area it would have been possible for amateurs to provide much better service early in the emergency. It would seem important for the Commission to keep in mind the end effect of each new regulation and weigh it in terms of how it might affect the communications capability that amateurs can provide. The requirement that a control operator continuously monitor a repeater while it is in service is so extremely restrictive as to be severely damaging to the amateur service.

The Commission requirement that a repeater station be controlled via a control and link station on a band above 225 MHz sets definite limitations as to the practical number of control points that can be used, both from a license fee and cost of equipment standpoint. The addition of 450 MHz control equipment to the 146 MHz transceiver in a car would more than double the investment necessary for the mobile installation – and would require a second communications type antenna on the car, thus making it stand out substantially from others and be an inviting target for thieves.

The practical result of the Commission requirement for monitoring at a control point during repeater service is that few repeaters would be in service through the night or during regular working hours of the day. There would be exceptions, of course, where a control operator happened to be an engineer at an all night radio or television station, or the like. These would more likely be the exception rather than the rule.

Repeaters which are turned off a good deal of the time are not very valuable in times of emergency. In some areas it is possible to have a choice of repeaters and it might be feasible to try one channel after another to find a repeater in service. In most areas a mobile operator has little choice and if the repeater within his range is off he is helpless.

It is much more likely that someone somewhere might be listening to the repeater, even though all of the four or five control operators might be asleep, and provide help. And, in the case of the repeater with autopatch, no operator at all is needed to provide help since police or others can be notified directly through the repeater and the telephone line. The proliferation of scanning receivers makes it even more likely that someone who is awake would be on hand to render service in time of emergency.

Emergencies come in all sizes, from earthquakes and wars to a warning to the wife that you are going to be late. The Commissioner who does not consider notification of late arrival to a wife an emergency must be a bachelor.

There are lesser emergencies where repeaters are helpful. Many amateurs use repeaters when they are driving late at night and through the early morning hours to help keep them awake. Two drivers a hundred miles apart can keep each other awake and alive. To be personal about it, I now undertake long drives at night that I would never undertake without the safety of open repeaters along the way. I know that I will not fall asleep and that should anything happen to my car that I will be able to reach help immediately. If all these repeaters were to be turned off, as the Commission regulations will almost certainly force, many amateurs would suffer along with me.

In this day of integrated circuits there is little problem for amateurs to build and maintain the sophisticated circuits which will enable a repeater station to operate without immediate direct control. With timers set to disable the repeater when trouble develops anywhere in the system, little can go wrong. The fact is that there are about one thousand amateur repeater stations in operation in the U.S. today and the number of problems they cause are very few. The Commission requirement to continuously monitor the input and output of the repeater does not seem to serve the purpose of correcting any existing problem.

As the editor and publisher of the one amateur magazine which has specialized in FM and repeaters and the publisher of a monthly bulletin providing communications to all of the repeater users and operators in the northeastern U.S., and as the publisher of virtually all of the many books on the subject of FM and repeaters, I am perhaps in better communications with the repeater situation as it is in 1972 than most other people.

I would ask that the Commission keep in mind that the comments received on Docket 18803 were sent in over two years ago and reflect, if anything, the state of the art at that time and the thinking of those with experience in the field at that time.

Since then FM and repeaters have grown enormously and the state of the art has changed markedly. There are about 400% more amateurs using FM and repeaters today – there are perhaps 300% more active repeaters, minimum.

In my experience the problems that amateurs are having with repeaters are few and, in virtually every case, are easily solved by the amateurs themselves. There has been no demonstrated need for extensive and extremely restrictive regulations. Repeaters are quite capable of being set up by amateurs to run automatically without perpetual monitoring and it is in the interest of the hobby and the service it provides that repeaters be so set up in most cases.

Amateur repeater technicians and groups will provide any sort of reasonable safeguard that the Commission requires to assure that an automatic unmonitored repeater station is not operated in a way that will cause problems for other services or for other amateurs. The repeater councils have clearly demonstrated that amateurs are quite capable of self government and handling all but the most serious problems that arise. Amateurs have been able to arbitrate and agree on repeater channels, on interference between repeaters on the same channels, and all other problems attendant to the growth of this valuable service. The fact that problems have arisen is of much less importance than the demonstrated ability of the amateurs to surmount them unaided by the Commission. About the only serious difficulties where amateurs have need of help from the Commission has been in cases of illegal jamming of a few repeaters and the occasional use of abusive language. These cases have been so few and far between that they are not and have never been a substantial problem. And this is a problem that amateurs face on all bands, not just via repeaters.

The Commission gives no reason for the ruling on continuous monitoring, so it is difficult to provide arguments. Indeed, it is difficult to even imagine why such a ruling could ever have been made. It seems to serve no useful purpose and seems so unnecessarily prohibitive and restrictive to the whole fabric of amateur radio as to be worthy of immediate change.

PETITION:

To delete the ruling which requires a repeater control operator to monitor the input and output of the repeater continuously. It is requested that the words "and during," in section 97.111b be struck from the regulations, and that 97.109a and 97.110a be changed to eliminate "and during" in the cases of remote control or link operation of a repeater.

Drop her a hint that this is the Christmas Present you really want this year . . .

The **INOUE IC-21** at **$399.95** is the premium 2 meter transceiver on the market today. Surely you deserve only the best as your very own Christmas present. I know she will approve, as nothing makes the Christmas Day more enjoyable than having a happy 2 meter ham.

JUST TELL HER TO SEND A CHECK TODAY TO:

ADIRONDACK RADIO SUPPLY, INC.
INOUE DEPT.
185 West Main St. Box 88
Amsterdam, New York 12010

We'll do our part to make a Merry Christmas for you by immediately shipping out your rig. Also, we're going to enclose a little Christmas present for her for being so nice to both of us.

LOW NOISE ECONOMY PREAMP FOR 2M

Low gain is almost a meaningless parameter in an rf preamplifier specification unless some notation is made about the noise characteristics of the circuit. A gain of 20–30 dB is not uncommon in a VHF preamplifier with a single semiconductor of modern vintage. But if the active device tends to generate and amplify noise, that healthy signal could be reduced to such an extent that copy is actually better with the preamp completely out of the receiver circuit. A signal-to-noise-ratio measurement made before installing the preamp should, under ideal conditions, read the same with the preamp *in* the circuit provided the *specified* gain is actually the effective gain – which, unfortunately, is rarely the case. In practice, the effective gain of a typical two meter preamp is considerably less than half the rated gain!

Bandwidth is another parameter worthy of a builder's consideration. A broad amplification curve might be a real blessing for the frequency-hopper who operates at the low end of the band one night and at the other end the next, providing he's not trying to operate from an area noted for spectrum congestion. The fact is, the broader the bandwidth of the preamp, the more likely the receiver will be to be "swamped out" by strong signals on adjacent frequencies. Obviously, then, for such applications as FM repeaters, and for metropolitan operation in general (where plenty of strong signals abound), selectivity would take precedence over broadband capability.

The two meter preamp described here represents what I feel to be a sound compromise with respect to bandwidth and gain. It is relatively broadbanded, but not so much as to allow tuning of the entire two meter band without some retuning. It is capable of resisting strong signals (above a millivolt) at adjacent 30 kHz points without desensitizing the receiver – a feature that qualifies it well for use with repeaters. The effective gain of this preamplifier is 14 dB; and the noise contribution is as low as the state of the art will allow.

The preamp owes its extremely low noise figure to the single HEP 802, a low-cost VHF junction-type field-effect transistor produced by Motorola for the hobbyist and experimenter market.[1] FETs in general have lower noise figures than ordinary bipolar transistors, and the junction FET has a significantly lower noise figure than the metal-oxide (MOSFET) type.

The circuit presented here -- designed, by the way, by Motorola engineers – uses the FET in a common-gate configuration. While common-gate amplifiers don't exhibit the sometimes astronomical gain that can be achieved with common-source or common-drain circuits, other factors make it an ideal choice for VHF applications. Chief among those "other factors" is the devilish *Miller effect*, the FET's traditional "most serious threat" to VHF applications. The Miller effect is the name applied to a FET's characteristic high-frequency feedback capacitance problem; as the frequency goes up, the gate-to-drain capacitance increases and actually appears *across* the amplifier, making the input impedance in effect a capacitive reactance.

Fortunately, while the Miller effect is horrendous with common-source amplifiers, and just plain terrible for common-drain configurations, it is a negligible consideration with the common-gate amplifier hookup. Clever engineers have developed methods for skirting the Miller effect, such as cascoding (with an "o" not an "a") the common-gate FET with a common-source type[2], but these add complexity – and complexity means expense. Considering the various tradeoffs, the most practical approach appears to be to settle for a little less overall gain than what is technologically possible in return for improved selectivity and a noise figure that is virtually incomparable.

Construction

The schematic diagram is shown in Fig. 1. As shown, the circuit represents a conservative use of components – a feature that is attractive from both the standpoint of economy and miniaturization. If you've worked with FETs at VHF before, you'll have no trouble with this excellent-performing circuit.

Just remember to keep the leads short; make good solder connections; don't overheat the FET leads (use sockets); and use effective shielding.

It's always a good idea to use printed circuit boards for projects like this, of course, but I didn't. The very good performance of my own unit serves as proof that a small piece of Vector board and point-to-point wiring with solid conductors can be as effective (and as small) as a printed circuit – and it *is* a darn sight less trouble.

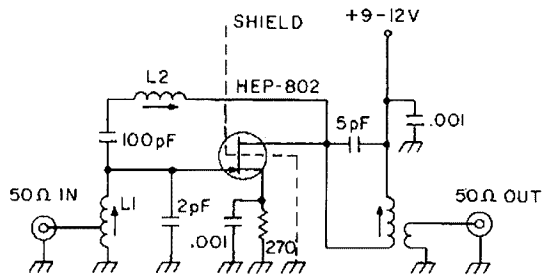

Fig. 1. This single-FET preamp offers an ideal compromise between selectivity and gain; not easily swamped by adjacent frequency signals, it will provide better than 14 decibels of signal improvement for fixed-frequency two-meter operation. Coil values are given in the text.

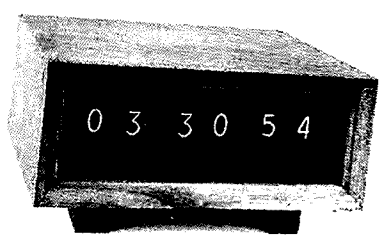
The preamp contains three coils wound on forms, plus one loop overwind. I used ceramic coil forms with 1/4" brass slugs. Inductor L1 consists of 5-1/2 turns of 26 gauge solid wire (tinned copper) wrapped on the slug-tuned form. This coil should be tapped 1-1/4 turns in from the ground end. Coil L2, also on a slug-tuned form, is 9-1/2 turns of 34-gauge wire. L3 is 5 turns of 26 gauge wire, and L4 is 1-1/4 turns of the same type of wire wrapped around the lower end of L3.

To avoid power-supply problems, I used a simple 9V transistor radio battery to operate my preamp. But for some applications, such as those involving use with a repeater, a battery would be impractical in spite of the preamp's low power consumption. The preamplifier's input voltage range, however, is broad enough to allow connection to a 12V source (rectified and filtered repeater filament supply, for example, or auto battery for mobile installations) with no circuit modifications.

Performance Checkout

If you plan to use the preamp with an AM receiver, you can adjust it for optimum performance in this fashion: first connect the antenna directly to the receiver and tune to a spot where there are no signals (but close to the frequency of maximum interest for you). If your S-meter has an adjustment

pot, set it to zero; if not, simply note the average no-signal reading. Then set the preamp's slug-tuned coils (L2 and L3) to about mid-position and apply power to the preamp. Disconnect the antenna from the receiver, place the preamp in line, and connect the preamp's output to the receiver antenna terminal. Slowly adjust the L2 slug for a maximum S-meter indication, then adjust L3. L2 is slightly more critical than L3, and it should be readjusted after each L3 adjustment. The S-meter reading should increase by at least two units. If broadband operation is desired, adjust L2 at the lower end of the frequency range you want and adjust L3 at the upper end. Then trim L2 for identical S-meter indication at both ends of the range.



If the preamp is to be used with a repeater, you'll probably have some test equipment on hand. If you have access to a signal generator and an ac voltmeter, you're in luck. Set the ac voltmeter to the decibel range (0–10V ac) and connect the leads to the speaker terminals. Turn on the receiver and open the squelch. Then adjust the receiver volume control for a reading of plus 20 dB on the meter. (If your ac voltmeter has no dB scale as such, adjust the receiver volume control for a reading of 7.8V on the 10V ac scale of a 20,000Ω per volt instrument.)

Connect a signal generator (properly warmed up for stability, of course) to the receiver without the preamp in the circuit, and increase the generator output until the meter reading drops to plus 14 decibels (6 dB quieting). This reading will be just under 4 volts on the 10-volt ac range. Recheck the generator for frequency stability, then insert the preamp, with power applied, between the receiver and the generator. Adjust L2 and L3 for minimum indication on the voltmeter – without readjusting the signal generator. If you've done a good job on the preamp, the adjustment operation should bring the meter reading down to well below zero decibels (less than 0.6 volt on the ac scale).

SOLID STATE

DIGITAL CLOCK

This product of space age technology computes and displays time of day to the exact second. High visibility Nixie tube readout. Encased in handsome oiled solid walnut case with matching base for desk or shelf mounting in any decor.

- **Silent solid state operation.**
- **Fractional second accuracy.**
- **Polaroid displays/red filter.**
- **Three special time settings**
- **Full year guarantee (made in USA).**
- **12 or 24 hour time display.**
- **TTL integrated circuits.**

Please specify 12 or 24 hour model. Send check or M.O. for $159, postpaid. COD's accepted with $30 deposit. Calif. residents, add 5% sales tax.

EXTRA CLASS LICENSE STUDY GUIDE

Questions & Answers Part IV

66. How are grounded-grid amplifiers used in electronic circuits? List some advantages and disadvantages of their use. Describe the input impedance characteristics of a grounded-grid amplifier.

A. Grounded-grid amplifiers are used in rf stages of both transmitters and receivers, but for different reasons. In receivers, the grounded-grid circuit eliminates the need for neutralization of triodes, and permits simple low-noise stages to be designed. The grounded-grid configuration also provides better voltage gain at higher frequencies than can be achieved in other configurations.

In transmitters, the grounded-grid circuit has become popular because of its low input impedance and ability to "feed through" excess power, making it ideal for bringing the output of a medium-power SSB transmitter up to the legal limit.

Advantages of the grounded-grid circuit include freedom from the neutralization requirement, relatively constant load upon the driving source, voltage gain comparable to that of a grounded-cathode circuit, and feed-through of excess driving power.

Disadvantages include the requirement for more driving power than required by more conventional circuits, the low imput impedance (which at times is an advantage), and the requirement that the preceding stage be modulated if the g-g stage is to be modulated.

Input impedance, as mentioned, is low; 50 ohms is an approximate typical value. Output impedance is high. The circuit has no current gain, and does not reverse signal phase.

67. What constitutes a parasitic antenna element?

A. A parasitic antenna element is any antenna element which is not electrically connected to a driving feedline, but operates by means of re-radiation of received energy.

68. What is the image-response of a receiver? How can it be reduced?

A. Every superhet receiver has the capability of responding to signals at two distinct input frequencies, for a single setting of the local oscillator. One input frequency is that which, when mixed with the local-oscillator signal, produces the i-f as the difference between input and local-oscillator frequencies, and the other is that which, when so mixed, produces the i-f as the difference between local-oscillator and input frequencies. That is, one is below the local-oscillator signal, and the other is above, by

the amount of the i-f. Only one of these two possible responses is the desired signal; the other is called the "image." The choice as to which is desired and which is image is made at the time the receiver is designed. The ratio between desired-signal strength, and image-signal strength (assuming equal-level input signals) is the image response criterion, and is usually expressed in dB of rejection of image. Image rejection can be improved by increasing selectivity of the circuits preceding the mixer, or by using a higher i-f, which separates the desired and image signals by a larger degree. Both remedies can be used.

69. What is a third party agreement? What countries have agreements with the United States?

A. A third party agreement is a special agreement between two nations, in which each agrees to permit its radio amateurs to handle messages for third parties in international communications between the two. In the absence of such special agreements, third party messages are prohibited.

At the time of writing, the United States had such agreements with at least 22 countries, all in the Western Hemisphere except Israel and Liberia. The list is subject to relatively rapid change, however, and current information should be checked for the exact list of countries at any specific time.

70. What effect will extending the low-frequency audio response of a signal have on the design of an SSB transmitter?

A. In a filter-type SSB exciter, extension of the low-frequency audio response requires redesign of the filter to have a wider passband, and may make carrier rejection more difficult. In a phasing exciter, achieving extended low-frequency response requires redesign of the audio phase shift networks, which are already a compromise. In either case, communications effectiveness is reduced, because the highest-power parts of the voice spectrum are in the frequencies below 300 Hz, while the parts producing intelligibility are above 300 Hz. Extending low-frequency response below 300 Hz thus limits the amount of power which can be devoted to the significant parts of the signal, while simultaneously making design and operation more difficult. For this reason most SSB rigs are restricted to 300–3000 Hz response.

71. List some different types of beam antennas.

A. Parasitic arrays, including the Yagi, the log-periodic, and as special cases the parabolic reflector and the corner reflector; Driven arrays, including the endfire, the Franklin collinear, the ZL Special, and the 8JK; and long-wire beams, including the rhombic, the vee-beam, and the simple long-wire. The term "beam antenna" includes all antennas having marked directional beam. Driven arrays can be composed of a number of parasitic arrays, and the elements of any driven array may themselves be complete driven arrays. Such complex beam systems are often used at VHF to achieve high power gain and extreme directionality.

72. What radioteletype transmitter operating deficiencies may be indicated by a decreasing antenna rf current during modulation of the final rf amplifier?

A. Decreasing antenna current during modulation, often called "downward modulation," may be due to several causes, depending upon the manner in which the modulation is applied. With conventional high-level plate modulation, downward modulation may be due to inadequate rf drive to the modulated stage, faulty tubes in the modulated stage, poor voltage regulation in the power supply (causing the modulator's power to be robbed from the modulated stage and thus causing a net loss in output), incorrect operating conditions in the modulated stage (particularly grid bias), or impedance mismatching between modulator and modulated stage.

With grid modulation the condition can arise as a result of attempting to get too much signal out at the carrier level, thus leaving room for upward modulation on peaks. This is improper adjustment of the loading. Lack of drive can also cause it, as can improper grid bias.

With screen modulation, downward modulation can result from improper loading, wrong grid bias, wrong screen voltage, inadequate drive, or insufficient modulator power. In all cases, the drive and loading conditions must permit the modulated stage to produce 4 times as much power at the

positive peaks of the modulating cycle as is produced at the carrier level, in order to achieve 100 percent modulation. If the stage is not capable of producing full output on positive peaks, downward modulation results because the indicated antenna current is the *average* over the modulating cycles, and with the peaks being clipped on the positive side, the negative peaks will reduce the average below the carrier level.

73. What improper operating conditions are indicated by the upward or downward fluctuation of a Class A amplifier's plate current when a signal voltage is applied to the grid? How can this be corrected?

A. Fluctuation of plate current when signal is applied to a supposedly Class A amplifier indicates only one thing: the amplifier is not actually operating Class A. This may be due to either of two possible causes: the input signal may be too large, driving the amplifier outside its intended operating range, or the grid bias is incorrect.

The remedy for overdrive is obvious – reduce the level of the input signal to that for which the stage is designed. Correcting improper bias is a bit more subtle.

If the plate current increases with signal, the stage has too great grid bias and it should be reduced. If the plate current decreases with signal, the bias is insufficient and should be increased. The correct bias is achieved when the plate current remains constant with application and removal of input signal.

At maximum drive and output, Class A power amplifiers show a slight increase in plate current as compared to the no-signal case, because of DC rectification in the output circuit. This should not be confused with the fluctuations referred to in this question.

74. What improper operating conditions are indicated by grid current flow in a Class A amplifier?

A. None, necessarily, because Class A amplifiers which depend upon grid current flow have been designed and operated. The conventional Class A amplifier, however, is designed to operate without grid current, and any grid current flow in such a circuit indicates overdrive. The chances are great that any such amplifier in which grid current is observed is not actually operating Class A because of the overdrive. See also question 73.

75. What may be the cause of a decrease in antenna current during modulation of a Class B rf amplifier?

A. The Class B rf amplifier should not be modulated directly; it operates properly only as a linear. If used as a linear, amplifying a signal to which modulation has been applied earlier, downward modulation indicates improper loading (too light) or an attempt to get excessive efficiency from the circuit. Downward modulation cannot occur with SSB.

76. What determines the skip distance of radio waves?

A. Skip distance depends upon two factors: the effective height of the reflecting layer, and the angle of reflection. These establish the altitude and one angle of a triangle, thus fixing the opposite leg's length (which is the skip distance). Both effective height and reflection angle in turn depend upon the frequency of the signal, and the condition of the ionosphere at the time.

77. How can parasitic oscillation be prevented?

A. By preventing the conditions (appreciable impedances at frequencies where the phase shift occurs) which permit them. This can be done by appropriate physical layout, choice of the proper types of bypass capacitors and rf inductors, and by application of parasitic suppressors to reduce gain at parasitic frequencies.

78. Give some proven methods of harmonic reduction in transmitters.

A. See question 61, Part III.

79. Describe briefly some well known types of antennas and antenna systems used by amateurs which do, and do not, reduce harmonic radiation.

A. Any non-resonant antenna will radiate energy at any frequency within the normal rf range equally well (or equally poorly). Thus it cannot reduce harmonics. Antennas which are themselves resonant, or which use resonant matching systems are selective and reduce at least some of the possible harmonics. Both types of antennas are widely used by amateurs.

One of the most well-known non-resonant antennas is the ordinary "long-wire" system. In its most common form, this consists of a length of wire of random length, insulated at one end and driven at the other. It is a common antenna for beginners' use because it is so simple to install. With luck, it can even be made to operate after a fashion. If the length is not some multiple of 1/4 wavelength at any specific operating frequency, the antenna is not resonant and so can radiate at any frequency. It therefore has virtually no reduction of harmonics.

The most common resonant antenna is the half-wave dipole. This consists of an electrical half-wavelength of wire, insulated at each end, split in the middle by an insulator, and driven in a balanced configuration at the center insulator ends of the two halves. It is resonant at every frequency for which the element halves are an odd multiple of 1/4 wavelength, and readily accepts power. Thus it will radiate at the 3rd, 5th, 7th, and other odd harmonics of the design frequency. It is also resonant at the frequencies for which the element halves are even multiples of 1/4 wavelength, but impedance at the feedpoint is inverted and it will not readily accept power from a low-impedance line. Thus it tends to reject energy at the 2nd, 4th, and all even harmonics of the design frequency.

Beam antennas achieve their directive qualities through careful phasing of the radiated energy, and this phasing is a function of frequency. Thus, most beam antennas reject all harmonics of their design frequency.

A popular class of ham antennas is the "all-wave" group which is designed to accept and radiate power at all ham frequencies using only one antenna system. Since the HF ham bands are all harmonically related, these antennas have had their harmonic-reduction properties carefully engineered OUT of them and consequently cannot adequately reject harmonics. Use of additional tuned circuits between transmitter and antenna system will restore selectivity and permit harmonic reduction.

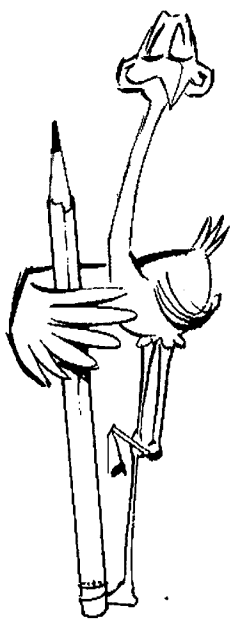
80. What must the value of an inductor be to cancel a capacitive reactance of 12.6 kilohms at an operating frequency of 2 Mc/s?

A. The inductor must have inductive reactance of 12,600 ohms at the same 2 MHz frequency, so its value must be 0.001 H (henry), or 1 mH (millihenry).

81. What is meant by "end effects" in an antenna? How can they be compensated for in half-wave antennas?

A. The end effect in an antenna is an apparent lengthening of the antenna element. That is, its electrical length is slightly greater than would be expected from its physical length, because of capacitance at the end of the conductor.

In half-wave antennas, end effects are compensated by making the physical length of the wire approximately 5% less than the desired electrical length would indicate.



82. What are the bandwidths normally used for A1, A3 (single and double sideband), and F3 (narrowband) type emissions?

A. Bandwidth of A1 signals depends upon keying speed. Most A1 signals occupy less than 50 Hz bandwidth. A3 with both sidebands, whether or not carrier is suppressed, requires at least 6 kHz and often occupies as much as 30 kHz. A3 with single sideband takes 3 kHz with carrier, and 2.7 kHz without. F3 in HF ham usage cannot exceed 6 kHz; at VHF it is not limited.

83. Describe briefly how an ac power supply produces a dc output voltage. Discuss the merits of using choke-input versus capacitor-input filters in power supplies. How does the leakage resistance of the capacitors affect the output voltage? Also, what is voltage regulation as related to power supplies?

A. The power supply uses a suitable transformer to convert the input ac to the appropriate voltage level, followed by a rectifier circuit which converts the ac to pulsating dc. Finally, a filter circuit smooths out the pulsations, yielding an approximation to "pure dc" as output. The quality of the approximation depends upon the quality of the filter.

A choke-input filter provides better voltage regulation than does the capacitor-input filter, but produces lower output voltage under light load conditions. The

PRINTED CIRCUITS

FAST — EASY with DATAK's

DIRECT ETCH SET

EASY—patterns rub down **directly on the copper board** and connect with rub-down lines or tapes supplied.
FAST—safe new etchants will etch a 2 oz. copper board in 30 minutes.
ACCURATE—±.002" print tolerance so parts and connectors mate with no errors.

Circuit Made With ER-1

COMPLETE ER-1 SET contains hundreds of dry transfer DIP, flatpack, TO-5, IC, and transistor patterns; 1/16" and 1/32" etch resist tapes; 4 copper clad boards; 1/4 lb. dry etch; tray and instructions. **$4.95 ppd.**

IN STOCK AT ALLIED AND OTHER DISTRIBUTORS

WRITE FOR FREE CATALOG listing this and many other dry transfer marking sets.

capacitor-input filter produces higher output voltage, but puts more strain upon the preceding components in the power supply. In consequence choke-input filters are normally used where high power is required, and capacitor-input filters are restricted to applications requiring comparatively low power (receivers and test equipment).

If a filter capacitor develops excessive leakage, (abnormally low leakage resistance), it will act as an additional load on the power supply thus reducing output voltage. It will also degrade filter performance. In most cases, such a situation is self-destructive; the abnormal current through the capacitor results in overheating, further weakening the capacitor, and the capacitor fails shortly.

Voltage regulation is a measure of the change in power supply output voltage between the no-load and fully loaded conditions, usually expressed as a percentage. The precise definition of voltage regulation varies, depending upon the reference book consulted. Thus a power supply which produces 105V dc at no load and drops to 95V dc at full load may have a voltage regulation of 95/105 (99.5%), 10/105 (9.5%), or 10/95 (10.5%), depending upon the definition used.

84. Compare silicon and vacuum tube diodes. What is meant by the "forward voltage drop" of a conducting silicon diode?

A. The silicon diode is a semiconductor device which operates upon the junction principle, while the vacuum tube diode operates upon the principle of thermionic emission. Thus most vacuum tube diodes require that the cathode be heated, while silicon diodes do not. Silicon diodes can conduct much greater current per cubic inch, but are far more subject to damage by improper operating conditions such as excessive reverse voltage or overheating.

Any diode is characterized by a "forward voltage drop." In a tube, this is the operating voltage required to move electrons across the cathode-to-plate distance, and ranges from 5 to 15 volts in most cases. In a silicon diode, it is the energy-level barrier between operating energy levels at the atomic level, and is approximately 0.65 volts (germanium diodes have a barrier of approximately 0.25 volts). The voltage drop is subtracted from the

applied voltage; if 5V dc are applied to a silicon diode, 4.35V dc will appear at the output.

85. What is push-pull amplifier operation?

A. Push-pull amplifier operation is a circuit arrangement in which a single stage contains two identical amplifiers, which are driven by input signals which are 180 degrees out of phase with each other. Outputs are similarly 180 degrees out of phase. If balanced input and output are available, no phase-inverting components are necessary. If input and/or output is to be unbalanced (single-headed), phase inversion is required. One of the simplest phase-inverting components is a transformer with a center-tapped winding. The center tap is the common return, and out-of-phase signals are either taken from or applied to the opposite ends of that winding. The other winding will combine the energy of both halves of the first, producing an unbalanced signal as required.

The push-pull or balanced circuit cancels out most even-order harmonics. It is widely used in industrial electronics under the name "differential amplifier" because any signal which is in the same phase at the inputs of both sides is cancelled out of the output.

86. For what purpose is a Q-multiplier used in amateur equipment? What major factors affect the Q of a coil? Of a circuit?

A. The Q-multiplier is usually used to increase the selectivity of a tuned circuit in a receiver; it may also be used to reject a specific signal frequency.

The Q of a coil is determined by the ratio of energy stored in the coil's magnetic field to energy dissipated in the coil's conductor, or the ratio of reactance to resistance. Thus size, material, and proximity to other components affect it.

The Q of a circuit is determined by the individual Q's of the circuit components, and again is defined as the ratio of energy stored to energy lost. Anything which causes loss of energy reduces the circuit Q; anything which increases its energy-storage capacity without increasing the energy loss will increase the Q.

87. How can the final amplifier of a transmitter be tested for self-oscillation?

A. See question 53, Part III.

88. How does a frequency converter operate?

A. Whenever two ac signals are simultaneously applied to a non-linear circuit, four ac signals are produced: the two original signals, a third signal having the frequency equal to the sum of the frequencies of the two original signals and the amplitude characteristics equal to the sum of the amplitudes of the two originals at each instant, and a fourth signal whose frequency is the difference of the original frequencies, also having amplitude determined by the instantaneous sum of the amplitudes of the originals. This action is known as mixing, modulation, demodulation, detection, or frequency conversion, depending upon what part of the communication chain contains it.

A frequency converter accepts an input signal at one frequency and converts it to an output signal at some different frequency by mixing it in a non-linear circuit with a local signal of constant amplitude. Since the local signal's amplitude is constant, the output signal's amplitude characteristics follow those of the input signal exactly. Output signal frequency is determined by the local signal frequency. Either the sum or the difference signal may be used for output. Tuned circuits eliminate the three unwanted signals from the output.

89. What visual observation within an operating vacuum tube's envelope would indicate that the tube is gaseous?

A. An intense blue glow in the space between plate and cathode of the tube, during operation, would indicate that the tube is gassy. A "gaseous" tube would be somewhat difficult to identify, being neither solid nor liquid (those being the three states in which matter can exist at normal temperatures); the ability to pass one's hand through it might be a valid indication of its being gaseous!

Questions based on Part 97 of the Commission's rules.

A. Obtain a copy of Part 97 and study it well, taking care to be familiar with those provisions which specify frequency bands and sub-bands, types of modulation, technical requirements, power limits, and administrative details such as license term, display of license, etc. . . . Staff

THE INDESTRUCTIBLE (BUT SENSITIVE) VOLTMETER

One piece of test equipment found in many hamshacks is the voltmeter. There are many voltmeter variations and each variation has advantages and disadvantages. Many of us have an idea of what we would like for the "perfect" voltmeter. Over the years, I have thought about my ideal voltmeter but never applied the elbow grease. Recently, the urge became strong and I actually built it. I can best describe my ideal voltmeter by describing the result of this urge. The voltmeter features a zero-center meter with a sensitivity of 1.33 MΩ/V for the 0.25–25V full-scale ranges. The input resistance is a constant 33.3 MΩ for the 25–750V ranges. Two current ranges of 0.75 and 7.5 μA were also included. The voltmeter can withstand most conceivable overloads without the slightest damage.

Theory

High input resistance is one very desirable characteristic of a voltmeter. Most panel meters are much too insensitive to provide the high input resistance; therefore, some kind of amplifier must be used. The common vacuum-tube voltmeter or transistor voltmeter, with which many of you are familiar, generally use the input–output or transfer characteristic of a tube or transistor to provide the amplification. The accuracy is affected by the inherent instability and nonlinearity of the tube or transistor as well as by power supply fluctuations. There is another way to obtain the required amplification without these problems. The technique (negative feedback) is not new and is used extensively in industrial instrumentation and analog computers.

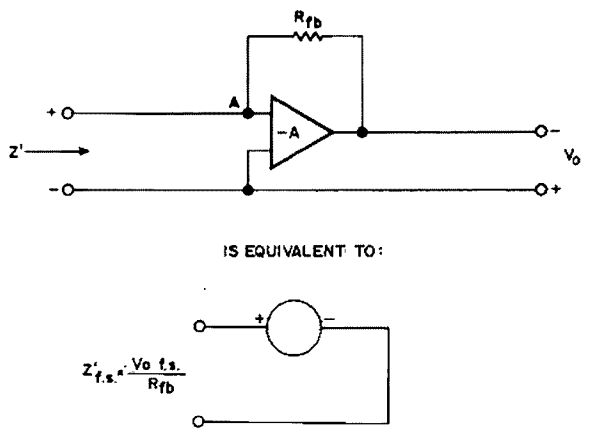

Fig. 1. Feedback amplifier equivalent circuit.

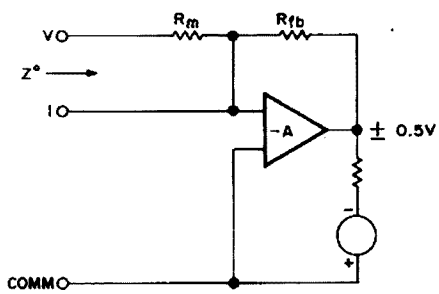
Negative feedback is used in many applications to reduce distortion and, in general, provide stable amplification. If sufficient feedback is used, such factors as transistor (or tube) variations and power supply instabilities have negligible effect on the overall gain of the amplifier. This type of circuitry is more complicated and, therefore, more expensive. In the past, the additional expense has eliminated this technique from the lower priced instruments and ham designs. Now, with the availability of good quality

economical transistors, all of us can afford this "sophisticated" technique.



One way to explain this technique is to think of the amplifier in Fig. 1 as a balancing device. If the amplifier has very high gain, a small voltage at the summing point (A) will appear at the amplifier output as a large voltage. Since the amplifier gain is negative (that is, a positive input produces a negative output and vice versa) the current through R_{fb} will oppose the input current. The opposing current will tend to drive the summing point back to zero voltage. In other words, the amplifier output opposes the input current until a balance or zero voltage is approached at point A. This balancing action will produce a current through R_{fb} which is very nearly equal to the input current. Even though summing point A is not directly connected to ground, the action of the feedback will maintain the voltage near zero. A more technical term for this point is a "virtual ground;" it appears like a ground point but actually isn't.

If the input voltage is always near zero voltage and the current through R_{fb} is equal to the input current, the output voltage (with reference to actual ground) is proportional to the input current. Applying Ohm's law, input current will be equal to the output voltage divided by the feedback resistance.

The advantages may not be apparent yet, but if we consider that the amplifier input can be a very, very small current, then the current through R_{fb} can also be very small. While the amplifier is balancing out this small current through R_{fb}, it can also supply a much larger current for the output voltmeter. The amplifier, feedback resistance, and output voltmeter can now be thought of as a sensitive current meter.

Without going into detail, a simplified example will demonstrate how feedback can reduce the effect of amplifier gain change on the overall circuit performance. If we assume an amplifier gain of 100 and output voltage of 1V, the amplifier input voltage will be −0.01V (remember the amplifier gain is negative). The actual voltage across R_{fb} will be 1.01V. Now, let the amplifier reduce gain by 50% or to a gain of 50. With this condition, the input voltage will be −0.02V when the output is 1.0V. Now the actual voltage across R_{fb} will be 1.02V. The voltage change across R_{fb} between the two conditions will be 0.01V or slightly less than 1% (0.01/1.01) change. Thus, a 50% change in amplifier gain produced only about 1% change in feedback current. Since all such things as instabilities, nonlinearities, and power supply variations are reflected in amplifier gain, the effect of these factors on the overall performance is reduced.

To sum up, the amplifier, feedback resis-

RANGE (VOLTS)	Z (μA)	Rm (ohms)	Rf (ohms)
±0.25	±0.75	333K	667K
0.75	"	1.00M	"
2.50	"	3.33M	"
7.50	"	10.0M	"
25.0	"	33.3M	"
75.0	2.25	"	222K
250	7.50	"	66.7K
750	22.5	"	22.2K

RANGE RESISTOR CALCULATION

Fig. 2. Range resistor calculation.

tance, and output voltmeter can be thought of as a sensitive current meter. The sensitivity, accuracy, and linearity is a function of the output voltmeter and feedback resistance and is relatively independent of amplifier variations. For the remainder of the voltmeter design, this combination can be replaced with an equivalent current meter. The input current sensitivity will be equal to the full scale output voltage divided by the feedback resistance.

Two methods are used to provide voltmeter ranges from 0.25 to 750V. As you will see, other ranges are easily calculated. For purpose of calculation of feedback resistors (R_{fb}), the voltmeter circuitry can be simplified as illustrated in Fig. 2. On the lower ranges, the current sensitivity is constant and the multiplier resistor (R_m) is changed with the range switch. The output voltage is the

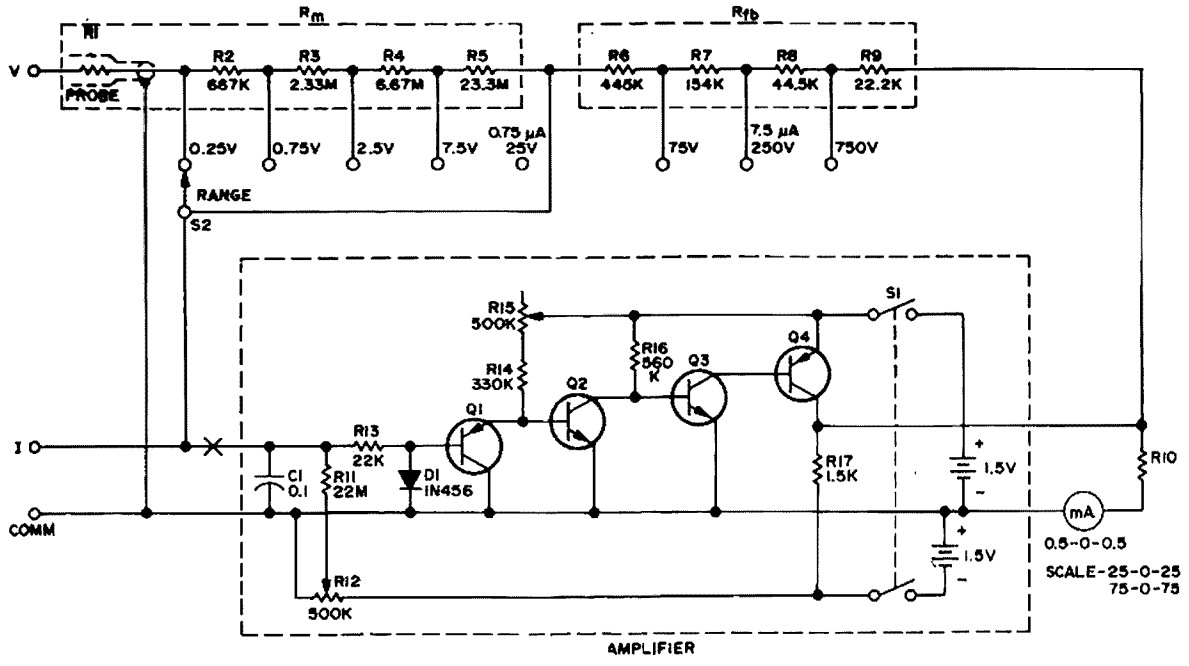


Fig. 3. Schematic.

same for all ranges. The output voltage swing determines the series resistance for the milliammeter. Full scale current for the lower ranges was selected at 0.75 μA. The feedback resistance, which also will be constant for the lower ranges, is equal to the full scale output voltage divided by the full scale current, or 0.5V divided by 0.75 μA. With this resistance (667 KΩ), we now have an input current sensitivity of 0.75 μA full scale. The multiplier resistances are calculated as if we had an 0.75 microammeter. For the 0.25V range, the resistance will be equal to 0.25 divided by .00000075 or 333,000Ω. The ranges up to and including the 25V range are calculated the same way.

For the higher ranges, the multiplier resistance is held constant and the current sensitivity is changed by selecting the feedback resistance. The multiplier resistance (33.3 MΩ) for the 25V range becomes the constant multiplier resistance for the higher ranges. As an example, on the 750V range the input current will be 22.5 μA (750/33,300,000). A new value feedback resistance must be calculated to provide this current sensitivity. With the same 0.5V output voltage, the feedback resistance will be 22.2 KΩ. All resistances values and the equivalent circuit are shown in Fig. 2.

Either method could be used for all ranges, but this combination was chosen as a compromise to maintain low input current on the lower ranges without requiring extremely large – and expensive – resistance values on the high ranges. Either procedure can be used to calculate feedback and multiplier resistances for other ranges. The feedback current should be selected within the amplifier design range of 0.75 to 50 μA.

A current function is also available as an added feature. For the particular ranges selected, only two ranges agree with the meter scales. The other ranges would be 2.25 and 22.5 μA, which can also be used, with a few mental gymnastics, to convert from one of the scales.

The voltage drop across the input used as

a current meter is very low. Since the amplifier gain determines how near zero the summing point is maintained, it also determines the voltage drop when the circuitry is used as a current meter. The amplifier voltage gain is about 100; therefore, when the meter indicates full scale (0.5V), the input voltage will be about 0.005V. Most milliammeters or microammeters will have 0.05–0.20V drop at full scale.

Circuit Description

Four direct-coupled silicon transistors form the amplifier portion of the voltmeter. The first two stages are operated at low collector voltage and current. In both cases, the base-to-emitter voltage (about 0.6V) of the following stage is also the collector-to-emitter voltage of the driving stage. This type of connection may appear strange, but it is a very legitimate application of silicon transistors. The last two stages are connected in a more conventional manner. This amplifier layout provides high current gain with a minimum of components.

The first two stages are operated at nearly equal collector currents and connected so that the base-to-emitter drops will cancel. The NPN (Q2) base voltage will be about +0.6V. When we connect a PNP (Q1) to this base, the PNP (negative) base-to-emitter voltage will tend to cancel the positive voltage of the NPN transistor. Actually, by adjusting the collector current ratio of the two transistors, the two base-to-emitter voltages can be made to cancel exactly. Similar reasoning will show that the temperature coefficient of the base-to-emitter voltages will also tend to cancel. The temperature coefficient defines the change in base-to-emitter voltage with temperature. This coefficient is the prime cause of instability in transistor dc amplifiers and is a cource of operating-point change in ac amplifiers.

The interconnection between the first two stages is also a current summing point or virtual signal ground. The current through R14 must divide and flow through either Q1 emitter or Q2 base. Therefore, any Q1 emitter current change will become a base-current change for Q2. The voltage at this point will *not* change. A similar situation occurs between the Q2 collector and Q3 base. Since Q3 collector is connected to Q4 base, it is obvious that the Q3 collector current changes are passed on to Q4. The result is an overall current gain of the amplifier which is the product of the current gains of the transistors. Even with the first two transistors operating at a low current gain (result of low collector current and voltage), the overall amplifier current gain is greater than 100,000.

The input offset current (current required for zero output voltage) is supplied by R11. The offset current adjustment is similar to biasing a single transistor, except in this case we are "biasing" a complete amplifier. An adjustment is shown in the schematic but the adjustment is not critical and fixed resistances could be used. When the amplifier is operating in closed loop (with the feedback connected) some offset current can be supplied through the feedback resistance without noticeable effect on the voltmeter performance.

Overload protection is supplied by R13, CR1, and the base-to-collector junction of Q1. As explained, the amplifier input is at zero potential during normal operation. If overloads are applied, the amplifier may saturate and not supply sufficient feedback current. Since the feedback current normally maintains the zero input voltage, loss of the feedback current will allow the summing point to stray from zero. If allowed to increase without limit, the input transistor could be damaged. The solution is to provide some current limiting (R13) and clamp the amplifier input with diodes. The positive excursions are clamped with CR1 and the negative excursions by the base-to-collector junction of Q1.

Meter current is also limited to a safe value by resistors R10 and R17. The output transistor (Q4) will either be cut off (positive input) or saturated (negative input) during overload situations. Maximum meter current is therefore limited to about 1.5 mA on negative inputs and 0.6 mA on positive inputs. Neither value will damage the meter movement.

The circuit is most susceptible to overloads when used in the current function. A couple of quick calculations will demonstrate the protection provided. Both the clamping diode (CR1) and the base-to-collec-

tor junction of Q1 will pass 100 mA for short periods without damage. As long as the diodes function, the amplifier and meter will be protected. Since the input current is limited by R13, the input voltage would be 2.2 kV with a diode current of 100 mA. The R13 wattage rating limits continuous overloads to about 100V.

When the voltmeter function is used, higher overload voltages are easily accommodated. On the 0.25V range, the total series resistance is 355 KΩ. Now the half-watt resistor rating limits the continuous overload to about 350V and the diode current will protect up to "3.5 kilovolts" – hardly conceivable!

Higher-wattage resistances could be used but most of us would not subject the voltmeter to continuous overloads. The worst that could happen from a continuous overload would be to burn up either R1 or R13. I don't think it is possible to damage a transistor or the meter with conceivable overloads. By the way, one point to think about – how many 0.75 μA meters are protected from continuous overloads up to 5 mA and terminal voltages of 100V? How many 0.25V meters are protected against 350V continuous or momentary kilovolts?

The feedback network completes the voltmeter circuitry. For any one range only two resistance values are required. The capacitor (C1) provides high-frequency attenuation to prevent amplifier oscillation. The range switching is not quite conventional. A single-pole switch is used to select the proper multiplier and feedback resistance. The switch actually shorts out the unused portion of the resistance string.

Construction

The layout is not critical and is left up to the builder. Standard solid-state construction methods must be used – watch the heat when soldering! The ranges selected may seem strange but fit very nicely with a standard 50-division meter scale. The meter I used was a 1.0 mA unit I readjusted to a 500-0-500 μA span. I removed the numbers on the original face with an eraser, leaving the scale markings. The new numbers were hand-lettered on the face. On the 50-division scale, the selected ranges require one unit per minor division on the 25-0-25 scale, with 5, 10, 15, 20 and 25 at major division. The second scale requires 3 units per minor division with 15, 30, 45, 60 and 75 at the major divisions.

Feedback and multiplier resistances (R1–R9) must be accurate if the precision of the voltmeter is to be maintained. I selected resistances from carbon resistor stock using a Heathkit impedance bridge. The builder who does not have access to measuring equipment can buy 1% precision resistors from a parts house. I believe it is possible to buy 1% resistors, a 2% panel meter, and assemble this voltmeter with 3% or better error without further calibration. This demonstrates the beauty of the feedback amplifier – final accuracy is only dependent on the resistors and meter used.

The voltage probe is constructed of shielded cable with one multiplier resistor (R1) mounted in the tip. The shielding reduces ac pickup which might cause nonlinear operation of the amplifier, and the tip-mounted resistor reduces capacity loading of the circuit under test.

All components are described in the parts list. Most of the components are not critical as long as the noted characteristics are met. The transistors are not critical with regard to voltage rating or frequency response but must have low leakage and some current gain at low current (around 3 μA collector current). The transistors specified have been used successfully, although many other types are available which should be satisfactory. The suggested precision resistor series is the most economical that could be found which is readily available.

The final performance of the voltmeter can be no better than the quality of the meter. A quality movement can be used to advantage if the wallet can afford it. Some of the new taut-band meters which are very rugged would be a good choice. Other movement sensitivities can be used with some circuit modification. First, the scale divisions must be considered. The ranges in this voltmeter are based on a 50-division scale. Other scales will require some rearrangement of the ranges. One rule to follow when selecting ranges and scales is: Minor divisions should always represent

whole numbers (a minor division should represent either 1, 2, 3, etc., but not 1.5, 1.33, or other noninteger values). One exception to this can be 2.5, which sometimes works out reasonably well. As a last resort, you can always draw a second scale along the original scale.

A different meter sensitivity also requires different meter resistors (R10) and load resistor (R17). The amplifier output is ±0.5V full scale, so R10 must be chosen to make the selected meter read (with the resistor in series) 0.5V full scale. This calibration can be either calculated (if the meter resistance and sensitivity is known) or a portion of the series resistance can be replaced with a Trimpot. After the meter is completed, the voltmeter can be calibrated to a known voltage with the Trimpot adjustment. Following this procedure for the described voltmeter, R10 should be replaced with an 887Ω 1% resistor and a 100Ω Trimpot (assuming the meter resistance is less than 100Ω). This procedure is also better for the perfectionist who would like to get the most accuracy from his voltmeter.

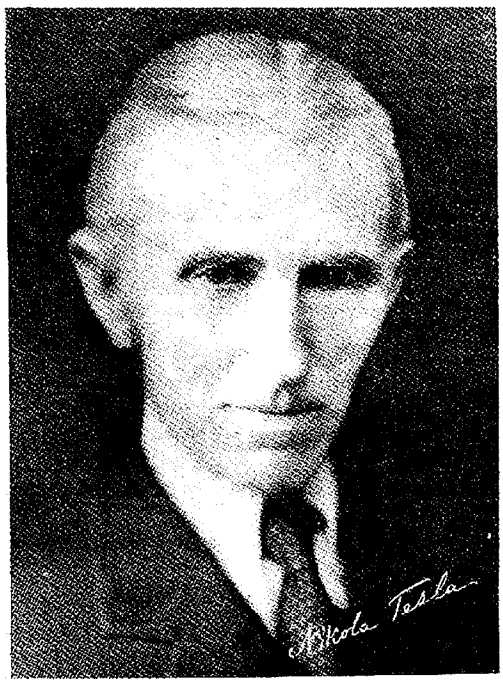
The load resistor (R17) which also determines battery current should be changed to agree with the meter sensitivity. It should be 1.5 times the total resistance of the meter and the series resistor (R10). With a little investigation, you will find that the battery current, with no input to the voltmeter, will be twice the full-scale meter sensitivity. With the described voltmeter, the battery current will be about 1.0 mA. If a more sensitive meter is used, the battery can be reduced proportionately. As an example, if a 50-0-50 μA meter is used, the battery current would be 100 μA and two RM1 mercury cells (1000 mA-hr) would last for about 10,000 hours, or one year of continuous operation. With this meter sensitivity, R17 would be 15 KΩ and R10 plus the meter resistance would be 10 KΩ.

The described voltmeter should operate continuously for about 6 months with two size D flashlight batteries. Therefore, the off-on switch is optional, depending on how often you would like to change batteries. Even with small batteries, the voltmeter can be left on occasionally without running the batteries down.

Checkout

Do not connect the range switch to the amplifier as indicated by the X on the schematic. Now, with the power applied and R12 adjusted for zero voltage on the arm, the meter should be pegged. Slowly adjust R12 and the meter should swing down-scale. Try to adjust for an on-scale meter reading. It isn't necessary to be very accurate since the amplifier feedback will take care of considerable misadjustment. If the meter doesn't swing down-scale, R11 can be decreased to about 5 MΩ or a different transistor tried for Q1.

To adjust the voltage offset, short the amplifier side of X to ground. Adjust R15 for a midscale meter reading (within 5 divisions of zero). Again, it isn't necessary to be very accurate. This completes the initial adjustment of the voltmeter. The wiring can be completed by connecting the range switch. The voltmeter is now operational. If a Trimpot was added to the meter resistance (R10), now is the time to apply a known voltage to the input and adjust the pot for the correct meter reading. These adjustments should not change in the future. I actually selected fixed resistances for my voltmeter and no change has been apparent in over a year of operation. *Do not* attempt to readjust R12 and R15 with the switch connected. The effect of these adjustments is not very noticeable except under detailed examination.



Conclusion

Several voltmeters have been built with good results. One model was subjected to temperature stability tests from −20 to +140°F with less than 2% of full-scale drift in calibration and zero reading. The basic circuit has also been used for a dc oscilloscope amplifier.

The feedback and instrumentation techniques that have been presented are also useful in other ham applications. This circuit can be used for other sensitive current measurements in conjunction with field strength meters and swr bridges. Other applications will become more apparent as the circuit capabilities are better understood.

Commander E. J. Quinby, USN (Ret.)

WHO WAS TESLA?

Ask any electrical engineering student today to tell you something about Tesla, and you are likely to get a blank stare. Or the counter-question: "Who *was* Tesla?" It seems preposterous that our educators should have ignored entirely the founder of our ac age, but such is the fact. Something should be done about our technical education system.

Born July 9, 1856 in the village of Smiljan in what is now Yugoslavia, Tesla rose from relative obscurity to a top position in the scientific world. He became a millionaire at 32 through his important inventions, only to fade later into obscurity, and died penniless.

His father was a clergyman. His mother, though she never learned to read and write, was known in the community as an inventor of domestic labor-saving devices, and it is to her that Tesla attributed much of his inventive genius. The young Tesla, opposing his father's urging to study for the ministry, insisted on a career in engineering. His mother encouraged him. He attended the polytechnic school at Graz, specializing in physics and mathematics, and continued his education at the University of Prague. There he took a course in foreign languages, so that he could read the foreign technical literature. He became proficient in English, French and Italian, in addition to the German with which he was already familiar, and of course, his native Serbian.

Finishing at Prague in 1880, he took a post-graduate course in Budapest, where he debated the merits of alternating current with his professors. He then went to work for a Paris telephone company, where he acquired considerable experience with dc dynamos and motors. While there he invented regulating and control devices to protect the rotating machines he served.

Electrical Industry Was Limited

In those early days, direct current was universally acknowledged to be the only practical medium for generating, transmitting and applying electricity for heat, light or power. But dc resistance losses were so great that a power plant was needed for every square mile served. Early incandescent

lamps, glowing none too bright on 110 volts even close to the power plant, became pitifully dim on the power that dribbled from the lines less than a mile away. And everyone believed that motors could run only on dc. An alternating current motor was considered an impossibility.

This was the picture when, in 1884, young Tesla stepped off a ship in New York, his head full of ideas, and four cents in his pocket. His experience had convinced him that the commutator in direct current motors and dynamos was an unnecessary complication, causing endless troubles. He realized that the "dc generator" actually produced ac, which was rectified by the commutator into a series of waves, all flowing in the same direction through the external circuit.

Then, to get this dc to produce rotary motion in a motor, the process had to be reversed. The armature of each electric motor was equipped with a rotating switch (commutator) that changed the polarity of its magnetic poles just at the right instant as it revolved, to supply ac to the motor.

The Inspiration

To Tesla, this was sheer nonsense. It seemed logical to eliminate the commutator at both generator and motor, and use ac through the whole system. But no one had ever built a motor that could operate on alternating current, and Tesla struggled mentally with the problem. And one day in February, 1882, while strolling with a classmate named Szigetti in a Budapest park, he suddenly blurted out: "I've got it! Now watch me reverse it!" At that moment he had visualized the rotating magnetic field, which would revolutionize the whole electrical industry. He saw the magnetic pull racing around the stationary field (stator) of his motor while the armature (rotor), attracted by the moving field, chased around after it faster and faster until it was revolving at the same rate. He would need no switching to the rotating element – no commutator!

Subsequently he worked the whole alternating current electrical system out in his mind – including alternators, step-up and step-down transformers for economical transmission and delivery of electric power, and ac motors to supply mechanical power. Impressed by the wealth of available water power going to waste around the world, he visualized the harnessing of this great supply with hydro-electric plants capable of distributing the power to where it was needed. He startled fellow-students in Budapest by announcing: "Some day I will harness Niagara Falls."

Discouraged by Edison

The opportunity and fortune Tesla sought in the promised land did not come easy. When he met Edison, then actively engaged in developing a market for his incandescent lamp through his pioneer Pearl Street plant in New York, Tesla launched with youthful enthusiasm into a description of his alternating current system. "You are wasting your time on that theory," the great man told him, dismissing the idea promptly and finally.

For a year, the tall, gaunt Yugoslav struggled to keep from starving in this strange land. At one point he dug ditches to make a living. But the foreman of the Western Union ditch-digging project on which he was working listened to the visionary descriptions of new electrical systems that Tesla related during lunch hours, and introduced him to a company executive named A. K. Brown. Fascinated by Tesla's vivid plans, Brown and an associate decided to take a flyer. They put up a limited amount of money, with which Tesla set up an experimental laboratory at 33-35 South Fifth Avenue (now West Broadway). There Tesla set up a complete demonstration of his system, including generator, transformers, transmission line, motors and lights. He worked tirelessly, and without drawings; the plans for every detail were indelibly etched in his mind. He even included two-phase and three-phase systems.

Professor W. A. Anthony of Cornell University examined the new ac system, and promptly announced that Tesla's synchronous motor was equal in efficiency to the best dc motors.

Alternating Current Arrives

Tesla then attempted to patent his system under a single comprehensive patent cover-

ing all its components. The Patent Office would not approve the all-in-one application, insisting on separate applications for each important idea. Tesla's applications, filed in November and December of 1887, resulted in the granting of seven U.S. patents in the next six months. In April, 1888, he filed for four more patents, covering his polyphase system. These too were promptly granted, as were 18 more U.S. patents later in the year. These were followed by numerous European patents. Such an avalanche of patents, so promptly issued, was without precedent, but so completely novel were the ideas -- so completely absent was any element of interference or "anticipation" – that the patents were issued without a single challenge.

Meanwhile Tesla staged a spectacular lecture and demonstration of his ac system – single phase and polyphase – at a meeting of the AIEE (now the IEEE) in New York. The engineers of the world were made aware that the limitations on electric power transmission by wire had been removed, opening the door to tremendous expansion.

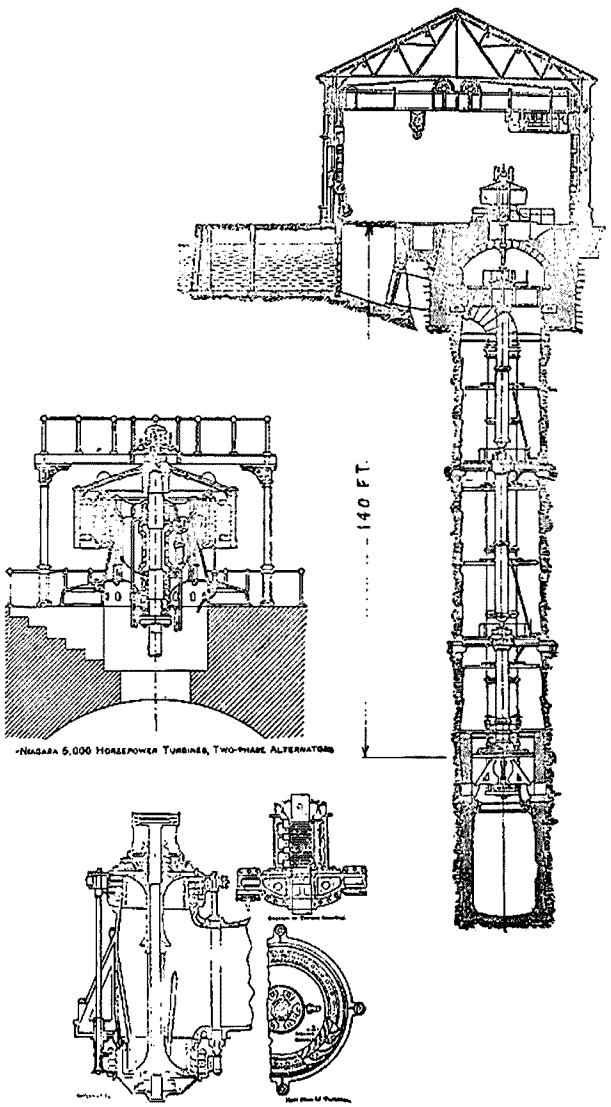
But who would adopt this obviously better system? Certainly not the established Edison-General Electric organization – it would have made their whole investment obsolete. Apparently Tesla was stuck – with no market, no customer for what he had to offer.

It was at this moment that George Westinghouse walked into Tesla's laboratory and introduced himself. Tesla was then 32 years old, Westinghouse 42. Both were capable inventors, accomplished engineers and electrical enthusiasts. Westinghouse listened to Tesla's explanations watched his demonstration, and quickly made up his mind.

"I will give you one million dollars cash for your alternating current patents, plus royalties," offered Westinghouse.

"Make that royalty one dollar per horsepower, and it's a deal," replied Tesla, without apparent excitement.

As simply as that, the two men arranged the historic deal and shook hands on it.



Tesla had arrived! But he was not a man to forget those who had placed their faith in his ideas, and promptly signed over his million-dollar fee to Brown and his associate, who had financed his laboratory. Although the backers of Westinghouse later forced him to get a release from Tesla on the dollar-per-horsepower part of the agreement, such was the friendship that had developed between the two men that an amicable settlement was quickly reached. Tesla relinquished the royalties that would have supported him and his research efforts for the rest of his life.

The phenomenal success of the Westinghouse ac systems across the nation made it clear to General Electric engineers that they would have to get a license from Westinghouse if they were to keep up in the rapidly expanding electrical industry. The license negotiated at a handsome fee – was a feather in Tesla's cap; he distinctly recalled Edison's statement that there was no future in alternating current and that experimenting with it would be a waste of time.

A Dream Realized

In 1890, the International Niagara Commission began trying to determine the best way of using the power of Niagara Falls to generate electricity. The scientist Lord Kelvin was appointed chairman of the Commission – and he immediately announced that a dc system would obviously be best! It was not easy to challenge this world-famous authority, but he eventually came to realize that if power were to be transmitted even the 26 miles to Buffalo, ac would be necessary. So it was finally decided to use Tesla's system and generate ac with massive water turbines. Bids were invited by the newly formed Cataract Construction Co. in 1892. Westinghouse won the contract for the ten 5,000-HP hydro-electric generators, and General Electric the contract for the transmission system. The whole system – the line, step-up and step-down transformers all followed Tesla's two-phase design. He designed the big alternators with external revolving fields and internal stationary armatures, to minimize the weight of the moving members.

This historic project created a sensation, for nothing of this magnitude had been

One of the 5,000 h.p. Niagara Falls units, with detail at left. Upper drawing shows the hollow drive shaft that goes through the stationary armature to rotate the field, which hangs outside and around the armature.

attempted at the time. The ten big 2,250-volt alternators, revolving at 250 rpm and delivering 1,775 amperes each, produced an output of 50,000 HP or 37,000 kW, 25 Hz, two-phase. The rotors were 10 feet in diameter and 14 feet long (14 feet high in these vertical generators) and weighed 34 tons each. The stationary members weighed 50 tons each. The voltage was stepped up to 22,000 for transmission.

Remote Radio Control

Tesla's pioneering in the realm of radio ("wireless" as it was then called) went further than Morse code communication. In 1898 he staged a spectacular demonstration of remote control without wires at the original Madison Square Garden, New York City. The first annual Electrical Exhibition was then in progress, and in the center of the vast area where Barnum & Bailey's circus usually performed, he had a large tank constructed and filled with water. Afloat on this small lake he had a 3-foot-long iron-hulled boat, with its mast supporting an antenna. Inside the hull was a radio receiver and an assortment of electric motors, driven by storage battery, to perform various "ship" functions.

From the opposite end of the auditorium, Tesla put the vessel through a variety of maneuvers, including sailing forward, steering left and right, stopping, reversing, and lighting the lights in its rigging in response to audience requests. The impressive demonstration of course "stole the show" and made the front page of the daily newspapers. But how many dreamed that one day, using these radio-remote-servo-control principles, we would land some of our citizens on the moon?

Mathematical Wizardry.

Tesla's mathematical genius stood him in good stead in the design of the items of ac equipment that Westinghouse and GE undertook to manufacture. (In his early student days, he solved complex problems in his head, without pencil and paper). His teachers suspected him of cheating, and put him to conclusive tests. Young Telsa, it developed, had memorized whole logarithmic tables!) The now established frequency of 60 cycles per second (Hz) stems from Tesla's mental calculations, which convinced him that it was the most practical frequency for commercial use. At higher frequencies, ac motors would become inefficient; at lower frequencies they would require too much iron. Lights would also flicker at low frequencies.

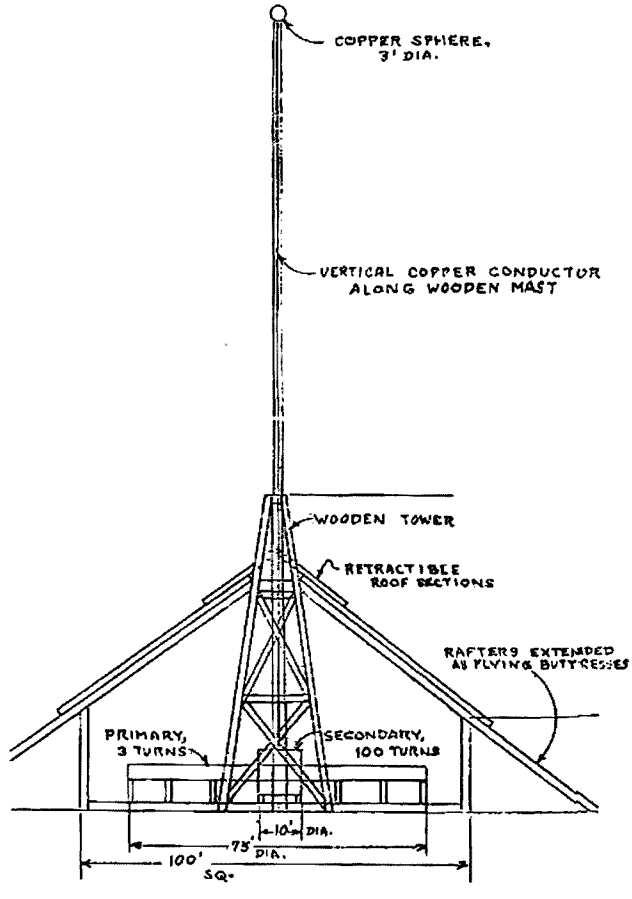
Though the original Niagara Falls plant was designed for 25 Hz to accomodate the limitations of the early Westinghouse turbine generators, subsequent expansion included conversion to 60 Hz. Today this Niagara power is transmitted all the way to New York City, 360 miles away, and at times is fed over the Northeast power grid for much greater distances. (When Tesla arrived in

New York, the limit for efficient power transmission was less than a mile!)

High Frequency Pioneering

During his investigations into the unknown realms of high voltage and high frequency, Tesla adopted a most sensible practice. When handling high-voltage apparatus, he always kept one hand in his pocket. He insisted that all his laboratory assistants take this precaution, and to this day it is always employed by sensible experimenters around potentially dangerous equipment.

Tesla's explorations in higher frequencies and in the field of incredibly high voltages paved the way for modern electronics, although the word had not yet even been coined. With his unique high-frequency transformers (Tesla coils) he showed that he could actually pass millions of volts harmlessly through his body to glow-tube lamps held in his bare hands. They would light up to full brilliancy from the high-frequency, high-voltage currents. In those early days he was actually demonstrating neon-tube and fluorescent tube lighting!



Tesla's experiments up and down the frequency scale sometimes led him into unexplored regions. Studying slow mechanical or physical vibrations, he caused a virtual earthquake in the vicinity of his new laboratory on Houston St. His mechanical oscillator, approaching the natural period of the building itself, threatened to tumble the old structure. Furnishings in the police station over a block away began to dance around mysteriously as Tesla confirmed his mathematical theories of resonance, vibration and "natural periods."

World's Most Powerful Transmitter

Investigations of high-voltage and high-frequency electrical transmission led Tesla to construct and operate the world's most powerful radio transmitter, on a mountain near Colorado Springs. Around the base of a 200-foot mast, he built a 75-foot diameter air-core transformer. The primary was only a few turns of wire. The secondary within it was 100 turns, 10 feet in diameter. Using power from a generating station several miles away, Tesla created the first man-made lightning. Deafening bolts 100 feet long leapt from the 3-foot copper ball at the top of this mast. The thunder was heard as far away as the horizon. He was using voltages of the order of 100 million – a feat not to be equalled for half-a-century.

Tesla burned out the power plant generator with his first experiment but repairing it, continued his experiments until he was able to transmit power without wires for a distance of 26 miles. At that distance he was able to light a bank of 200 incandescent lamps – a total of 10 kilowatts. Fritz Lowenstein, later to become famous for his own radio patents, witnessed this spectacular accomplishment, as Tesla's assistant on the project.

In 1899, Tesla had somehow spent the last of the money he got from Westinghouse for his ac patents. Colonel John Jacob Astor came to his financial rescue, and put up the necessary $30,000 for the Colorado Springs experiments. Now this money was also gone, and Tesla returned to New York.

The 100-million-volt transmitter, power from which lighted 200 50-watt lamps at a distance of 26 miles.

Enter J.P. Morgan

In New York, Tesla was prevailed upon by his friend Robert Underwood Johnson, editor of *Century* magazine, to write a feature story describing his accomplishments at Colorado Springs. But the story Tesla turned out proved to be an involved discourse on the subject of philosophy and 'the mechanical process of humanity." Although of the highest literary quality, the treatise said little about the powerful transmitter at Colorado Springs. Johnson had to return the manuscript three times before getting some coverage of the subject he had requested.

In the end, the article was published under the title, "The Problem of Increasing Human Energy.'' It created a sensation when it appeared in print. One of the readers who was deeply impressed was John Pierpont Morgan, who had financed the General Electric Co. in its pioneer dc days, and more recently its part of the Niagara Falls project. Morgan was fascinated by the genius of Nikola Tesla, by his spectacular accomplishments and his winning personality. Tesla soon became a regular guest at the Morgan home. Impeccably dressed, always the polished gentleman with European manners and cultured speech in several languages, Tesla became a favorite of New York and Newport society. Many prominent matrons regarded him as a "good catch" for their daughters, but Tesla insisted that there was no room in his life for women and romance -- that they would interfere with his research efforts.

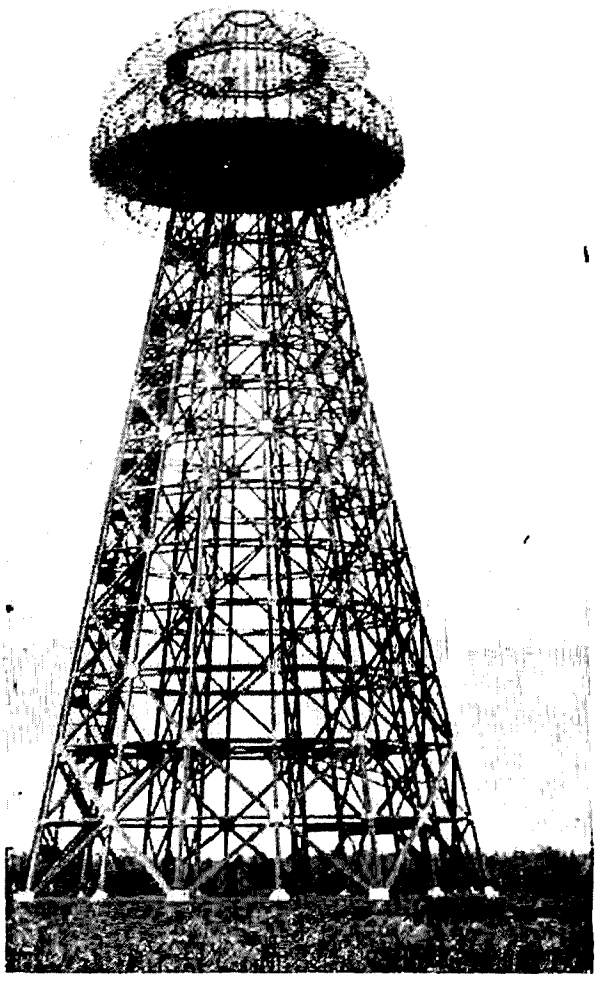
Historians differ on what motivated Morgan to finance Tesla's next big project. Some believe that he was genuinely interested in the wireless transmission of power. Others argue that – in the light of subsequent developments – it seems obvious that Morgan's interest was in getting control of Tesla and his achievements to protect the Morgan investments in the electrical industry.

Finding that Tesla was broke again, Morgan agreed to underwrite Tesla's project of transmitting electric power without wires. In 1904, Tesla acknowledged in *Electrical World and Engineer*: "For a large part of the work I have done so far I am indebted to the noble generosity of Mr. J. Pierpont Morgan."

From this alliance sprouted the fantastic "world-wide-wireless" tower on Long Island.

World Wide Wireless

The strange structure that slowly rose near Wardenclyffe, in the hilly portion of Long Island, mystified all observers. Resembling nothing so much as a huge mushroom, except that it was not solid, it had a lattice-work skeleton, broad at the base and tapering toward its 200-foot top. There it was capped by a 100-foot diameter hemisphere. The structure was made of stout wooden members joined by copper gussets bolted to the wood with sturdy bronze bolts. The hemispherical top was draped over its upper surface with copper mesh. There was no ferrous metal in the entire structure.



The famous architect Stanford White became so interested in the project that he did the design work without charge, assigning one of his best designers. W.D. Crow, to the task.

Tesla commuted daily to the construction from his quarters in the old Waldorf-Astoria Hotel on 34th St., riding the streetcars to the East 34th St. ferry, then the paddle-wheel steam ferry to Long Island City and the Long Island Railroad to Shoreham. The railroad's dining service prepared special meals for him so that his supervision of the project would not be interrupted.

When the 100-foot square brick power plant was completed near the base of the big tower, Tesla began moving his Houston St. laboratory into the structure. Meanwhile, annoying delays were encountered in the manufacture of the radio-frequency generators and their driving motors. Several glass-blowers were busy fashioning special tubes, the design of which still remains a mystery.

The Prophet Tells of The Future

Meanwhile, Tesla issued a descriptive brochure that revealed his far-reaching insight into the future of the great industry that at that time (1904) was limited to dot-and-dash telegraphy. That document has persuaded many that the man was actually clairvoyant. He announced that the World

Not all the facts on the mysterious Long Island tower were ever known. Some believe that it was intended to transmit at low frequencies, "shaking the earth" to send signals to distances then believed impossible. Tesla foresaw a complete modern type of service, but never stated how large an area be intended to cover. But, he called it the World Wide Wireless System!

Wide Wireless system was being prepared to provide a variety of facilities, including:

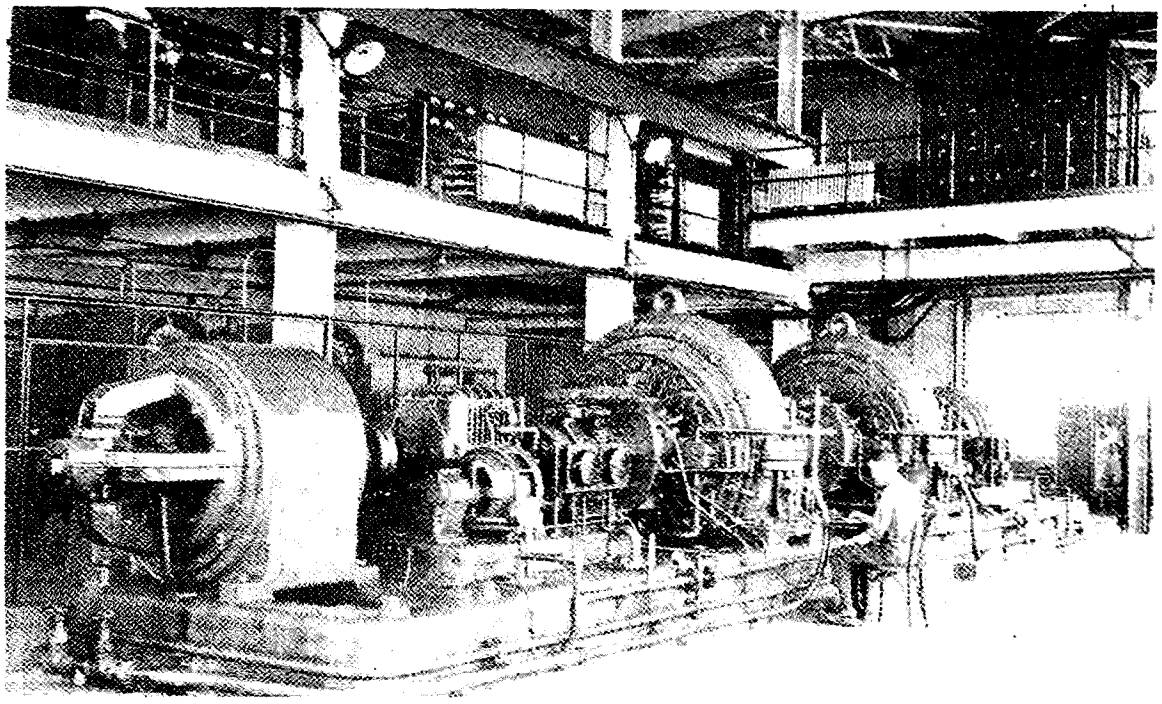
Telegraph Communication, Telephone Communication, News Broadcasting, Stock Market Quotations, Aids to Navigation, Entertainment and Music Broadcasting, Accurate Time Service, Facsimile, Telephoto and Teleprinter services.

Tesla was describing the Radio City of the future, which he actually lived to see come into existence!

Morgan's Support Ends

In *Electrical World and Engineer* of March, 1904, Tesla revealed that the Canadian Niagara Power Co. had offered him inducements to locate his wireless power transmission project at their plant, and that he proposed to employ those facilities to distribute 10,000 horsepower at a potential of 10 million volts.

The Niagara project never materialized, but may have had some influence on the fate of the spectacular Long Island project. For reasons that have never come to light, J.P. Morgan had a change of heart, and Tesla's financial fountain suddenly went dry. At first Tesla refused to believe that Morgan would not arrange for the nearly finished job's completion, but Morgan's withdrawal was abrupt and final. Historians of the industry wonder why. Did Morgan lose patience? Did engineers of high repute convince him that Tesla's visions, so openly revealed in the brochure, were nonsense, and that he was wasting his money on a hopeless dream? Did he suspect that Tesla was diverting time and money to the Niagara project? The facts will probably never be known.



Brainless Desecration

During World War I much senseless desecration was perpetuated in the name of national defense. For some strange reason (or lack of reason) it was decided that Tesla's spectacular tower at Wardenclyffe, Long Island jeopardized the safety of the United States, and must be destroyed. After vain attempts to topple the lofty structure by attaching cable to it and trying to drag it off balance, it was finally capsized by dynamiting its foundations. Even then, the tower did not collapse nor disintegrate. It simply lay intact on its side, and was finally dismantled piece by piece.

But why did this structure have to be dispensed with? Many taller objects closer to New York City – including the Ramapo Mountains were allowed to remain intact!

The Radio-Frequency Alternator

As early as 1890 Tesla built high-frequency ac generators. One, which had 184 poles, produced a 10 kHz output. He later produced frequencies as high as 20 kHz. More than a decade was to pass before Reginald Fessenden developed his rf alternator, which had an output of 50 kW. This machine was scaled up to 200 kW by

"The Author as a Young Man," E. J. Quinby watches over the great 200 KW alternators at WII, New Brunswick, N.J.

General Electric, and put on the market as the Alexanderson alternator, named after the man who had supervised the job, and who had constructed some of Fessenden's earlier alternators.

When it appeared that British interests (already in control of most of the world's cables) were about to acquire the patents for this machine, the Radio Corporation of America was organized, at the urgent suggestion of the United States Navy. The new company was formed in 1919, around the Marconi Wireless Telegraph Co. of America, and the powerful but inefficient Marconi spark transmitters were replaced by the highly successful rf alternators. The first one was installed in New Brunswick, N.J. at station WII. It produced a 21.8 kHz signal at 200 kW, and handled commercial business previously the exclusive domain of the cables. This was the first continuously reliable trans-Atlantic radio service.*

*Dr. E. Stuart Davis, of the National Telegraph Office (Museum) in Union, N.J., happily reports that one of these giant alternators has been preserved in the Smithsonian Institute, where it stands as a monument to Tesla's pioneering. Fessenden's perservance, Alexanderson's development and Sarnoff's leadership. This one originally served at Trans-Atlantic Transmitter Station WSO at Marion, Mass.

The writer, as the most junior of the junior engineers on the project, struggled like the rest to keep the first machine running until the next was ready to provide relief. So well did these alternators perform that a whole battery of them was ordered, to be installed at Radio Central, Rocky Point, L.I., almost within the former shadow of Tesla's tower.

Thus Nikola Tesla's World Wide Wireless dream was fulfilled some three decades after he initiated the project and right where he started it, using the type of transmitter he devised.

Radar and Turbines

Tesla continued active research in many fields. In 1917 he suggested that distant objects could be detected by sending short-wave impulses to them and picking up the reflected impulses on a fluorescent screen. (If that doesn't describe radar, what does?) He described cosmic rays 20 years before other scientists discovered their existence.

At various times up to 1929, he devoted his attention to a "bucketless" high-speed turbine for steam or gas Friction between the increasingly irascible Tesla and some of the engineers and assistants cooperating with him on tests at the Edison Waterside power

plant and in the Allis-Chalmers factory did not help his cause, but many respected engineers today agree that we have not heard the last of the Tesla turbines with the smooth rotor discs.

As the years passed, less and less was heard from him. Occasionally, some reporter or feature writer would look him up and manage to get an interveiw. His prophecies became increasingly strange and involved, inclined toward the abstract and delving into the occult. He never acquired the habit of writing notes, always claiming (and proving) that he was able to retain complete detailed data on his researches and experiments in his mind. He said that he intended to live to 150, and upon reaching age 100, would write his memoirs, which would include a detailed record of all the data he had compiled during his researches and experiments. At his death – during World War II – the contents of his safe were impounded by military authorities, and nothing has been heard as to the contents of the records – if any – it might have contained.

One of the peculiar inconsistencies of Tesla's character was revealed when two high honors were offered him, and he rejected the one but accepted the other. In 1912 it was announced that Nikola Tesla and Thomas A. Edison had been chosen to share the Nobel Prize, including the $40,000 honorarium. Tesla could well have used the $20,000 at the time. Nevertheless, he flatly refused to share an honor with Edison. However, when in 1917 the AIEE's Edison Medal – founded by anonymous friends of Edison – was awarded to Tesla, he was persuaded to accept it, after first refusing.

The Esteemed Eccentric

Tesla's natural demeanor was that of the aristocrat. With the passage of time and the depletion of his resources, he sank into a condition of genteel poverty. Continuing to live in the best hotels, his credit would become exhausted and he would be forced to seek other quarters. Finally, moving into the newly opened New Yorker, he found his problems solved. Some of the organizations for which he had made millions arranged with the hotel management to take care of the aging genius.

Having once met Tesla through the mutual friendship of the intrepid Hugo Gernsback (possibly Tesla's last friend) this writer later recognized the distinguished pioneer strolling in the grand concourse of the Pennsylvania Terminal. Impeccably dressed, his head bowed low over his pristine collar and red-and-black silk necktie, his whole bearing was that of a high-born nobleman from the past.

"Good evening, Dr. Tesla," I ventured, disturbing his solitude in the midst of the turmoil. "Are you catching a train for somewhere?' His soft-spoken reply was memorable. "No,' he explained, "I often come here to think."

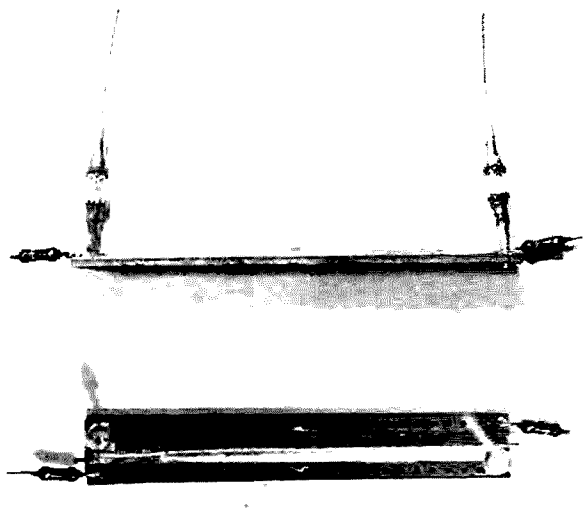
Tesla insisted on carefully wiping each item of silverware, china and glass before starting a meal, using a fresh napkin for each. In view of this effort to achieve perfect sanitation, it seems inconsistent that the maids reported Tesla's room to be an "unholy mess." It wasn't Tesla's untidiness they complained about – it was the pigeons! When he was not feeding them out in the park, he fed them in his room, where he left the window open so they could come and go.

The gold-plated telephone beside his bed, over which he enjoyed a universal frank to talk to anyone anywhere in the world without charge, was the roost of his favorite pigeon, a white one with grey-tipped wings. "When she dies, I will die," predicted Tesla.

And so it was that one day in January 1943, his favorite dove paid him her last visit. "She was dying," lamented the lonely, unhappy Tesla. "I got her message, through the brilliant beam of light from her eyes."

One of the maids, observing that the "Don't Disturb" sign had been hanging on Tesla's doorknob for an unusually long time, used her pass key to investigate. Tesla had passed to his reward, leaving his gaunt 87-year-old frame peacefully in bed. She fed the mourning pigeons, gently ushered them out, and closed the window.

. . .Quinby



Author's Note: I am indebted to the late Hugo Gernsback, friend and confidant of Nikola Tesla; to *Prodigal Genius*, the biography of Tesla by John J. O'Neill; to the *Proceedings of the AIEE*, and various publications for help and information.

A SIMPLE VHF SWR METER

I recently wanted to do some work on a 2 meter antenna and since no other instrument was handy, started to use an SWR meter manufactured for use on the high frequency bands. After some erratic results, it was decided to check the SWR meter accuracy on 2 meters with some carbon resistors to simulate different SWR's. The results readily confirmed that the SWR meter was useless at VHF unless one didn't care whether a SWR was really 1:2 or 1:5. Rather than purchase another SWR meter, it was decided to construct one that would render reasonable results, within 10% accuracy or so, on the VHF bands, particularly 144 and 220 MHz.

There is nothing basically new in the circuitry of the SWR meter to be described. What is different about it is that it utilizes a particularly simple and inexpensive method of construction that yields reasonable results. It can be constructed as a completely self-contained SWR meter or only the pickup element can be constructed and used with an external meter. The circuitry as shown here for the meter utilizes two meter

The heart of the SWR meter is a carefully constructed pickup element. Details of construction are discussed in the text but the photo shows how closely the diodes and terminating resistors must be soldered to the pickup element.

movements so one can read forward and reflected power simultaneously and avoid the annoyance of having a forward-reflected switch arrangement for a single meter.

Pickup Element

The "heart" of any SWR meter of the reflectometer type is the pickup element. Many elaborate forms for such elements have been devised which involve complicated mechanical construction. Such complicated construction does become necessary if very accurate results are desired and if the meter is to maintain linearity over a very wide frequency range. However, over a smaller frequency range and with some minor sacrifice in accuracy, the construction of a pickup element can be greatly simplified. Basically, the pickup element should not cause any discontinuity in the transmission line section in which it is inserted but yet be long enough so enough voltage can be picked up in both the forward and reflected directions to make the meter usable with even low power transmitters.

The pickup element I devised is shown in the photo. It is a 2-7/8" long piece of alternate grid pre-punched perf-board stock. The board is about 7/16" wide and within this width contained 4 separate copper strips spaced about 1/16" or less apart. The center two strips are soldered together to act as the inner conductor continuation of a coaxial line section. To solder the two inner strips together tack solder a bare piece of hookup wire between the two strips and then cover the entire two strips with solder.

Without the use of pickup wire, it will be nearly impossible to develop a smooth solder

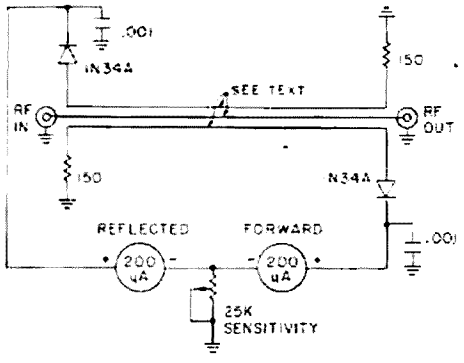

Fig. 1. SWR meter circuit. Two identical meters should be used (current range and internal resistance).

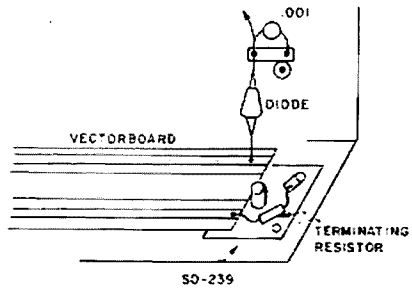

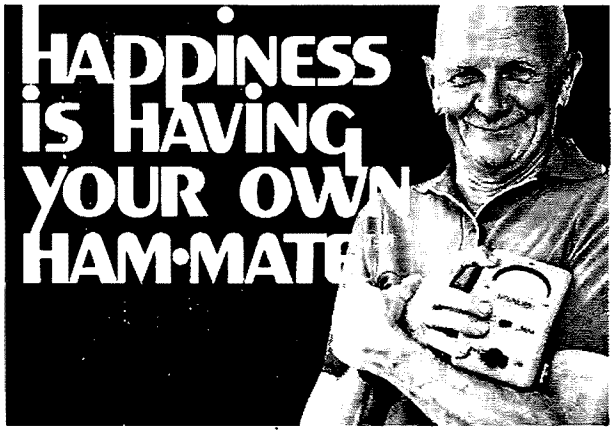

Fig. 2. Center strip of vector board is soldered to center post of SO-239. Other components are mounted at each end of board as shown (only one end shown here).

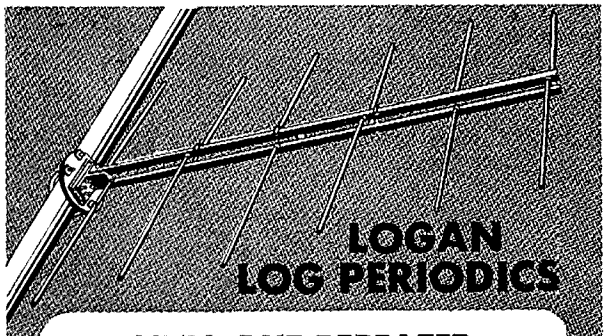
flow between the strip. Each outer strip acts as a pickup element for the SWR meter circuit shown in Fig. 1. The terminating resistor and diode are soldered to each end of the outer strip as shown in the photo and with minimum excess lead length to the strip. The use of a heat sink on the diode is necessary to prevent damage during soldering.

Mounting The Pickup Element

The pickup element made from the board stock is mounted between two approximately spaced SO-239 chassis connectors. The center strip of the board is soldered at each end to the center post of the SO-239 connector. The terminating resistor at each end is grounded as directly as possible to a ground lug held in place by one screw of the SO-239 mounting hardware. These details are shown in Fig. 2. It is important that the terminating resistor be grounded in this manner with minimum lead length. The enclosure in which the pickup element is contained should just be wide enough to accommodate the SO 239 connectors so that when the enclosure is secured together, the pickup element is boxed in by a metal surface on each side except directly above it. Many chassis or enclosure types are suitable for this purpose and the overall size of the enclosure will depend, of course, on the meter used and sensitivity control placement. These details are not covered here because they can be made as desired. They will not affect the basic accuracy of the meter as long as the pickup element is properly mounted and enclosed. The bypassing of the pickup rectifier diodes must also be done with as short leads as possible on



The New HAM-MATE™ Directional RF Wattmeter is a direct descendant of the famous model 43 THRULINE® – the professional standard of the industry. Designed specifically for the serious radio amateur, three models currently available measure forward and reflected power in the following ranges:

4350: 2000/200W, 1.8-30MHz (160 meters to 10 meters)
4351: 1000/200W, 1.8-30MHz (160 meters to 10 meters)
4352: 400/40W, 50-150MHz (6 meters, 2 meters)

All have an Insertion VSWR below 1.1 in 50-52 ohm lines, a minimum of 20dB Directivity, 8% Accuracy, SO-239 female UHF connectors and carry the 12 months guarantee of all Bird instruments.

ONLY $79 (plus $1 shipping)

the bypass capacitor. As shown in Fig. 2, a two lug terminal strip (one lug grounded), mounted on the side wall of the enclosure immediately at the cathode end of the diode will perform this task very well. The length of the IN34A diodes is such that the bypass capacitor cannot be connected to the same ground lug used for the terminating resistor. The leads on the capacitor would be too long and it will be ineffective.

Operation and Results

The dual meter circuit of Fig. 1 reads forward and reflected power simultaneously. The sensitivity potentiometer is set to read full scale on the forward meter and the SWR read directly from the reflected meter. The latter meter can be calibrated for various SWR's by the use of small carbon resistors (100Ω to simulate a 1:2 SWR in a 50Ω line, etc.). Usually, it is only necessary to calibrate the reflected meter for SWR's of 1.5, 2 and 3 at the frequency of interest. Calibrated in this manner, the accuracy of measurement will be roughly 10% and is certainly good enough for most general antenna work. A particularly nice meter display can be made if one can find a two meter movement in one enclosure. I purchased a surplus stereo VU meter which had dual 200 μA movements and used it in the SWR meter.

The sensitivity of the SWR meter is such that transceivers of the 1-2 watt output class can easily be used with it on the VHF bands. The basic meter, of course, can also be used on the lower frequency bands as well and it will retain good accuracy. The only problem on the lower frequency bands is that the pickup strips are so short that more transmitter power has to be used to activate the meter than is usually convenient to use during antenna experiments. No exact tests were made but probably 70-100 watts would be needed to use the meter on as low a band as 80 meters. The meter was used and checked, however, on 40 meters. The accuracy of the meter remained very good and full scale deflection of the forward level meter required a power level of 60 watts. Being an in-line type meter, it can be left permanently in line when used on any band with a minimum of loss.

BETTER CONTROL FOR TRANSISTOR REGENERATIVE RECEIVERS

From time to time, various amateur magazines have had notes on using transistors in regenerative detector circuits. Some time ago, I made a two-transistor receiver, and immediately ran into trouble with the regeneration. The problem was that as the regeneration control was advanced to the point of oscillation, the received frequency was "pulled," and stations disappeared as I tried to tune them in. Also, the start of oscillation was very violent, and when the control was backed off, the dropout was equally sudden and uncontrollable. Some couple of years ago, in 73*, there were a few brief notes on using transistors in regenerative circuits. It was suggested that large values of tuning capacitance and small coils would tame the regeneration, and when this was tried, a big improvement was noticed. The result was that a quite usable unit was made for 3.5 MHz, to operate as a companion to a 1W portable transmitter.

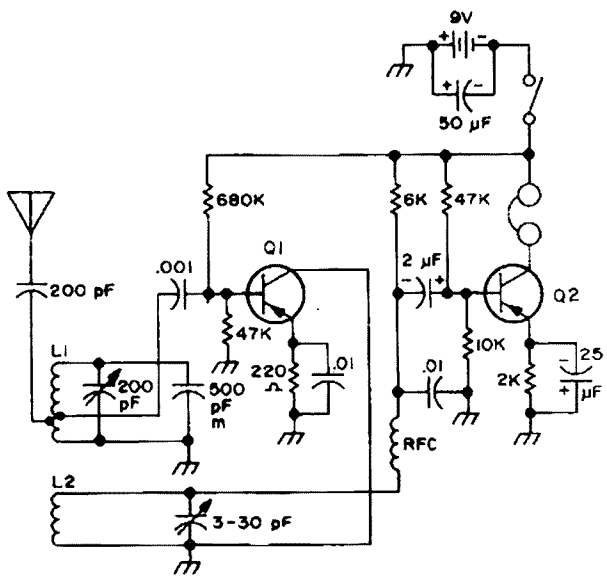

Fig. 1. Revised circuit. Q1 = 2N370, 2N371, 2N372 or 3N2083. Q2 = OC70 or OC71.

Recently, it was decided that the portable rig would be more useful on 7 MHz. The transmitter, (dreadfully old fashioned as it uses a 1T4 and a 3A4) was easily modified, but all attempts to make the two-transistor receiver operate effectively on 7 MHz proved futile. The regeneration just wasn't controllable. The regeneration control was a variable resistor, which not only controlled feedback, but varied the collector voltage. It was reasoned that the frequency shift was due to junction capacitance changes with varying voltage, and this effect would naturally be worse at the higher frequencies.

I then remembered that when I made my first one-tube receiver, in 1946, the regeneration control was not a potentiometer, but a variable capacitor, and the tube's plate voltage was fixed. Maybe the old ways are best; maybe not – but I thought it was worth a try. A simple change in the circuit to that shown in Fig. 1 brought instant improvement. The transistor can now be slid gently in and out of regeneration, and there is only a few hertz shift in the received frequency when this occurs. The receiver is now quite usable on 7 MHz, and I am looking forward to regular QRP contacts during afternoon outings. I throw my antenna wire into a tree, ground the rig to a 40 ft wire, and let it go – all 1.3W of it. The two-transistor regenerative receiver is giving a good account of itself on CW and would make an ideal "last resort" receiver, or as in my case, a real QRP portable unit.

"WHAT'S AN ANTENNA MEASURING CONTEST?"

You'll see," my husband of one year directed. His answers to my further inquiries had me envisioning a large crowd similar to that at a Fourth-of-July fireworks display, with picnickers gathered around plentiful tables and short-order food easily available. On some sprawling platform would be an impressive array of electronic hardware, with a master of ceremonies comparing antennas and from behind a microphone announcing auctioneer style the relative merits of each.

Disillusionment was inevitable when the apparently deserted park finally revealed a small group of people huddled around a few wires. One portable shanty sold candy bars and potato chips. Club funds had been used to supply a tub of ice filled with cans of soda. No other food was available. Gradually some thirty people filtered in, about half of whom brought strange-looking contraptions made of wire, screen, wood and sheet metal, almost none of which I had been used to seeing as antennas.

We walked around looking in on people here and there, and having brief conversations with passing strangers wearing call-letter badges. Everybody seemed to be busy doing nothing, but for some reason my husband radiated excitement and anticipation. I decided there must be something more to come. "They're starting!" Dick said, and abandoned me to rush, camera in hand, to the original group with the wires. I hurried to the spot, fearful of losing a good position for observation. But no one gathered around. There were no official announcements. I asked Dick if anything had gone wrong. Someone was holding up a square megaphone with a wire attached to it, but saying nothing. "No," Dick answered, "It s okay." I stepped in closer to get a better look. "You're in the way," Dick said. I stepped back and almost slammed into a mass of uniformly-spaced spikes being held waist-high.

Dick K2RIW stands in front of his 12-ft. dish which won in both categories, as Dick W2IMU makes a reference measurement with a standard gain horn.

"When will they start?" I asked ingenuously.

"They already have. That's the third antenna."

When it dawned on me that what I was seeing was all there was, I resolved to discover the point of interest by attempting to understand what was happening. I in-

quired about the measuring process, reprocessing the answers to conform to my limited understanding.

Several years and a legitimately-earned license later, I have come to better understand the enjoyment of an antenna measuring contest. But the East Coast VHF Society has grown in those years, too, and the August 1971 annual ECVHFS Antenna Measuring Contest was vastly different from that first one I attended. Picnickers were already hovering comfortably around tables when we arrived at Saddle Brook Park, New Jersey, and quite a crowd was wandering in the pavilion, where a noise-figure measuring contest, a tube guessing contest, and a QSL card competition would soon be getting underway. A tightly-massed gathering identified the registration table where tickets could be obtained for the drawing to be held later. A picnic table with a receiver and calibration equipment had already been set in the field, and 125 ft further out the signal generator waited.

Friendly waves greeted us as we pulled into the main area, and almost before the car came to a stop we were surrounded by inquisitive amateurs eager to watch us assemble Dick's portable 12 ft-parabolic dish and to examine the "goodies" Dick habitually brings along. I set up the baby's playpen and turned away from him and the friendly XYLs to lend my husband the usually much-needed hand, but discovered he already had all the help he needed. I got out

Paul, president of the ECVHFS, holds up the 1296 MHz standard gain horn, as a former president, Al K2UYH, looks on benignly.

QMs with quads collinears, dishes and yagis wait patiently as calibrations are made before their antennas are measured.

the camera and began snapping familiar faces, interesting-looking antennas, and contest activities. When the dish was fully assembled and the competition was about to begin, I interrupted Dick in his technical discussion with several other amateurs to force him to eat a sandwich. A respected amateur requested a picture. Then came the rain, a circumstance luckily avoided at all earlier ECVHFS contests in my experience. Everyone gathered in cars and in the pavilion. Our baby napped in his car bed. As the skies gradually cleared, a young couple accidentally wandering into our area approached the amateurs in the truck near our car, and pointing to a large parabola asked what it was. The straightforward answers were so badly misconstrued and the simple functions of the antennas held in such naively exaggerated awe that I, overhearing, couldn't help but chuckle, remembering my first exposure.

The measuring resumed and the crowd, fortified by amateurs returning from the nearby ECVHFS ham radio auction and flea market, filtered back into the field, some 130 strong. Somebody tapped me on the shoulder. "Do you believe in God?" It was a two-man team taking a religious "survey." I gave them answers to their brief oral questionnaire, dismissing them courteously. Somebody was cooking hamburgers on an hibachi. Two amateurs worked together to repair an antenna with a Bernz-O-Matic torch. Amateurs inquired about the gains of each other's antennas and generally gos-

sipped. DB's written on contest forms were compared for the 26 antennas entered in two categories. A ham received congratulations for having won the noise figure measuring contest. A child played with a stuffed animal won by a parent in the drawing. Someone handed out cucumbers from his Pennsylvania garden. Certificates were issued and plaques given to the 432 and 1296 MHz antenna measurement winners. An ARRL official capitalized on the occasion to present an award of achievement to an amateur. Just as the crescendo of activity began the descent, it began to rain again. Amateurs, YL's, XYL's, supplies, antennas and children were packed into cars and the homeward treck was begun.

These technical diehards won't let a little rain ruin their chance for an eyeball QSO. Left to right are Bill W2DWJ, Dick K2RIW, Reed W2CQH and Al K2UYH.

We began dismantling the dish in the downpour. "What about lightning?" I insisted.

"Don't worry about it."

What's an antenna measuring contest? It's a serious electronic effort: a place to announce an antenna of your own design or to measure the gain of a favorite commercial one. It's a chance to exchange ideas or equipment; it's a family picnic, a brag-and-gossip session, a place to display your specialized electronic acumen, an opportunity to meet friends as well as the serious VHF amateurs; it's an experience. But you've got to see one for yourself.

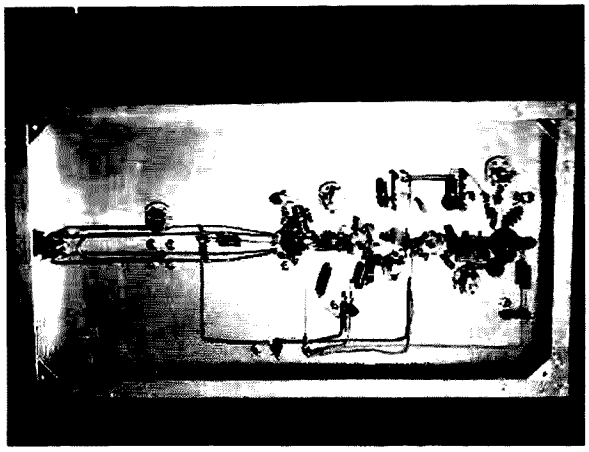
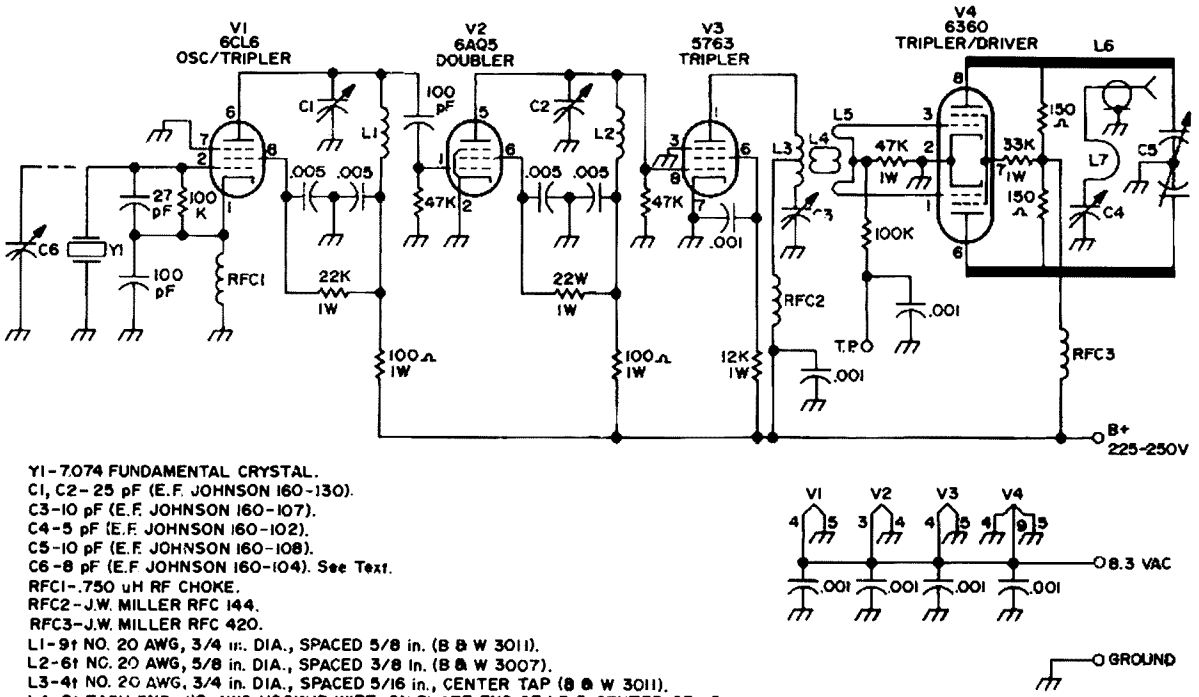
SSB ON 432 MHZ

Recently, after a fruitless evening of calling CQ on 432, I decided it was time more hams were encouraged to use this interesting band. Most people think that 50 miles on 432 is real DX. That's just not true. Although my best DX this past year was only 415 miles, many hams cover distances as great as 700 miles: some claim more. SSB is now starting to come into greater use, and does show its worth on 432, so I decided to put together a complete working unit. This unit is a modified version of a design by K7RKH that originally appeared, in part, in the old VHF'er magazine.



When building this mixer I decided that, while the General Class operators would probably be more inclined toward construction, there are also many Technicians with 50 MHz SSB who would like to get on 432. With this idea in the back of my head, I chose 50 MHz as the mixer input frequency.

While some 432 MHz mixer designs have appeared in print, it appears that few hams have completed rigs that work with much success. One reason for this may be they have not been able to obtain the degree of oscillator stability required. Some have gone to the extreme of building a transistorized oscillator inside a thermos bottle, burying it in the ground and letting it run 24 hours per day. This of course results in excellent stability. With a little care my oscillator chain will equal or surpass the current 432 rigs. Keep in mind that only one hertz change in the oscillator will give you a change of 54 hertz in the output.



At VHF/UHF the use of choice selected hardware such as ceramic tube sockets, good quality resistors and capacitors and constant-impedance connectors is a must. Those inexperienced in working with 432 circuits should use a copper chassis, but advanced experimenters can construct this oscillator/mixer on other materials such as aluminum, using the necessary precautions such as short leads, direct ground paths, and

The 382 Mc oscillator chain is on the left, the 432 Mc mixer with an added buffer amplifier in the center. and a 500 watt cavity on the right.

Fig. 1. Circuit diagram of the 382 MHz oscillator chain.

proper bypassing/decoupling. Shielding per se is not a critical factor here as power generation itself was not the desired end product.

Construction

The oscillator chain is constructed on an aluminum chassis 2x7x13 in. Be sure to make preliminary parts layout, as the full length of the chassis will be used. If you are not experienced at building VHF circuits it is recommended that you build only one stage at a time and get it working before proceeding to the next. The mixer was built on a separate 2x5x7 in. chassis for experimental purposes, but you may want to build both on a larger common chassis.

You need not include frequency adjust/variable capacitor C6, but if you do it will give you about 100 kHz change at the output frequency, more than enough to correct for crystal error, or to enable you to move to a predetermined frequency. With proper adjustment of C6, you could actually go to full transceive, but in actual practice a fixed crystal frequency would be better in case you are running skeds.

Tuneup

A grid tip meter is an absolute must. Without one you will not have much success in tuning up because the tuned circuits will actually pick either the second or third harmonic of the previous stage. Dip each stage as follows: C1/L1 dip to 21.222 MHz, C2/L2 dip to 42.444 MHz, C3/L3 dip to 127.333 MHz. There is only one dip in C5/L6, so it is a simple matter to peak for maximum rf output. To assist in tuneup, construct an rf indicator from a GE49 pilot bulb and a 1 in. loop of hookup wire. After each L/C circuit is dipped, apply filament and B+ voltage. Starting with the oscillator, hold the indicator near the plate end of each coil and peak for maximum output. Now go

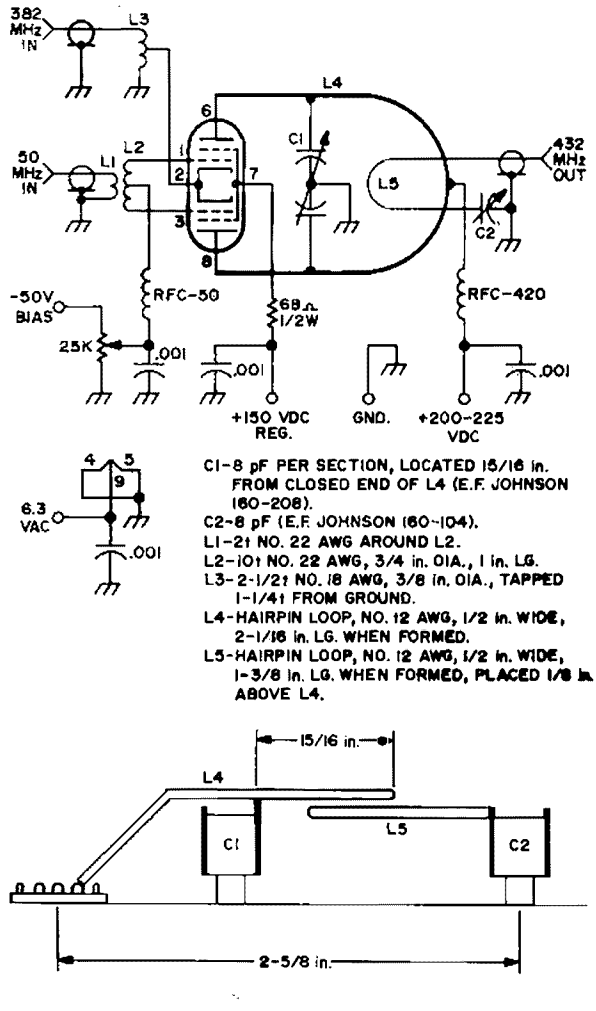

Fig. 3. Circuit diagram of the 432 MHz mixer, and the pictorial of the tank circuit.

back and redip each coil to make sure you are still on the proper frequency. When each stage is in tune there will be enough output to brightly light your indicator. While tuning C3/L3 for maximum output, couple your indicator to coil L5 and peak C3. Now connect a vom or vtvm to point "TP" and set your meter to read 100V dc. Again apply power and tune each capacitor for a peak reading on your meter. The final reading should be 50–85V dc. When tuneup is completed you should have 3–4W of 382 MHz rf, much more than will be needed, but the excess will help to overcome circuit losses.

Mixer

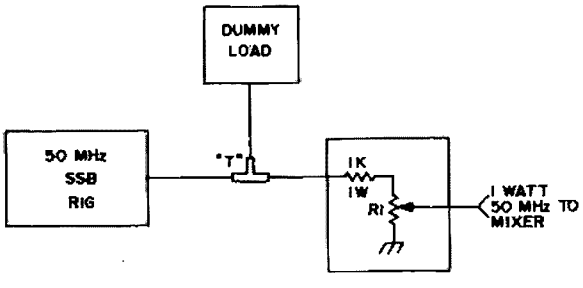
A 6360 works as a mixer with suitable modifications, but it requires more drive and injection. A 6939 costs more, but has more output with less drive and injection, less than half that of the 6360. The 382 MHz

injection is fed into the cathode through a tapped rf choke resonant between 382 and 432 MHz. Care must be exercised not to resonate this coil at 432 MHz, for if you do, output instability will result. The tap, placement of which is critical, provides an impedance match and expends the rf driving power efficiently for proper loading of the cathode. The vr tube for the 6939 screens is an OA2. The bias is set for 35 mA standing plate current with no drive.

The simplest method of obtaining the 1W of 50 MHz SSB, without making modifications to the rig, is to feed the full output of the driver into a dummy load with a tee connector and pull off only the amount of rf needed (Fig. 4).

Final Tuneup

Connect the 382 MHz oscillator chain to the mixer with a piece of RG-58/U coax about 14 in. long. This length can be critical, so if any problems are found, vary this length a bit. Connect the output of the mixer to a proper dummy load or wattmeter. Apply the appropriate voltages to the oscillator/mixer and adjust the 6939 static plate current to 35 mA. Now repeak the oscillator stages for the maximum voltage at "TP." Apply a small amount of 50 MHz drive and dip the mixer capacitors C1 and C2 for maximum output. Again repeak all capacitors and adjust the 50 MHz drive to the 6939 for about 50 mA plate current. With 225V on the oscillator plates, total current should be about 165 mA. Do not try to run the oscillator chain at its maximum input as the increased output if not needed and a lower input level will give you a much more stable unit. Allow at least 15 minutes warm-up before making the final frequency adjustments.



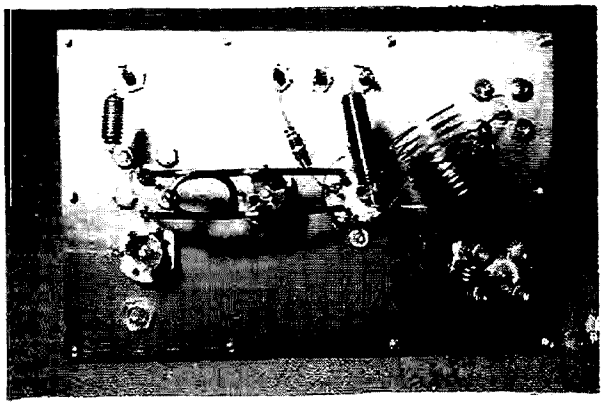


Fig. 4. Method of obtaining low level drive to the mixer. R1 is a 1K A.B. composition pot. This may be built in a small minibox using rf connectors.

Bottom view of the 6939 mixer, with L5-C2 at the left and L3 at the lower right.

Summation

If problems such as FM'ing should be encountered, decrease the 50 MHz drive, since we're more interested in quality than in power. You should now have enough output to drive such tubes as the 6939, 5894, 2C39, and, amazingly enough, should be able to drive a 4X250 to as much as 135W input, class AB1.

It is always recommended that a filter be used on the output of any mixer worked directly on the air. When driving low Q buffer or amplifier stages, some of the spurious energy such as 382 MHz will get through to the output. Some odd loading effects will occur in broad frequency amplifier stages because the 382 and 432 MHz energies are relatively close together for a UHF circuit. A strip line filter between the mixer and the final amplifier stage is highly recommended. Refer to the ARRL VHF Handbook. Even an output filter is desirable. Although I have only used CW and SSB the 50 MHz drive may be almost any mode – CW, A3, SSB, FM, FSK, PM, or what have you – but the modulation/purity index must be clean or it will show up in the output.

If this mixer is used as a source signal directly for tuning up 432 antennas, the swr bridge will go crazy and will not give readings truly indicative of tuning or antenna performance.

I am using a Heath SB–110 as the 50 MHz driver, using the auxiliary transmit with a 5.031 crystal (about 432.030) in the auxiliary oscillator and have had good on-the-air comments. See you soon on 432 SSB.

A 185 AMPERE AC ARC WELDER

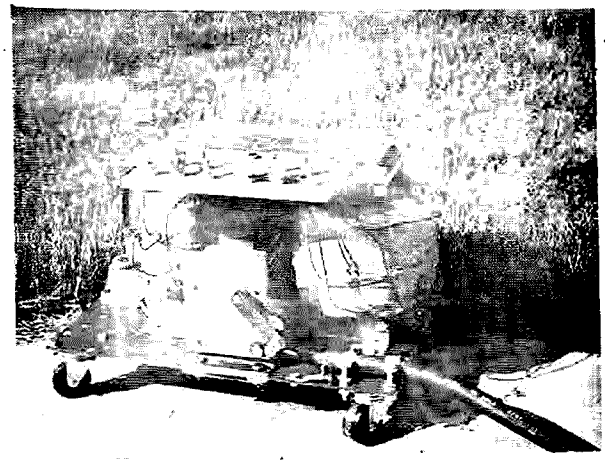
The welder, although not an essential item in the hamshack, is a welcome addition to the experimenter's supply of tools. It serves such areas as tower construction and general repair. The high cost of an adequate commercial welder and my native curiosity started me on this project which has seen a year and several different transformer designs pass. The present unit is the culmination of my experimentation. It is a continuously variable unit that will weld to 185 ac amperes maximum. The duty cycle for this unit at maximum current is about 15%, which would not satisfy the industrial user, but for the average shop is quite adequate. A simple duct and fan cooling arrangement could raise this value.

The type of transformer I have designed allows one to control the leakage of the unit, which in turn controls the maximum amount of current that can be drawn. By varying the amount of leakage, one can control the current available at the welding electrodes. Most transformers are designed to minimize leakage. This application is an exception. The formula used to calculate the number of turns for the primary and secondary windings is:

$$V/N = 4.44\ B\ F\ S\ A \times 10^{-8}$$

B = flux density in gauss (flux is the number of lines of magnetic force and is dictated to a certain degree by the metal used in the core).

F = frequency of operation of the transformer (in this case 60 cycles).



S = stacking factor (this allows for varnish between the laminations of the iron core).

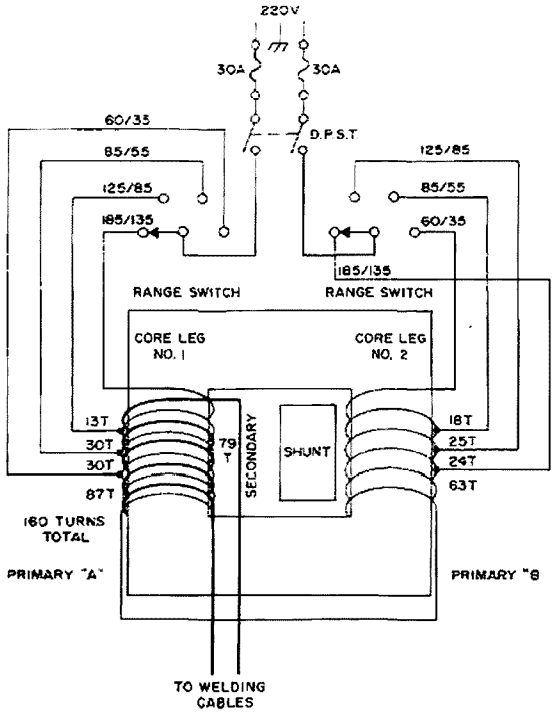
A = cross-sectional area of a core leg in square centimeters.

V = volts applied or desired.

N = number of turns required.

After choosing the flux density at which to operate the transformer, considering the iron used (I chose 15,000 gauss), the other terms are fixed by external conditions, except for the number of turns and the cross-sectional area. I picked a cross-sectional area that would be large enough to

The completed welder. Note the on-off switch, fuses and shunt mechanism in place.



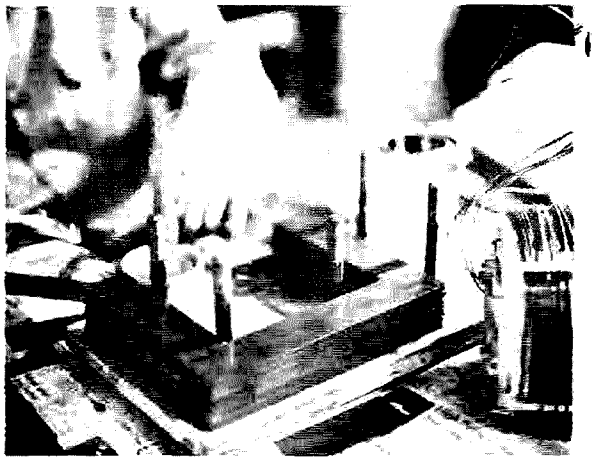


Fig. 1. Welder schematic.

give a reasonable value for the number of turns required. The cross-sectional area that was chosen required approximately 235 turns on the primary (the winding connected to the 220V main line) and 79 turns on the secondary (the winding the welding cables are connected to).

To vary the leakage of welding current, there are two controls. The range switch, which is the coarse current control, actually varies the proximity of the primary winding to the secondary winding by a series of taps which puts a greater or lesser part of the primary directly over the secondary and the rest around the other leg of the core. The farther apart the primary and secondary, the greater the leakage and the lower the welding current. Vernier current control is accomplished by sliding a laminated iron bar between the two coils and thus shunting flux away from the coil on the other leg of the transformer (leg 2), see Fig. 1. Flux is the term used to describe the magnetic field which couples the primary to the secondary and thus allows the transformer to function. The less flux, the less coupling and the lower the welding current.

Here, the U-shaped part of the core is being assembled. The large bolts and plywood base are part of the temporary clamping device for the core.

Construction

The core itself is a laminated structure made of .025 in. thick .25% silicon steel sheet. Plain cold rolled steel will serve if the silicon steel cannot be located. The steel is cut into strips as per Fig. 2. The laminations are then assembled with varnish in alternating layers 1 and 2 (Fig. 2). A metal shear is necessary to cut the laminations. Make sure that the shear is in good condition or you may have to file burrs off each and every lamination since it is necessary to avoid metal-to-metal contact between the laminations. If liberal amounts of varnish are used and the laminations are reasonably free of

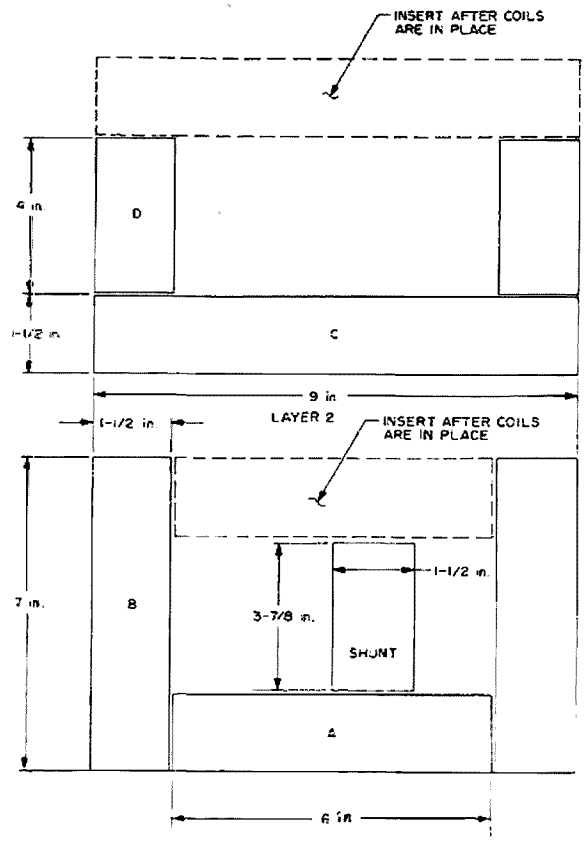

Fig. 2.

burrs, no problems should be encountered.

After the U-shaped part of the core is completed, it should be placed between two ¾ in. plywood boards and clamped tight to remove excess varnish. After clamping, the core should be approximately 2¾ in. high. This will require approximately 109 layers of iron. The core laminations may need to be aligned after clamping the first time. Although the varnish will not completely dry for over 9 months, it is very difficult to realign the core after only a few hours, so make sure that it is square. The shunt can also be assembled at this time. The partially finished core and remaining lamination can now be put aside to cure and the coils can be wound. After a week, the clamps can be removed if the core is handled with a little care.

The first job is to build the bobbins that the coils will be wound on. They are constructed out of 3/32 in. plywood, which can be purchased at any hobby shop dealing in radio controlled airplanes. I have left out the exact dimensions for the bobbins because they should be custom fitted to your core legs. The bobbins were assembled with gauze and glue (Fig. 3).

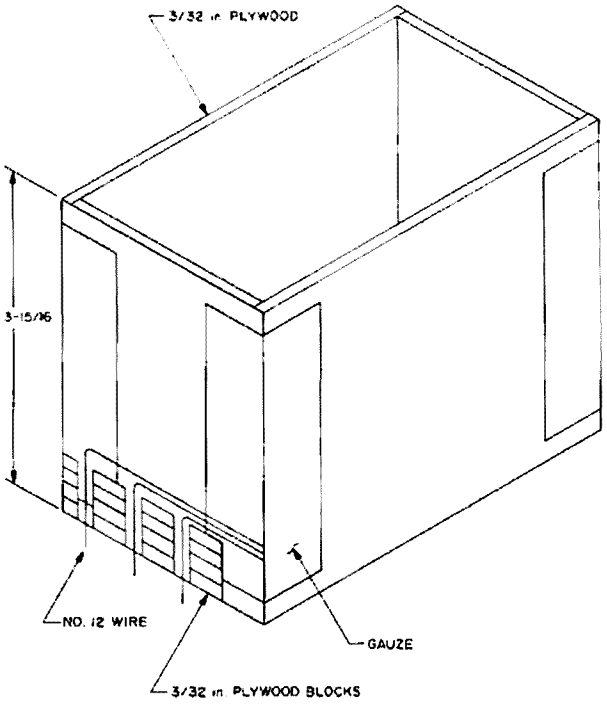

Fig. 3. Bobbin. Note: *Adjust the inside dimensions of the bobbins to fit the core that you have constructed. The bobbin shown is the one for the secondary in which three 12-gage wires are wound together. For the primary, only one wire slot is required.*

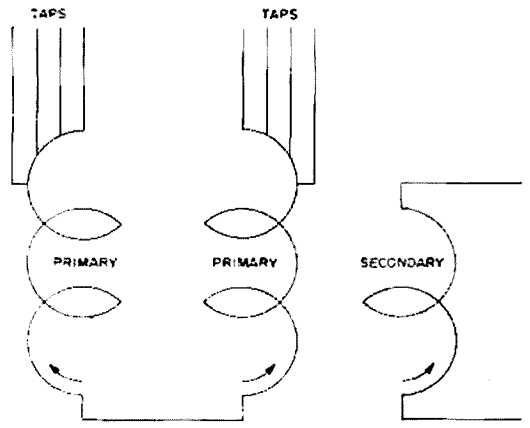

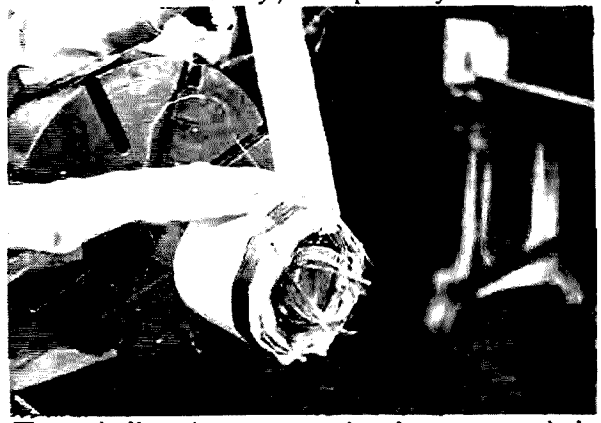

Fig. 4. Coil orientation pictorial. Note the direction of the windings of the various coils and follow it exactly!

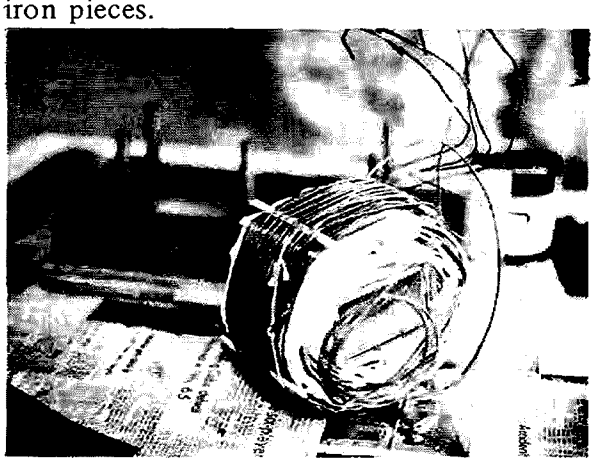
About 700 ft of 12-gage copper magnet wire is required to make the coils. It was obtained through a local wire distributor. The secondary was wound first. It is a trifilar winding consisting of three strands of 12-gage wire side by side and wound together.

Cut a piece of wood that will just fit inside the bobbin and clamp it in a vise; then get a friend to help and start winding. Seventy-nine turns are required on the secondary (Fig. 4). This will be approximately 6 layers of wire. Between each layer place a couple of layers of paper insulation (wrapping paper is fine) and four ¼ x 4 x 3/32 in. plywood spacers on each of the four sides. Varnish the paper after it is wrapped around the coil. The air spaces provided by the plywood spacers allow for air cooling of the coils during operation. The primary coils are wound similarly, except they are mono-



The winding is most easily done on a lathe although it can be done by hand. Note the tap wire protruding from the coil. Here, paper insulation is being placed between two layers of wire.

filar windings consisting of one strand of wire. One hundred and sixty turns are wound directly over the secondary. One hundred and thirty turns of primary are wound on the second bobbin. A layer of gauze is placed over the last layer on each bobbin and varnished.

In wiring the two primaries together, the relationship of the two coils in respect to the direction they are wound and the way they are connected together is critical, so follow the diagram to the letter. If by chance a mistake is made, the welder will hum loudly and heat up excessively when turned on. When winding the primaries, observe the positions of the taps and place them as you wind, using a 100W soldering iron and rosin-core solder. The ends of the coils, both primary and secondary, can be held securely by fastening the ends of the wire with string. Tie the string onto the end of the wire, then wrap the string around the coil several times and tie it.

Remove the U-shaped part of the core from its clamps and clamp the bottom of the core with two 1½ x 1½ x 1/8 x 10 in. angle-iron pieces with holes drilled at the ends to accept 3 in. machine bolts. Insert the bolts and tighten. Place the coils on the legs of the U-shaped piece and complete assembly of the core. Clamp the new assembled portion of the core with plywood and C-clamps. After several days, angle-iron clamps can be placed on the top of the core as on the bottom in place of the C-clamps. The phenolic board for the range switch can be mounted directly on one of these angle-iron pieces.

A complete bobbin ready to be placed on one of the core legs. Note the string used to tie down the end of the primary winding.

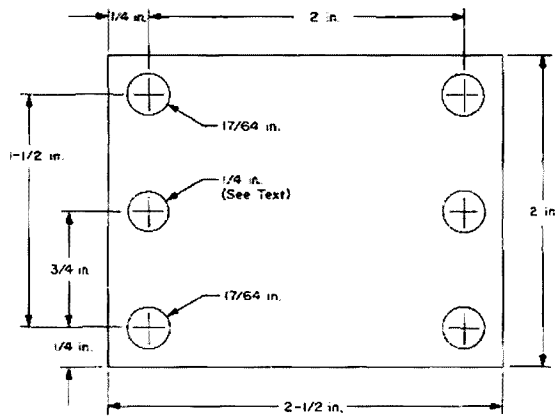


Fig. 5. Shunt clamp plate. Note; *(1) Two plates are required; (2) One of the holes marked for ¼ in. hole in one of the plates is drilled with a #6 drill and tapped with a ¼ x 20 tap. This will ride on the threaded rod which, when turned, moves the shunt in and out of the core.*

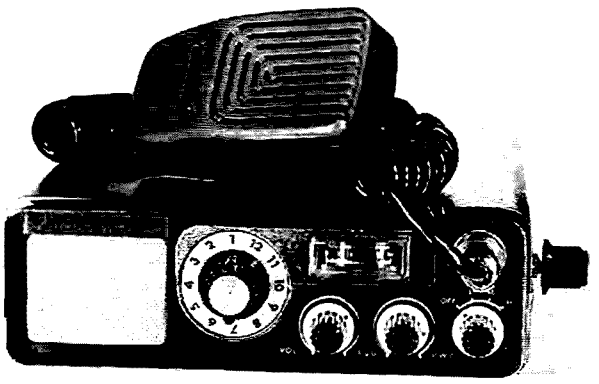
If the shunt has not as yet been made, it can be done at this time. It is made just like the core. It is a stack of 3 7/8 x 1½ in. iron plates varnished together; however, it is only made 2 in. high instead of 2¾ in. as the core proper. Two 3/8 in. plates, one aluminum and one phenolic, are drilled appropriately to clamp the shunt (Fig. 5). One of the guide holes in the aluminum plate is threaded (¼-20). A threaded rod along with a support rod on the opposite side of the shunt both support and move the shunt in and out of the core as the threaded rod is turned. Minimum current for a particular range is when the shunt is all the way inside the core and maximum is when the shunt is all the way out.



For the main switching deck, a piece of 3/8 in. phenolic board is used. Brass bolts are mounted in the board and serve as binding posts. When shorting wires are connected across the appropriate posts, a particular current range is selected.

Observe the wiring diagram. The arrangement of parts is not critical but try to keep the secondary leads as short as possible. The electrode and ground clamps as well as a face shield can be purchased from Sears, Roebuck. The welding cables, two 12 ft lengths of 4-gage stranded wire, can be purchased from any welding supply house.

At this time there are three of these welders in operation and functioning quite satisfactorily.

WIN THE RIG OF THE MONTH!

ROSS&WHITE

The Ross & White two meter FM transceiver seems to have been overlooked by many amateurs because of its low price. Just take a look at some of the features of this rig and see what you think of it on a dollar for dollar basis as compared with the other available rigs.

If you are not yet on FM this is your golden opportunity to win a great FM rig free. Just follow the instructions below and enter the contest – there is nothing to buy – no obligation – it's absolutely free. If you are already on FM, then you can surely use this rig as a second (or a first, since the chances are that it will perform better than the one you are presently using) rig for the car – office – ham shack – trips – etc. You might even want to use it as a shoulder portable – it is ideal for this.

12 CHANNELS

While you may not need this many channels right now in your area (if you live outside of the larger cities, the east coast and midwest), the chances are that you will be needing them very soon, for FM is growing incredibly fast and the number of repeaters has doubled in just the last year.

WARPING CAPACITORS

Many of the lower priced transceivers economize by leaving out the warping capacitors on the receiver oscillator. The result is that you may well have a tough time hearing a repeater – or you will have to pay a premium for extremely accurate crystals to make up for the lack of capacitors. It costs extra to put these capacitors in the Ross & White – but they are there.

FRONT SPEAKER

Have you ever tried to hear a voice coming out of a two inch speaker which was aimed at your feet in the car? By the time you turn up the volume to where you can hear the speaker over the car noise the distortion is so bad that you can't understand what is being said. The speaker on the front panel of the Ross & White overcomes this problem – it is aimed right at your ears and you can hear everything clearly.

TEN WATTS

Most repeaters are designed to work with mobile rigs running ten watts output. This is exactly what you get with the Ross & White and it is certainly adequate. If you hunger for more, the most economical amplifiers are those designed for ten watts drive. The power switch on the front panel of the rig permits you to cut down to one watt or even 1/10th watt. This don't make much difference in the car – after all, what is ten watts to your car's power system? But this rig can be used with a small nicad pack as a shoulder portable and in this case the 1/10th watt position will be fine for most use – with the one watt available if the tenth watt doesn't cut the mustard – and the ten watts can be used for short periods when you are desperate. What other rig can do this?

VERY SMALL

Mounts anywhere – or goes under the arm for walkie-talkie use. One of the smallest 10 watt rigs available.

LOW INTERMOD

One of the big miseries in FM is interference from nearby or overly strong adjacent channel repeaters. The ceramic i-f filter in the Ross & White virtually overcomes this problem. This rig will perk perfectly in areas where other rigs are completely bombed out. If you are a newcomer to FM you may not appreciate the importance of this feature – if you are an old timer you wish you'd bought one of these rigs earlier.

S-METER

So who needs an S-meter? Once you try to get along without one on FM you know quickly who needs one. One way to know when you can or can't get into a repeater is to see how strong you are receiving it and you can only do this with an S-meter. When you hear more than one repeater on a channel you can only tell one from the other by signal strength. And without the meter how can you check various antennas of your own and others? The S-meter is very important.

TONE BURST

The prize Ross & White transceiver will include one of the excellent Ross & White tone burst units. This set normally sells for $280 with this tone burst unit built in and $240 without. The tone burst permits you to turn on repeaters which are matched to this type of entry – lets you operate tone burst functions on repeaters – etc.

MIKE-ETC

A matching mike and mounting bracket are included with the rig.

HOW TO WIN!

Take the entry blank from page 175 (or even a copy of it) to your local distributor and get him to initial it. If you spend anything during the visit have him mark that in – and should you be the winner that will be refunded in its entirety. Then send the entry blank to 73 so it can be in the hat for the next drawing. Extra entry blanks are available at the distributors listed on pages 176-177. No purchase is necessary, of course.

FULL REFUND

When you get your local dealer to initial your entry blank you should have him mark down at the same time the amount that you have spent with him during your visit. If your entry wins you will get a check from 73 Magazine for the amount of your purchases.

WHEN IS THE DRAWING

A drawing for the Rig Of The Month will be held on the 15th of each month. All entry blanks received before that date will be eligible for the prize rig.

The Ross & White transceiver drawing will be held for the following month's drawing. The drawing for the Ross & White will be December 15th – Merry Christmas!

G. W. Goodwin VE2DQ

Deux Montagnes, Quebec
Canada

A SOLID SOLID STATE BREADBOARD

If transistorized projects are your "thing" then this article is for you.

Many times an interesting article appears in your favorite radio magazine or other publication, but some particular transistor or specific component is not readily available.

The junk box, however, yields something similar; or perhaps your friendly supplier can sell you something "just as good," not having exactly what you want in stock.

All too frequently this is the situation where we get into trouble if we make up a printed circuit board and carry on with our substituted components. Upon completion, we invariably find that our pet project leaves something to be desired, if it wasn't a complete waste of time.

Endeavoring to improve matters, we then continue merrily on our way unsoldering and substituting other condensers, resistors and what have you, until our project looks in sad shape indeed. So sad in fact, that we could cheerfully throw the whole thing out into the garbage can before the XYL gets her soft little pinkies on it first and does it for us.

P.C. boards are just not intended for this sort of treatment.

Yours truly has tried for many years to circumvent Murphy's Law which, in general, states that if anything can go wrong, it will. Personally I have found this law to be as inviolable to the constructor as George Simon Ohm's.

After some few failures of this sort – and being of a somewhat stubborn disposition by refusing to give up ham radio – I decided something better had to be done to improve the situation.

What is required primarily is something other than P.C. boards until satisfied that the circuit, with the substituted components, is working as intended.

All components should be easily accessible to facilitate any changes we deem necessary.

Once one is satisfied with the circuits operation and no further substitutions or alterations need to be made, then a P.C. board can be made up and all the bits and pieces transferred and transformed into the thing of beauty it was intended to be. The answer to this, of course, is the so-called "breadboard."

The vision of a breadboard brought to mind the nostalgic days of World War II when we were privileged to see a well-known commercial receiver in the process of development. Each resistor, bypass condenser and all the sundry bits and pieces that go to make up a receiver were individually mounted on a piece of Bakelite (remember that "low loss" stuff?) with a pair of plugs and a pair of jacks for easy changeability.

The whole receiver was spread out, with little room left over, on a bench measuring about 8 x 10 ft in the center of a room for easy access to any component which the design engineers wished to change.

Well, that is a solution, but hardly a practical one for the average ham. So what else is new?

An examination of the problem shows that our circuits require 7 or more basic connections, namely – emitter, base, collector, input, output, a common or ground and a "hot" line from the voltage source. A couple of neutral tie points should be added for convenience. These basic connections are always required so they should be made permanent fixtures.

Copper nails, screws, or what have you hammered into a piece of wood have some use, but again remembering Murphy's Law it will be apparent that the component to be changed is the one soldered under all the others. Not too convenient to say the least. What is required is a larger soldering area.

Also required is a means of holding variable condensers, potentiometers, phone jacks, etc., which is taken care of by the usual panel. The panel, however, should be kept as shallow as possible to facilitate wiring and any changing of components from the front rather than keep juggling the board around every time a change is necessary.

There should also be room on the board for easy mounting of such things as coils, crystals, or transformers as required for any individual project.

With the foregoing points in mind, the following simple but highly effective breadboard was constructed and has proved to be well worth the time and effort spent in construction.

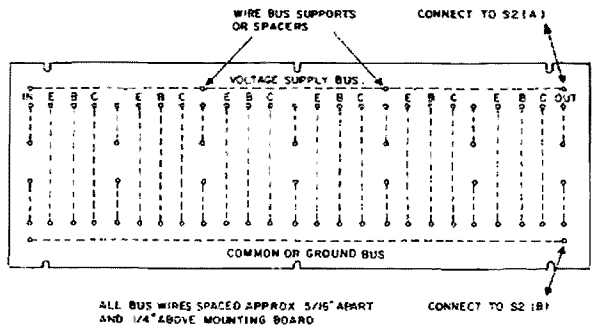

Fig. 1.

Representative dimensions are shown in the accompanying sketches but this, of course, is left to the discretion of the individual and his personal requirements (see Fig. 3).

The board shown has a capacity of six transistors but obviously only one or more need be used at any one time.

A suitable computer board, approximately 8½ x 3 in. stripped of any copper which will interfere with the operation of the assembled board is ideal.

It is not a requirement, however, and any piece of insulating material will do, even wood or masonite.

A series of holes are then drilled according to Fig. 1 to accommodate No. 14, or larger, solid tinned wire bus leads which are bent and fed into the appropriate holes, leaving each wire spaced about ¼ in. from the top of the board and approximately 5/16 in. apart. This spacing keeps the board clear of all resin residue which would build up in subsequent use if the wires were

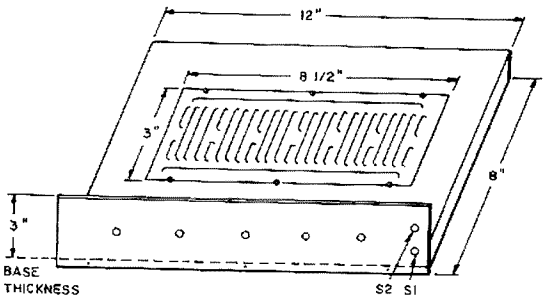

Fig. 3.

placed directly on top of the board. It also facilitates cleaning the bus wires of excess solder buildup when it is only necessary to tilt the board up, resting on its panel and run a hot iron along each wire when it will run off, leaving everything nice and clear again, ready for the next project.

If you use a computer board and have any usable copper underneath each hole where the ends of the bus wires project, you can anchor each wire by soldering and snipping off any excess wire.

If not, an alternate means, and just as satisfactory, is to have about ¼ in. of bus wire project through each hole and then bend it toward the outside edge of the board and flush with the bottom. Each end is then given a slight twist of about 45 degrees to the left for all those wires terminating at one edge of the board and to the right, or opposite direction, for those terminating at the opposite edge. See Fig. 2.

This opposite twisting is necessary to prevent the bus wires from falling against each other when fastened to the base, holding them rigidly in place. Don't worry about it at this point if all the wires are flopping around in the breeze; just make sure they won't touch each other when mounted and fastened down on the base.

Our breadboard is now required for the base and as the name implies, one can actually be used just as baking tins can be used for chassis. However, any suitable piece of lumber on hand can be used either finished or unfinished, painted or unpainted, depending on your aesthetic taste. If you are a stubborn type and insist on using one of the XYL's baking tins, don't forget to insulate the bus bar board from it first before fastening the two together.

The actual size of the base is not important, but it is recommended that it be 2 or 3 in. larger around each edge of the bus board and something about 12 x 8 in. would do fine.

The bus board is then centered onto the base with all the bus wires in place and fastened down with six wood screws (Fig. 3.)

A shallow panel is now required which can be aluminum, thin plywood or what have you, drilled with a series of 3/8 in. mounting holes for variable condensers, pots, etc., which may be required to be used later when trying out some circuit. A small speaker or meter should also be considered at this point. This is left to the discretion of one's individual requirements. The panel runs the length of the base and is fastened to the edge of the base with a couple of wood screws.

Two toggle switches are an integral part of the board. They are mounted permanently on the right hand side of the panel and wired as shown in Fig. 4. S1, a DPST, controls the on-off function, and S2, a DPDT, switches or reverses the power supply, be it battery or variable voltage power supply, depending upon whether a PNP or NPN transistor is being used.

A battery snap connects to the on-off switch, S1, for convenience in swtching to different battery holders and voltages as required, for those not in possession of variable voltage power supplies and who must use batteries. If batteries are used, a suitable clamp should be incorporated to hold the battery down. This is easily fashioned from a piece of scrap aluminum,

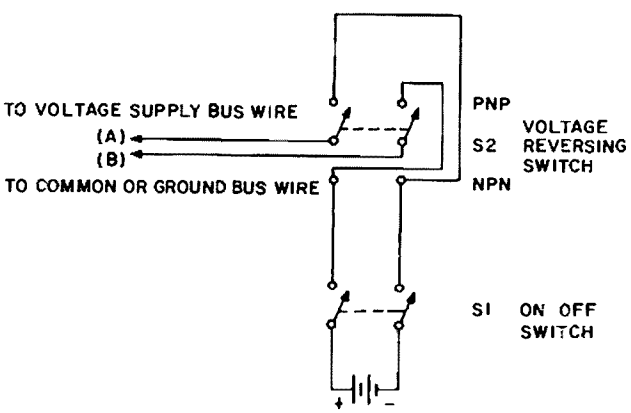

Fig. 4.

wire, or even an elastic band and should be mounted on the wood base or panel, adjacent to the on-off switch, S1.

For those with variable voltage power supplies S1 is probably not required and can be connected to the voltage reversing switch, S2, directly through a plug and jack arrangement. It could even be made an integral part of the board if desired.

In using the board any components such as coils, transformers, etc., not provided for on the panel are conveniently placed on the base adjacent to the bus wires to which they connect. In most cases it will not be necessary to fasten them down, but this can be done with wood screws if required.

As for the transistors, they can either be placed in sockets and wired to the appropriate bus wires or soldered directly onto each bus wire if the leads are long enough, whichever one prefers.

Fixed resistors and condensers are simply soldered onto each bus wire as required without fitting or cutting off excess lead lengths, and no attempt is made to have the circuit look pretty at this point. If we wanted it to look pretty, we could tie a pink ribbon in it or something – whatever your favorite color.

If a number of connections terminate at any one bus wire, spread them out rather than have them sit one on top of the other under one blob of solder. If it is then necessary to unsolder a component or lead, the other half dozen or so won't come off too.

By now some purists are screaming like mad about efficiency and losses and making rude remarks. Don't you believe it, or if you do, forget it temporarily, as we are only interested in getting a circuit to percolate properly at this point in the overall scheme of things. The efficiency can be found with this circuit board first and then built into our finished project – or can it?

Upon reflection, Murphy's Law also states that while the breadboard model functions perfectly, the finished product won't. Oh well, at least you will have tried before getting out of the game altogether.

DID YOU EVER WANT YOUR OWN COMPUTER ?

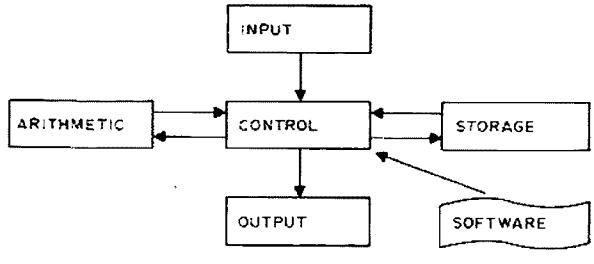
The objective of this article is to provide a ham with enough information to allow him to build a pretty nice minicomputer. An alternative to building your own is at least understanding what makes the brain machine tick. This means if you don't meet the qualifications of a computer builder, you can buy yourself a good used computer and understand enough of its operation to put it to work for you. (Hint, do not trade the XYL in on a used computer – the computer would undoubtedly make a more intelligent companion, but it would have a heck of a time washing your socks.)

The basic requirements for being a computer-builder are; of course, patience, clean living, a large state-of-the-art goodie box, and/or lots of money. You must also have an understanding wife and kids because this project will take you about as long as building a good receiver. Seriously, the amazing supply of cheap integrated circuits available will keep the overall cost low, and will save you considerable time in constructing and designing your computer. Anyway, if you want to build, or have the interest to find out the "why" of the computer . . .here we go!

The Basic Machine

The major circuits making up any computer are shown in Fig. 1. The five basic circuits are the input, output, arithmetic, storage and control circuits. Each one of these circuits is actually made up of many smaller sub-circuits which you will be concerned with building. The five major circuits work together to form a machine capable of accomplishing tasks that are described for it by human operators. The input and output circuits (I/O), provide the means for data signals to enter and leave the computer. The arithmetic circuit performs arithmetic operations on the data signals within the computer. The storage circuits act as the computer memory to store selected data. The control circuits control all the operations within the computer: they control when data is input and output, what and where data is stored, what arithmetic operations are performed, and in general, they keep command of the whole machine. The five basic circuits of the computer are made up of actual electronic components and as such are called the hardware of the computer. Ultimately, all the operations in the computer's hardware are controlled by a bunch of data signals called "words" that make up the computer software.

The software shown in Fig. 1 actually is a group of logic 1 and logic 0's (ground levels and voltage levels) that control the computer through the control circuits in the hardware.



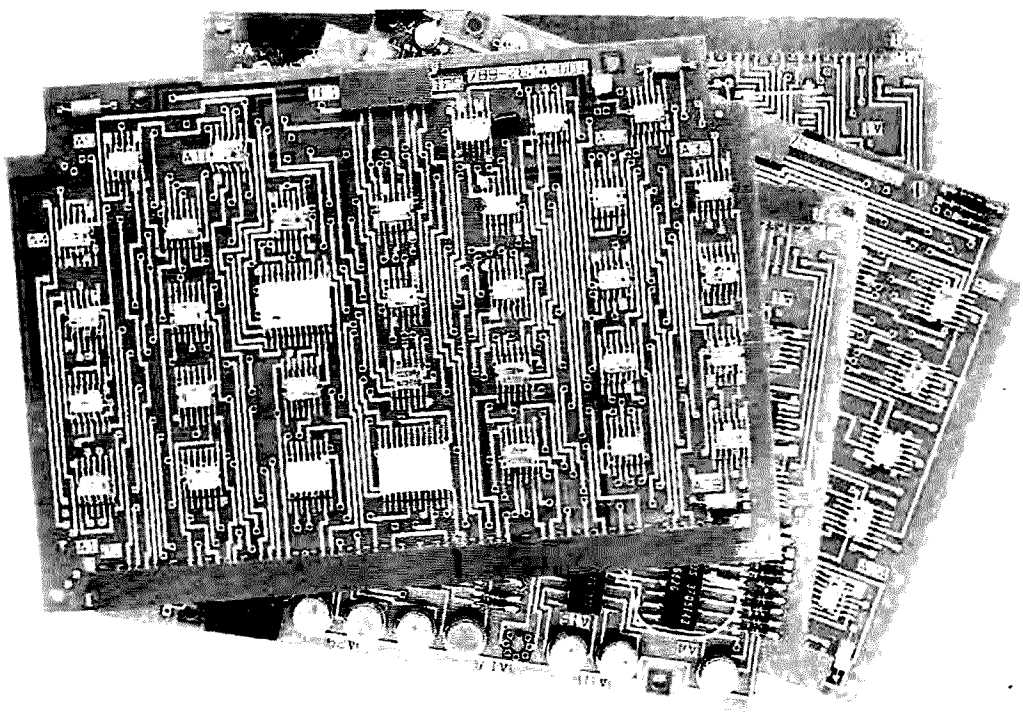


Fig. 1. Typical computer. This is the classical configuration common to all computers. The "software" is actually data (words) that control the operations in the computer via the control circuits. Actual circuits in the computer are the "hardware."

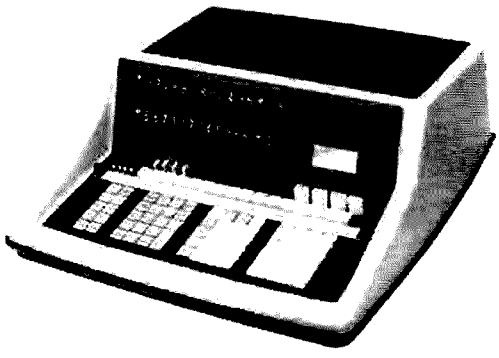
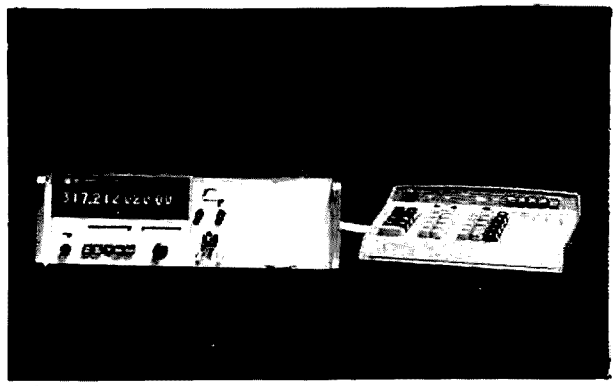
The software allows you to program the computer to carry out desired tasks such as calculating antenna length, etc. We must merely know how to arrange the logic 1 and logic 0 bits into groups so we can talk the machine language. Of course, if the computer is big enough, we can build in an interpreter to allow us to talk to the machine in English. (One such interpreter is the famous FORTRAN COMPILER that I'm sure you've heard of before. FORTRAN stands for FORmula TRANslation; this means formulas are translated to the machine language.) You will have to go to the trouble of learning to use our machine's language unless you want to write a compiler for it after you've built it. Actually, you will merely write down the words that perform a task in your machine and use this as a reference for programming. (Even the pros use a "program reference manual" to translate, since languages get more than just a little complex!) Well, now that we have some background, let's consider building.



Major Construction Considerations

Armed with the basics of computer operation let's consider some of the factors that will war against our construction. Probably the major factor to consider is packaging. You may not want your little jewel to take up half your hamshack or most of your bedroom! Consider some of the little monsters shown in the photos. These computers range from everything from a job that is contained on four circuit cards to a magnificent machine that would consume my house or yours! Consider the approximate size of your proposed machine. Don't limit yourself to a 3x5x7 minibox, but don't envision a monster consuming four or five 7-foot racks either. You'll want the machine large enough to be easy to service, but small enough to move across the room without calling in Allied Van Lines. Don't buy a box and then try to fit in the components. First get a feel for how large and how many circuit cards there will be, then buy a pretty box.



Speed and size of memory will become primary considerations in planning your machine. Read this whole article first, then figure out how much memory you want, what kind of speed to shoot for, etc. Speed and size of storage will both tend to be factors in the size of your machine. Higher speed generally means smaller circuits, shorter interconnecting wiring, etc. and a general overall reduction in size. Larger memory generally means more circuits and a bigger machine.

Collin's Radio company's Micro-Minicomputer. The mini is used throughout this article as a reference to describe computer circuits. This mini has a 16 bit word and a 4096 word instruction read only memory.

The Wang 700A -- a powerful desk top calculator with 8,192 bits of memory organized as 120 storage registers. Programs for the calculator are stored on magnetic tape cassettes.

The Hewlett Packard Computing counter performs sophisticated analysis and doubles as a desk top calculator with the counter input serving as one of the variables.

Price would undoubtedly be a consideration. For many of us, price may be the first consideration! This could possibly be the main reason you would like to build your computer instead of buying. Anyway, here's the scoop; a fairly decent used computer will generally cost you about $10,000. One can buy a little minicomputer from one of the electronics companies for about $3,000. My estimate for the cost of a simple unit that every ham should have in his shack places the price under $200! If you have a full junkbox or you work for a company that offers employee discounts and surplus component sales, you can cut this price considerably. It's obvious, however, that you will have to spend some money on this project to obtain some specialized parts.

Parts for the project are readily available on the discount semi-conductor market or as aforementioned discounts or company stock surpluses. You will definitely have to buy some of the parts at regular prices unless you want to make the major circuits from samll-scale integrated circuits rather than from large and medium-scale integrated circuits. You can fabricate any of the circuits from discrete components. Keep in mind that, unless you have the parts on hand, building each flip-flop, etc. will increase the cost of the project, and using discrete components will definitely increase package size.

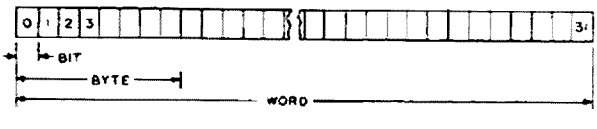


Fig. 2. Large computer, typical word. The computer word is broken down into data "bytes" as explained in the text. The bytes are further broken into their respective data "bits." The "home brew" computer is 'byte oriented" to the extent that registers are 8-bits (one byte, or character, long).

Circuit Details

Now let's look at the individual circuits of the computer and see if we can point out any other construction problems. When you begin to understand how the circuits within the computer function, you can more fully understand the overall operation of the machine. First, we will give a basic description of the circuits, then go into the details.

Input/Output

The input/output circuits (I/O) carry the data signals to and from the computer and the peripheral device. In most ham shacks, the peripheral will be the shack's teletype machine. The input/output circuits must provide buffering for the data signals to and from the computer. To buffer data, you must simply store enough of the data to allow the computer to take data when it is ready. If the data signals entered the computer before the computer needed the data, the result would be a very confused computer and an even more confused operator.

In order to buffer, the input/output circuits will have to store at least one complete teletype character. In fact just one TTY character would be called a "byte" (pronounced bīt) in computer language, because the byte is the lowest number of data bits capable of storing a complete character. A data word would be a group of bytes just

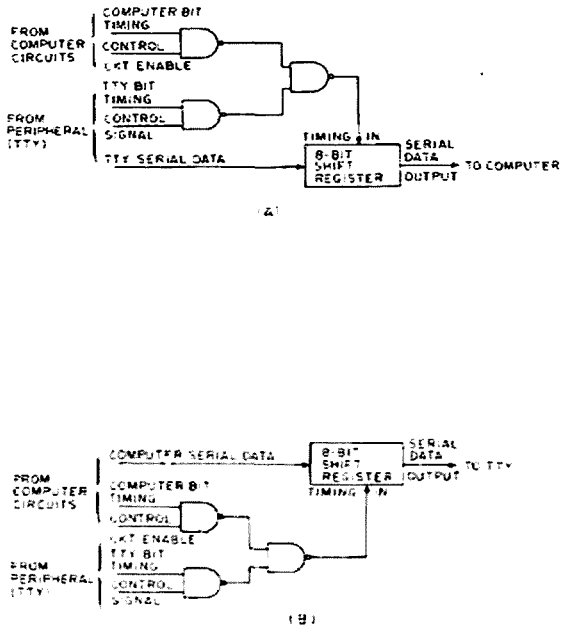

Fig. 3(A & B). I/O Circuits. Fig. 3A shows the computer input circuits. Data from the TTY enters the register under TTY control. This data is stored until "computer timing" drives it from the register under program control (control CKT enable).
Fig. 3B shows the computer output signal. This time the computer enters and stores data and the TTY removes the data at TTY timing rates.

as a byte is a group of bits. The word can be any number of bytes; in most computers a word contains at least four bytes as shown in Fig. 2. In our "mini" a word will contain only one byte.

You must make the I/O circuits in your computer capable of storing a data word. Since a word and a byte are the same in this machine, the word will be 8 bits long. Thus your computer can affectionately be called an "8-bit machine." Now it is obvious that we must devise a circuit that is capable of storing 8-bits of data. The data must load into the input circuit at a timing rate determined by the peripheral (TTY), and the data must be taken out at a timing rate determined by the computer. The opposite must happen in the output circuits, that is, the data must load in at a computer rate and read out to the peripheral at a peripheral rate. Take a look at the circuit shown in Fig. 3. This is the input circuit to a commercially produced minicomputer altered somewhat to make it compatible to our requirements.

Notice how the TTY CONTROL signal controls the entry of the TTY timing signal into the gate which clocks the register. The TTY CONTROL signal could be generated by a circuit which detects the depression of a key on the TTY. The TTY TIMING signal is one that occurs at TTY bit times and each bit of the TTY signal is clocked into the machine. When the STRF (store) signal goes high, the computer's internal timing reads out the signal stored in the byte register. This signal is routed to the control circuits (Fig. 1) and the control circuit will decide what to do with it, i.e.; whether to store the signal, process it in the arithmetic circuits, or to ship it on out to the output circuits. The selection of what's done with the signal depends on the program of the "software" shown in Fig. 1.

Arithmetic Circuits

The arithmetic circuit provides arithmetic and logical operations on the data signals within the computer. Upon command of the control circuits, the arithmetic section of the computer can ADD Logical OR, Exclusive OR, or Logican AND any two data signals. Some computers can multiply or divide directly in the arithmetic circuits, our computer will not offer this "hardware multiply/divide." If you want to multiply, you'll have to add again and again. If you want to divide, you are going to have to learn two's complementing and take it from there.

The arithmetic circuit mostly consists of simple steering of data signals through the gates that will perform the appropriate operation on the data. Figure 4 shows the arithmetic circuit recommended for our computer. It is simple, straightforward, and easy to troubleshoot. Probably the main thing in its favor is that it is cheap! The inputs marked CONTROL INPUT come from the control circuits. These inputs are ultimately controlled by the program (or software).

If you use this circuit, you should be able to contain the entire arithmetic circuit on one card. This will greatly aid you in troubleshooting and construction. The adder can be most any full adder which is compatible with the logic you use. If you are using RTL or compatible TTL you might try the MC796P for only a shade over $5.00.

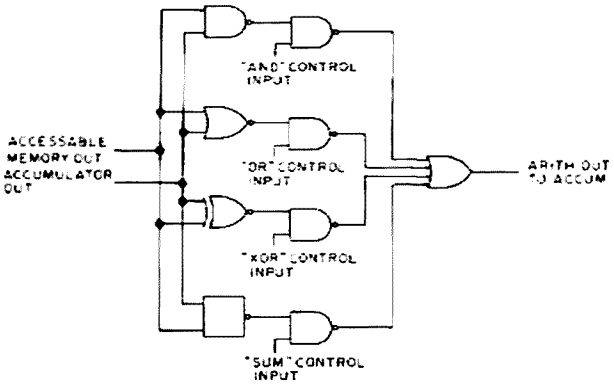

Fig. 4. Arithmetic circuits. The output of the workable storage memory (accessible memory), and the accumulator are combined in AND, OR, EXCLUSIVE OR, or ADDER. The gated data outputs are chosen by the various control inputs from the control circuits. These control signals are generated in the computer program.

This is much cheaper than you can build one yourself. Since this particular unit is a Dual-full adder, you will have a spare: this is a good policy because it's just like buying an extra fuse. By the way, if you want to hardware subtract, you can add the MC796P; two full subtracters (same price as the 796). Of course, there are many adders and subtracters on the market. Be sure to select one that is compatible with the type of logic you are using, i.e.; TTL, RTL, ECL, etc.).

Storage Circuits

There actually are many storage circuits within the computer. These circuits store instructions or data in the computer and allow the computer to use the data or instructions at some later time. Your log is a "storage area" and stores information regarding your past QSO's. One example of a storage circuit is the input/output circuits already mentioned. The data input (or output) is stored until the computer (or peripheral) is ready to use it.

Storage circuits within the computer are usually classified to their degree of importance. In reality, one is just as important as the other in overall operation, but we order their importance in the same way that we consider the fuse less important than the overall transmitter. Yet we know that the fuse can mean the difference between the transmitter operating or not.

In our small machine, we have three levels of storage or memory: main memory which stores the software and the programs that make the computer carry out a desired function; workable memory which allows for semi-permanent storage of data while an operation is performed; and temporary memory which includes all temporary storage such as the registers in the input/output circuits. First, look at some main memory systems and decide on some version to use in our computer.

Main Memory

The main memory must store the computer program along with the software (called the operating system) that tells the computer when to do what thing. The simplest main memory would be a shift register that is fed from the peripheral with the program, and then stores the instructions until the computer has need to read out an instruction. Assuming your computer was to have a limited number of instruction words, this shift register memory would probably work rather well. However, keep in mind that the computer does things in very minute steps and you will see that you must be able to insert many instructions into the machine to

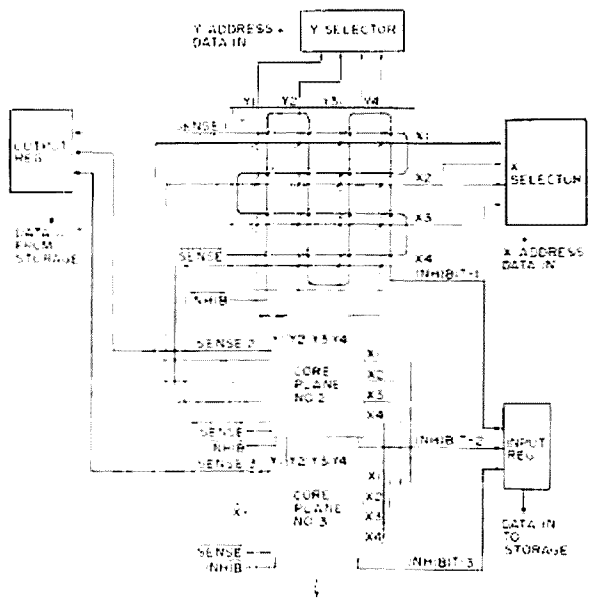

Fig. 5. Core-Main memory. This core memory will store 3-bit instruction words or data words. Instruction words are stored in "protected" areas of core. Workable areas of core will be used as temporary storage for program-selected data. These areas of core work as 'accessible memory."

perform a relatively simple task. This would mean many shift registers and lots of money. Enter, the magnetic core memory. The magnetic core memory saves the day for us. Cores are cheap, reliable, and easily obtained. They have their problems though, the cores are extremely small and are very sensitive to temperature changes and not normally as small or as fast as shift register memories. Core memories basically consist of a matrix of magnetic cores. The cores are addressed by selecting X and Y coordinates. The X and Y lines are pulsed and the cores selected and magnetized. Cores magnetized in one direction equal a logic 1 and cores magnetized in the opposite direction equal logic 0.

Figure 5 shows a section of a simple core memory. The currents in the X and Y lines are called the half-select currents. Two times the current flowing in either the X or Y lines is required to saturate a core. With half the select current in each of the X and Y lines, only the cores that appear at the intersection of the X and Y lines will be saturated. All the X and Y lines feed all core planes as shown in Fig. 6. A specified X and Y address will find the intersection of the same core position in each plane. The two half currents

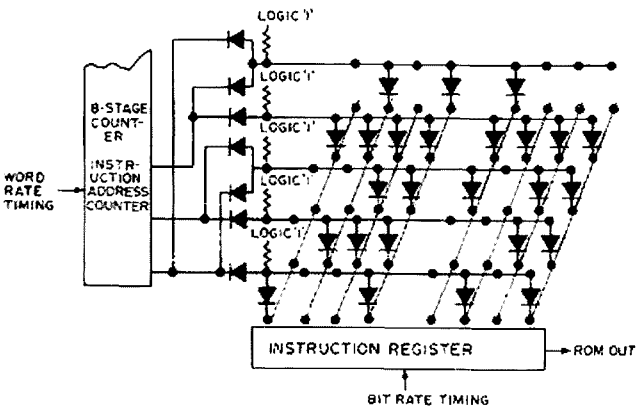

Fig. 6. 256 Bit rom (partial drawing). Contrasting the core memory, the read only memory (rom) provides instruction outputs. The instruction word is formed by the diodes. Where a diode is present a logic 1 will be stored in the instruction register. Note that if you are using an instruction register which is clamped by its SET input you will have to add a pulse-forming network on the SET input of each stage. Also if your register needs logic "0" to set, reverse your logic. The diodes on the 8-stage counter insure a "word 1,2,3,4,5. . " count.

(X and Y) will switch the core in each plane to logic 1. Note that for any one X and Y drive line, the same position in all three core planes will store logic 1. The inhibit signal causes the selected core to store logic 0.

To read from the cores, the X and Y read addresses are chosen, and a half current in each (opposite of the write current) switches the addressed cores in each plane to logic 0. If the core is presently a logic 1, the sense line for that core plane will feel an output pulse. If the core is at logic 0, there will be no output.

The read action causes the core to switch and the stored data changes. This is called a "destructive read" because the stored data is lost. To compensate, the computer rewrites the data back into the core, while the X and Y addresses remain the same. Thus, core memories have a "write after" cycle to keep data from being completely lost.

Your problem as the builder, is to incorporate the write after read cycle and the bi-directional drive currents to the core. The write after read cycle can be hardwired into the machines timing circuits. Integrated circuits can be had that will supply the bi-directional drive currents for the cores.

Finding the cores is actually easy. One can obtain 14x16 bit core planes in a 5-plane stack from Herbach and Rademan Inc., 401 East Erie Avenue, Philadelphia, Pa. 19134. The price for an IBM surplus stack is only $24.95. One of these little jewels would provide a dandy start for your computer, and you could add a stack as you could afford it.

There is one more type of main memory you might consider; the read-only memory. The read only memory can be a simple, diode matrix arranged to form instruction and data words when pulsed. It would take a lot of diodes to work (maximum of eight per instruction). For 8-bit instructions and about 144 instructions in all, it could take a maximum of 1152 diodes! Sounds bad, but you can buy 1000, 1N34's (which should be OK at our slow speeds) for only $19.00 from B-A. If you decide to go the read-only memory (rom) route, you will have to wait till you decide on some control circuits before you build the rom. This is because you program the thing when you build it

and you'll have to know the capabilities of the machine.

The disadvantage to the rom is that it reads only. In order to change the program, you'll have to rewire, or make another rom. The average ham might go with the rom, because it will be cheaper in the long run since there are no special circuits or two-directional currents to switch. By building several rom's on separate cards, you could change programs merely by swapping rom's. Later, you could add a core memory, or even a solid-state job if you wanted. Figure 6 shows a portion of a typical rom. This will give you an idea of what you'll need and the control circuits will tell you exactly how to organize the memory.

Workable Memory

My only recommendation for a workable memory would be a shift register. Of course, if you use a core memory, you can merely use portions of the core memory for workable memory. Several shift registers would be arranged to be accessed as data registers. These registers would be designated "data register 1,2,. . .etc." Figure 7 shows the workable or "accessible" memory that is used in the example computer. Access to the registers in the accessible memory is provided by the control circuits and thus, the computer program.

The accessible memory will be used to store data from the main memory input signals, data to be output, or the combination of signals from the arithmetic circuits. The registers can feed data from their output back to the input to allow us to rotate, or move the data within the register by any number of bits as selected by the program or to save data signals.

Temporary Memory

The temporary memory will provide temporary storage of data until the data can be transferred to other registers or circuits within the computer. An example of a temporary memory is the register in the I/O circuits. Another is the Accumulator Register in the example computer. This register merely accumulates data from other sources for one operation of the machine. The accumulator is merely a byte-long register and is only shown in the block diagram, Fig. 14, because of its simplicity.

That is about all that can be said about memory for your machine. It is your decision as to whether to use a core memory or rom for main storage. Keep in mind that in the example computer herein, an rom is used. Lets go now to where the circuit hardware first meets the software – the control circuits.

Control Circuits

The control circuits actually make the rest of the computer operate. This is where the commands that you insert in the program are decoded and changed to enable signals that control other parts of the computer. Figure 8 is a block diagram depicting the control circuits and their function. Note that circuits within the computer are input and output selectors that route data signals to and from various registers within the machine.

The hub of the control circuits is the instruction decoder. Instruction inputs from the main memory enter the instruction decoder and become commands to the computer's gating circuits. The gating circuits are: the accumulator input selector; accessible memory input selector; accessible memory/accumulator output selector; arithmetic circuit input selector; input and output circuits; and the timing circuits. All the gating circuits are similar to the gating

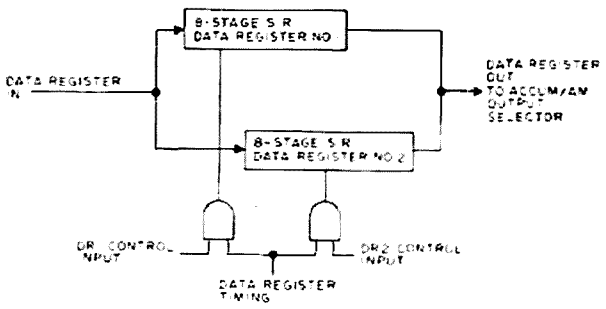

Fig. 7. Accessible memory. The accessible memory provides workable storage when rom is used. It also provides temporary storage if you use main core memory. The accessible memory is made up of two 8-stage shift registers (DR1 & DR2). Inputs and outputs to these "data registers" are parallel. The data registers are selected by the program via the control inputs. The control inputs route timing to the selected register.

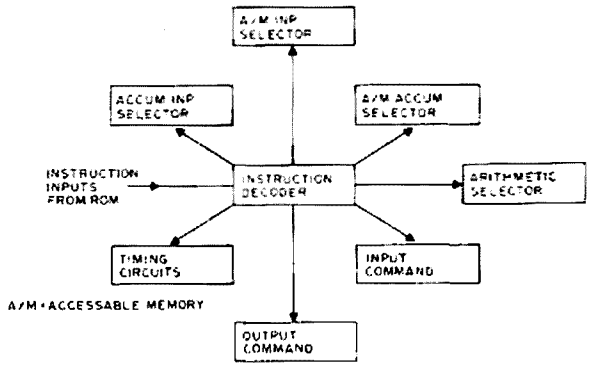

Fig. 8. Control circuits. The control circuits interface the human programmer and the machine. The instruction words from the rom are programmed by the programmer. These words are decoded by the instruction decoder. The many outputs from the instruction decoder go out to control data to/from registers, operations in the arithmetic circuits, data to/from peripherals, etc.

circuits in the arithmetic section of the computer. That is, the instruction decoder supplies the enables and the gating circuits do the routing of the data (see Fig. 10).

The instruction decoder is made up of two major portions, the instruction storage register, and the decoding circuits. For clarity, Fig. 9 shows only a portion of the instruction decoder (the other part is in Fig. 10). The instruction reads in from the main memory and is stored in the instruction storage register. The parallel output of the instruction storage register is decoded in the instruction decoder. The outputs from the instruction decoder are the logic 1 or logic 0 levels that control the computer circuits.

It is the input from the Main Memory (rom in the figure) that determines the actions that take place in the computer. The arrangement of the logic 1's and 0's in the instruction word, control all circuits within the computer. Remember, core or shift register memories have the program inserted by the operator at the same time the machine is programmed. With read-only memory, the program is inserted when the rom is wired.

The instruction decoder is made up of two "one of four" and one "one of 16" decoders and their associated gates. The gates shown in the diagram are not hardware gates. The gates are the logic symbols and you will have to use combinations of AND and OR gates in order to achieve these logic functions. Let's look over the various circuits in the decoder and find their functions within the machine. At this point, we will look at the hardware and the software in such a way that you may have trouble telling which is which. Just remember that the hardware pertains to the circuits doing the decoding and the software is the word being decoded.

The first two bits from the storage register are decoded by a one-of-four decoder. This means that the four combinations of the two input bits are decoded to achieve one of four possible outputs at any one time. Thus a 0,0 on the input will drive the ACCUM output to a logic 1 (note: you will need to invert to get this from an IC). This selects to send the output of the accumulator to some selected circuit in the computer. A 0,1 input (decimal 1) enables the output called DR1, this is Data Register #1 in the two-register accessible memory. Likewise, a 1,0 (decimal 2) enables the output which controls Data Register #2. The 1,1 output (decimal 3) is not used.

The next two bits of the instruction word control three things: rotation of data, rom output to accumulator, or data register end

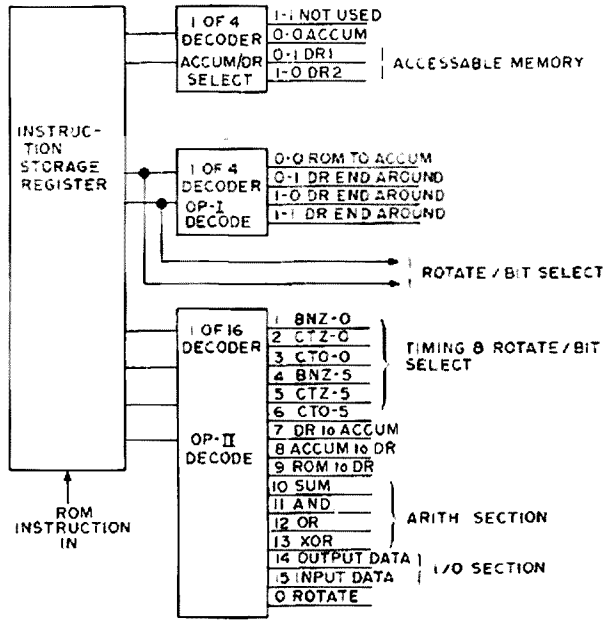

Fig. 9. Instruction decoder (simplified). The instruction decoder provides outputs which control the computer functions. The one of four and one of 16 decoders may be fabricated or may be purchased as MSI circuits from Fairchild.

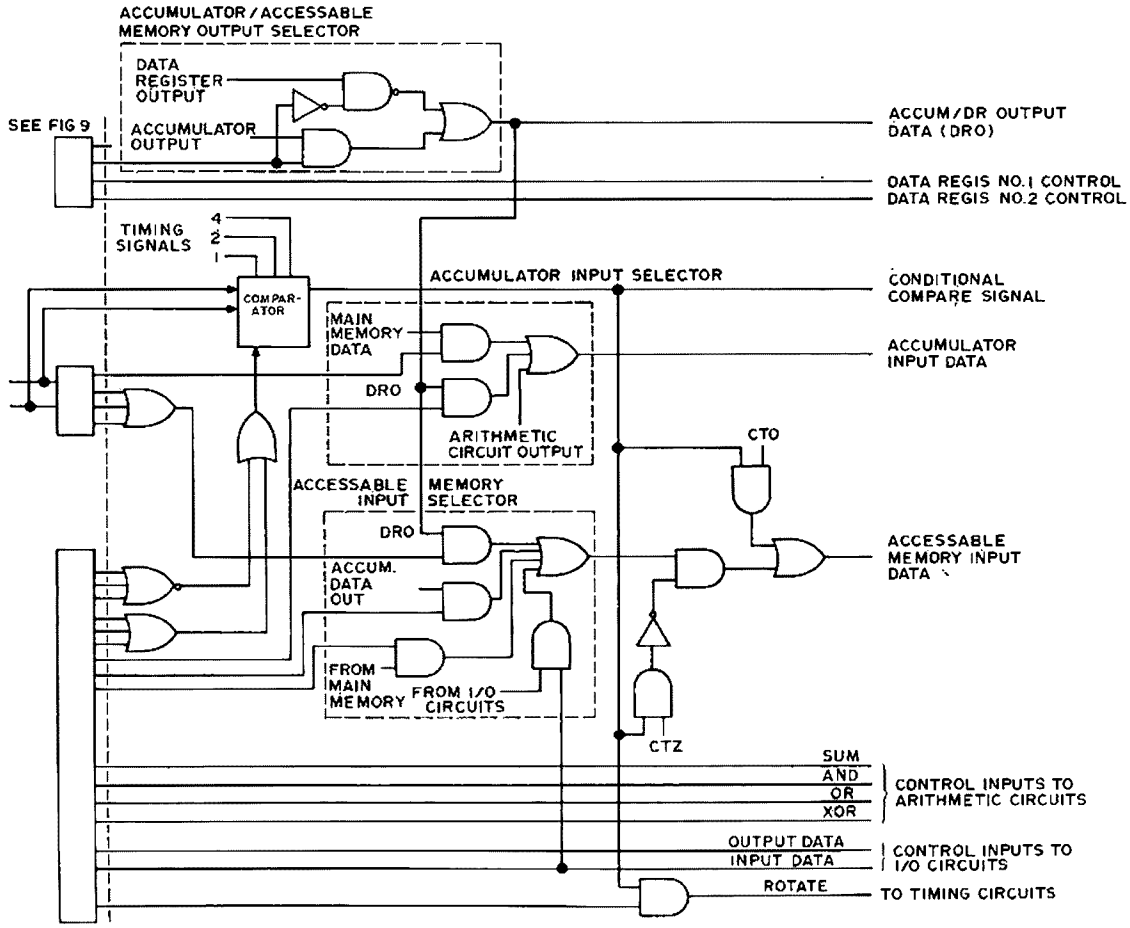

Fig. 10. Instruction decoder. The instructions (Fig. 9) cause outputs from the circuits pictured here. These outputs are switched data signals or control signals as shown.

around. The next four bits of the instruction word actually control operations within the computer. From the block diagram, Fig. 8, these outputs feed the arithmetic operations circuits, accumulator register inputs, data register inputs, and input/output control circuits.

Figure 10 shows the remainder of the control circuits. Primarily the rest of the circuits merely gate the various outputs from the instruction decoder. These circuits should easily fit on their own, separate printed circuit card. Since there will be many actual data signals routed through this card, take care to isolate each data signal with a power or ground lead on the card if possible. This should eliminate many problems caused by feed through of data.

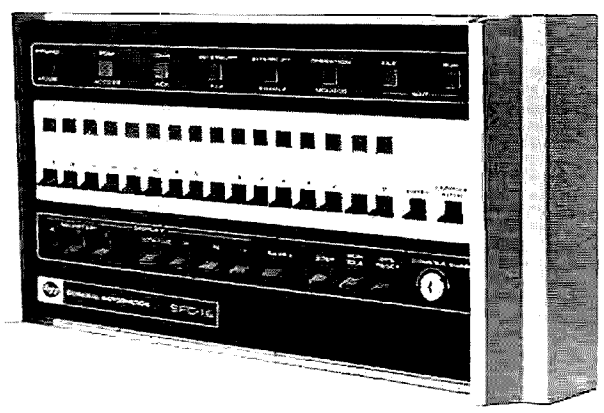
Actually, the operation of these circuits is obvious by taking a close look at the logic. For instance, the ACCUM/AM OTPUT SELECTOR (accumulator or accessible memory output selector) uses the first output from a one-of-four decoder to control the data output called DRO (data register out). When the control signal from the decoder is a logical, the AND gate is enabled and ACCUM (accumulator) output data is routed out to become DRO. Under the opposite condition, the AND gate is disabled and the inverter allows the DRO signal to be formed by the data register output.

A little explanation is necessary to understand the purpose of the comparator. The comparator works on inputs from the instruction decoder and the timing circuits to provide an output that is a function of time. When the instruction decoder decodes a binary number, this number (between 0 and 7) is applied to the comparator. The first two bits of the three come from the 3rd and 4th output of the instruction storage register. The third bit comes from the one of 16 decoder and indicates whether a branch or clear instruction is greater or less then 4. Note: since there is no third bit in a rotate condition, you can rotate data only a maximum of three bits per computer operation.

When the timing signals enter the comparator match the binary number on the other three inputs, the comparator will have an output. This output will be used to check a data bit (branch), change a bit to 1 or 0 (clear), or move the data within the accessible memory (rotate).

Be sure to study this part of the computer carefully. These circuits are your interface with the machine. When you want the computer to do something (other than just sit there, of course) you must tell it to happen in the control circuits. Thus the control circuits will determine the word structures that you use in writing a program (and wiring the rom, if you go that route).

Timing



Timing for the computer is very important. Timing allows the computer to operate properly by controlling the sequence of events that take place in the computer. Various timing signals must be provided, some of which are; word and bit times, and cycle times. Word and bit times are self explanatory; bit times are the fastest, and word times are made up of a number of bit times (8, in this machine). Cycle times are a little weirder, and may require some further explanation.

Your computer will operate in up to three cycle times: two, normally, with a third added if certain conditions are met. The two main times are the instruction read and the instruction execute cycles. During the instruction read cycle, the instruct on word reads from the rom and is decoded. During the instruction execute cycle, the decoded instruction is executed, or performed. For instance, the instruction read cycle may bring in an instruction that tells the computer to ADD two signals. The two signals will then be added in the instruction execute cycle.

If an instruction is a "branch" you generate a new timing cycle. If the decision to branch is positive, the rom puts out a literal word which loads into the accumulator. Then the word is dropped into the instruction address counter. Thus the next computer instruction comes from the rom at the place specified in the literal "branch to" address.

In case you haven't already guessed, the three cycles must be at least a word long. In fact, for insurance, and because this computer isn't going to be the fastest thing on earth, the cycles will be two words long. The actual operations will take place on the first word and the circuits can more or less "settle in" during the last word. This feature will also allow you to increase your machine's capacity to a 16-bit word sometime with little modification to the timing circuits.

You'll have to be fairly careful in laying out the timing circuits. You should come out all right if you remember to follow the rules on IC spec sheets, such as tying all unused J and K's to logic 1. Board layout won't really be critical unless you decide to make your machine run at high frequencies. Try 100 kHz basic oscillator frequency. Do decouple the power leads into the card and tie them to the front of your power bus. These measures will help keep the timing on

General Automation's minicomputer with a 16 bit word and a 4K expandable memory, does operations less than 1 ms.

The IBM 360/195 – the largest computer in IBM's line. This machine can process an instruction in only 54 nonoseconds.

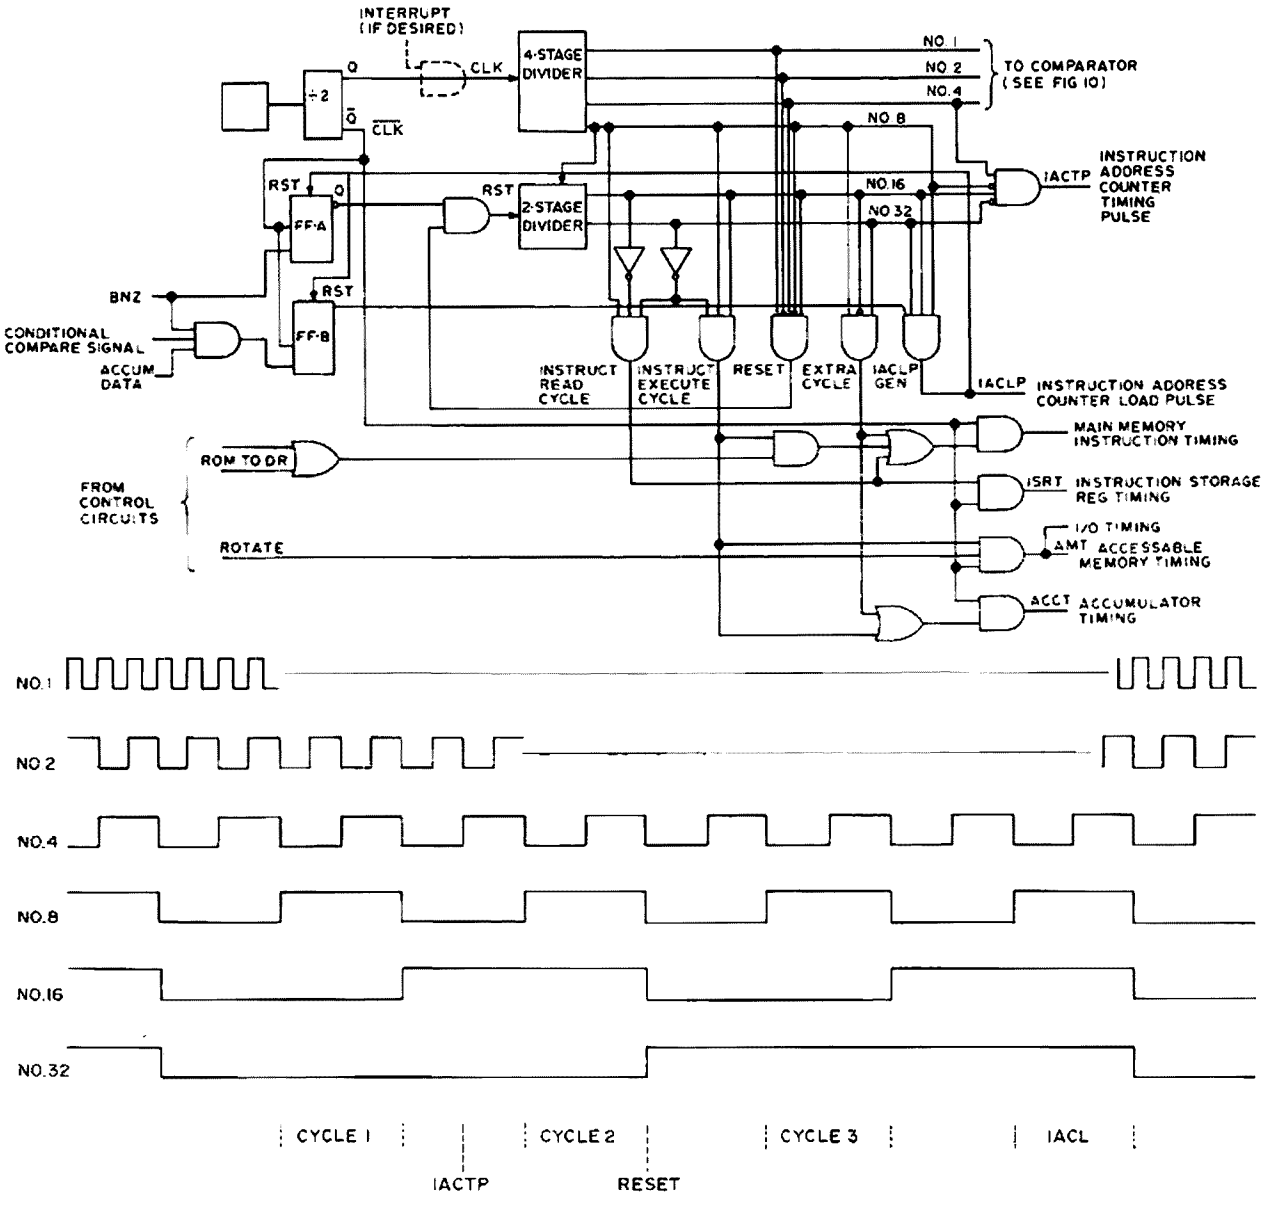


Fig. 11. Timing circuits. These circuits provide timing to the various computer circuits at the proper sequence. When the command is a conditioned branch, and the condition is positive FF-A forms a new timing cycle (see text).

the timing card only, except where you run a wire out.

The circuits shown in Fig. 11 are based on operational circuits. Stick closely to the recommended logic and you should have your timing circuits working a lot faster. If you have good working timing circuits, you will have your computer up and running in a lot shorter time.

Roughly what's going on in Fig. 11 is that timing is generated by the 100 kHz oscillator and divided by the frequency dividers, down to word length. The word length outputs are gates to form the cycle signals. The timing diagram in Fig. 11 explains the operation of the circuits overall.

The 4-stage divider output signals are applied to the comparator in the control circuits to provide a time variable signal. These signals are also used in combination with the 2-stage counter outputs to provide the cycle timing intervals. Notice that if the reset output is not inhibited at the input, it resets the 2-stage counter after the instruc-

tion execute cycle. A branch command cuases flip-flop A to inhibit the reset and thus a 3rd timing cycle begins.

Also during the branch command, the IACLP (instruction address counter load pulse) is generated. This signal loads the output of the accumulator into the instruction address counter if the branch decision is positive. Thus because of the action of flip-flop B, the computer will "skip" as many steps in the program as was determined necessary by the programmer.

The IACTP is the instruction address counter timing pulse and it occurs just before the instruction execute cycle so the next instruction will read from the next memory position. The pulse was placed here so that if the instruction word said the next word was a literal to be placed somewhere in memory, the word could read in during the instruction execution.

Software and Programming

Software and programming for this computer go hand in hand since you are the builder. The software controls the computer s overall operation. The program controls the computer in a specific problem solving task. The differences between software and program are a little confusing, since the "whole works" of instruction words and all are called the computer's software.

By now you should have a pretty good idea of how to program your computer. If you haven't, refer to the section on the control circuits again and you will. To program the computer, you must know the task you need to perform, then you must generate the instructions that will accomplish this task.

Symbols have been designed to aid you in programming. These symbols are arranged to form a flow chart, or step-by-step picture of the computer's operation. Different flow chart symbols represent different functions just as different schematic symbols represent different components. Some basic flow chart symbols are shown in Fig. 12.

Figure 13 shows the flow chart symbols arranged to form a program. The chart shown is only part of a program, or routine that is used to control equipment from a TTY. This portion of the complete routine is

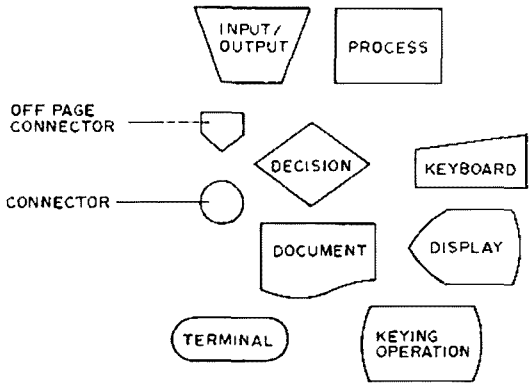

Fig. 12. Flowcharting symbols. The programmer uses these symbols to draw a schematic diagram of the tasks to be done to accomplish an end task. This "schematic" is then used as his reference to complete the programming.

called a subroutine because it performs a complete function within itself. The subroutine shown scans the input circuits again and again to see if a data word has been entered from the TTY. The figure is completely self-explanatory.

Software Meets Hardware

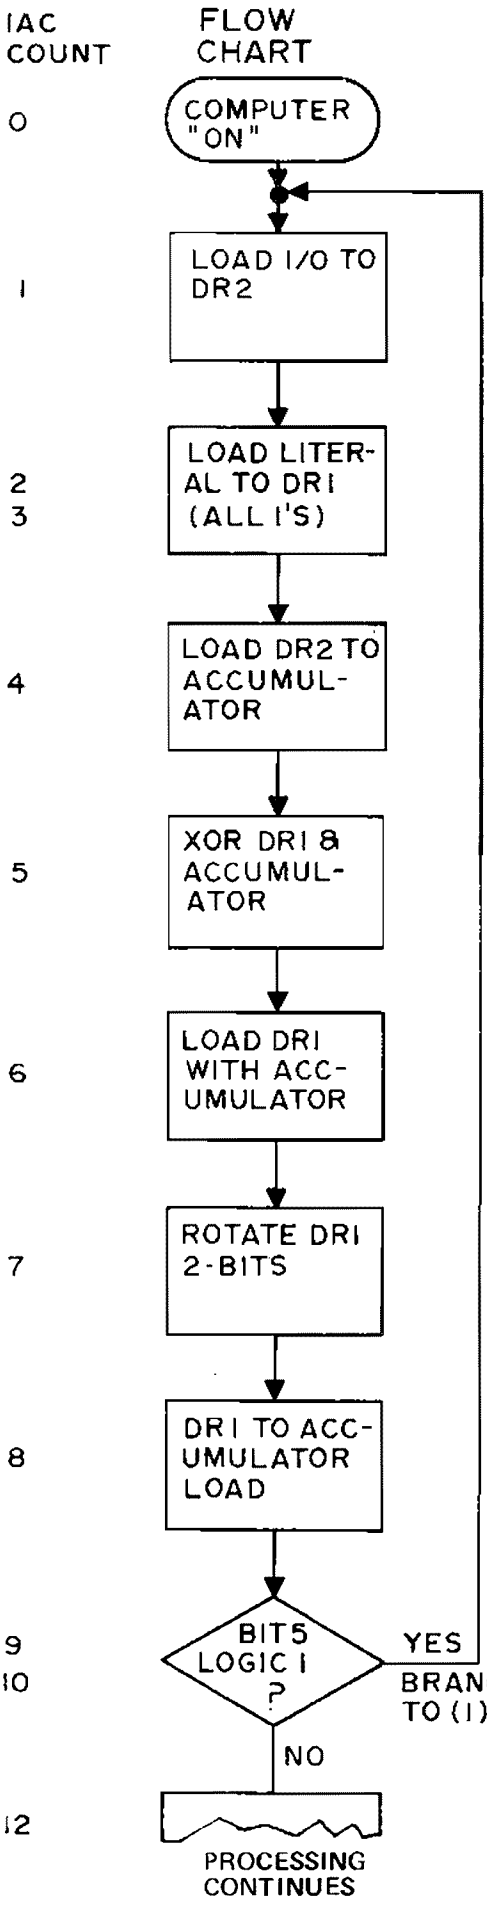

Figure 14 is a block diagram of the completed computer. You will use this block diagram when you program the computer to keep track of the data floating around in the machine. The machine in Fig. 14 uses an rom, but keep in mind that you may use core. If you use core, it will connect in place of the rom.

Notice how the accumulator register is shown. The accumulator has 8-outputs that parallel feed the instruction address counter. This is to enable the "branch to" address to load from the accumulator during the third operation cycle. Also note the inputs that feed the accumulator and accessible memory input selectors. Don't forget to send commands from the control circuits to the appropriate selectors.

To find out how the machine works as a complete unit, just refer to Fig. 13 and follow along in Fig. 14. The explanation in Fig. 13 should suffice as an explanation of the computer's operation.

Construction Problems

Wish there would be no construction problems. But for any project of this size, you will have some developmental problems.

1	10101110	This command causes data to read in from the I/O circuits. Note that there may be no data if none was entered.
2	01101001	This command will put the next instruction (a literal) in DR 1.
3	11111111	The literal.
4	10010111	We are moving data in to the accum and sending it right back into DR 2 to have it in both places.
5	01101101	This command will Exclusive Or the DR 1 and Accumulator signals, thus providing an inverted data output.
6	01101000	The inverted data from the arith section is in accumulator and we want to move it to DR 1.
7	01010000	Now the data in DR 1 is moved ahead two bits. Was: 7 6 5 4 3 2 1 0 STOP BAUD X X X X X START BAUD Is: 7 6 5 4 3 2 1 0 START BAUD STOP BAUD X X X X X
8	01100111	Inverted, rotated data is loaded into the accum in preparation for next step in program.
9	11000100	Data is checked for a "T" at bit 5. This means that there was no stop baud.
10	00000001	If no stop baud, the literal loads into the IAC and the program jumps to the beginning and the process starts again.
12	YOUR PROGRAM CONTINUES	If there was a stop baud your program will determine what it is.

Fig. 13. Detailed program. This is the first part of a routine designed to control some equipment on command of the TTY. This particular "subroutine" merely looks for the presence of any data input.

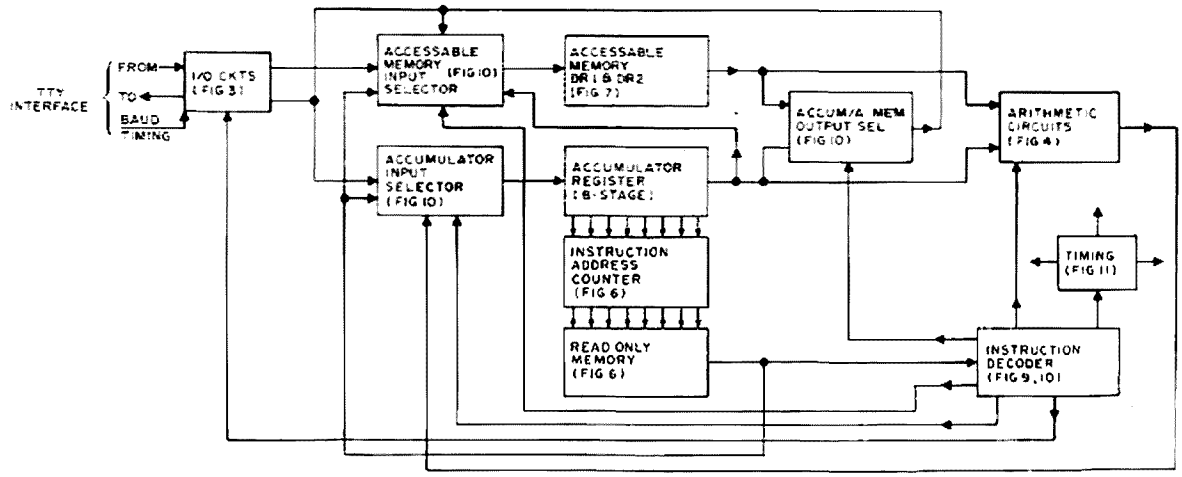

Fig. 14. Minicomputer block diagram. Mix up all ingredients in the manner shown and you have a complete minicomputer! All the action begins when the timing circuits start the count in the instruction address counter. Instruction number 1 tells the computer what to do next via the control circuits. The instruction will be whatever you program into the computer.

Even if you follow a tried and tested design verbatim. Power supply may end up being the most serious problem for you. Use a rule of thumb – overrate. Use a supply twice as large as necessary. And be sure to use power buses. Don't forget to use a common power ground also. This will eliminate many tears and much swearing!

You may wish to breadboard each of the circuits before you print a circuit. It has been my experience that the breadboard and the final version never work the same. I recommend that you design carefully, recheck, check again after a couple of days, then print the circuit. Build the final version first!

Interface Problems

Certainly, you won't be able to interface any or all peripherals with ease. Just choose one type of peripheral and then design for it. You will have to bring in peripheral bit timing to the computer (band rate timing in a TTY). You will have to figure out how to interface the peripheral you choose. A description of peripherals and how to interface them would be enough for a complete article by itself.

Now What?

You've got the computer, or you've got the knowledge that you wanted about how computers function. Now what can you do with this knowledge, or the machine?

First of all, with the knowledge, you can read a few good books and articles and understand enough of what they are saying to learn more. Since you know what basic machine language programming is like, you may want to go on and learn a higher level language or compiler. Finally, you can keep your eyes open for a good used computer and this article will provide excellent reference to aid you in programming and troubleshooting. (Incidentally, a friend of mine picked up a fine used computer for $3000! Don't scoff; he used it in his own little bookkeeping service business and has paid for it, and bought another.) There is a used computer dealer called "The Computer Exchange" which could supply you with price data on a used machine. The Computer Exchange Inc., 30 East 42nd Street, New York, NY 10017, phone 212-661-5870.

If you build your own machine, you can do anything your imagination will allow (the control circuits will have something to say about this too.) There is, of course, a point to what a computer can do. It can't replace your wife, because it couldn't change a baby's diaper. (Never overlook the possibility that you might fabricate a computerized robot that could darn socks or something.) The computer is not an "all solver" for the world's and your problems, but it might make a good sized dent if you're willing to try!

THE MINIMOD

The Minimod is a hybrid modulator for a low-power VHF transmitter of the type using a 3630 in the final. Since there is a B+ line present in the transmitter, the back end of the modulator has tubes, while the front end is transistorized to save on power consumption and cut down on heat dissipation.

The 2m rig used consists of a two-tube exciter and a 6360 running 12W input, modulated by the minimod. The whole rig is built into a box 8¾x5x5 in.

Circuit Description

The mike is coupled to the first transistor through a blocking circuit. The capacitor across the input socket shorts out any rf that tries to get into the modulator through the input socket. The coupling capacitor blocks the dc, and the series resistor acts as a choke to any rf that may get past the decoupling capacitor and as an impedance in series with the transistor.

The first two transistors form a dc feedback pair. These have very high gains, so that the first one (an emitter follower) presents a high input impedance. The high impedances in the input match the crystal mike used to generate the audio. The second transistor is a common-emitter amplifier directly coupled to the first transistor. Bias for the first transistor is obtained from its collector through a high value resistor.

The audio is capacitively coupled to the gain control and on to the second dc feedback pair. This second dc feedback pair consists of a common-emitter amplifier with negative feedback followed by a phase splitter. From the phase splitter the audio is passed to the grids of a conventional push-pull tube output stage.

Supply voltages are obtained from the main B+ line, with resistors used to drop the B+ to a suitable value for the transistors.

The second dc feedback pair has a supply voltage of about 50V so these

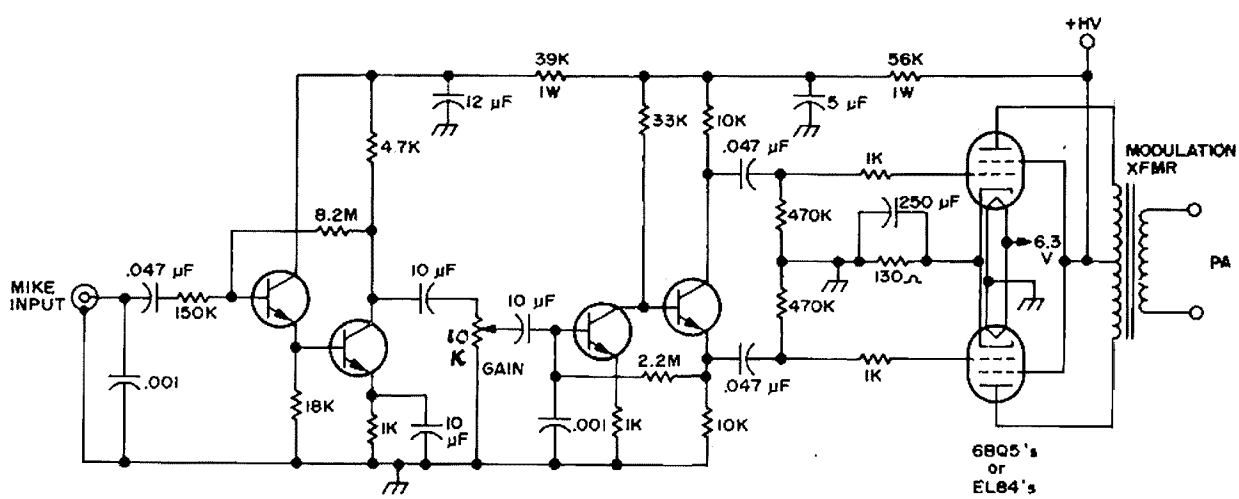

Fig. 1. Minimod schematic.

transistors must have a high collector breakdown voltage.

Construction

The main chassis has to be drilled to mount the tube bases and modulation transformer or a subchassis can be mounted in a suitable place. The transistor circuitry is built on a piece of laminate board. Its construction is not critical as long as care is taken to avoid picking up rf. The leads to the input socket and gain control are made up of shielded cable grounded at one end.

The capacitor at the input to the second dc feedback pair is to decouple any rf picked up on the leads to the gain control.

In the prototypes, the B+ was 280V, the phase splitter had a supply of 50V, and the front end 10V. Although the dc feedback pair is very tolerant with respect to supply voltage variations, should the B+ be much higher than 300V, the value of the first dropping resistor will have to be changed. The new value can be calculated using Ohm's Law.

The transistors used in the first dc feedback pair are a pair of 2N2926Gs. The second dc feedback pair uses transistors designed as Nixie drivers. Any type will do provided that their collector breakdown voltage is of the order of at least 80V.

By using dc feedback pairs, the circuit compensates itself for any change of transistor parameters, allowing type substitutions to be made.

The modulation transformer has to match into the final. The match is fairly critical; therefore, for best results choose a transformer that matches the final, although any old transformer will give *some* results.

Results

I have had constant reports of good modulation depth, and good sound, while using the minimod in my subminiature 2m rig. No particular shielding has been built around it and it does not seem to suffer from rf breakthrough.

I would like to thank G8BEH for his help in developing the minimod, and for his patience in the testing.

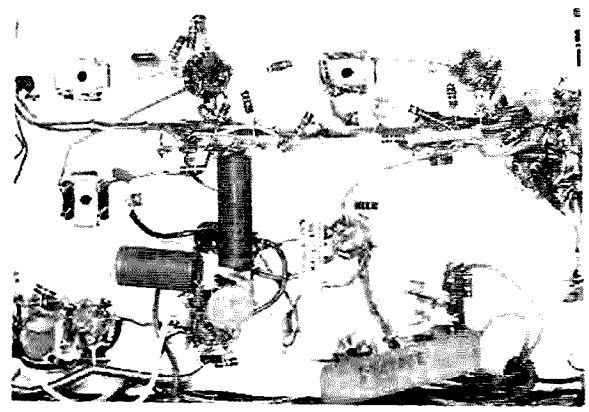
UPDATE YOUR HEATH HR-10

Murray Ronald VE4RE
Box 974
Brandon, Manitoba
Canada

Among new amateurs the Heathkit HR-10 receiver is a very popular receiver. However although it does a good job on AM signals, its performance on CW and SSB leaves some margin for improvement. One of the problems is the lack of avc action when copying CW or SSB signals. Also the lack of regulated voltage on the local oscillator-mixer and bfo tubes results in some instability on the high bands. The modifications which follow correct these problems to such a degree that it will not seem like the same receiver. The addition of the audio-derived avc brings about the most startling improvement. With the rf gain fully on, copy is excellent on CW and very good on SSB except on very strong signals – all this with the existing detection system, too!



The modifications are not difficult or costly to make. With a little diligence the parts can be purchased for $10 or less. The changes can be easily incorporated when the kit is assembled. In fact, a new kit with these modifications represents real performance for your money.

Power Supply Modifications

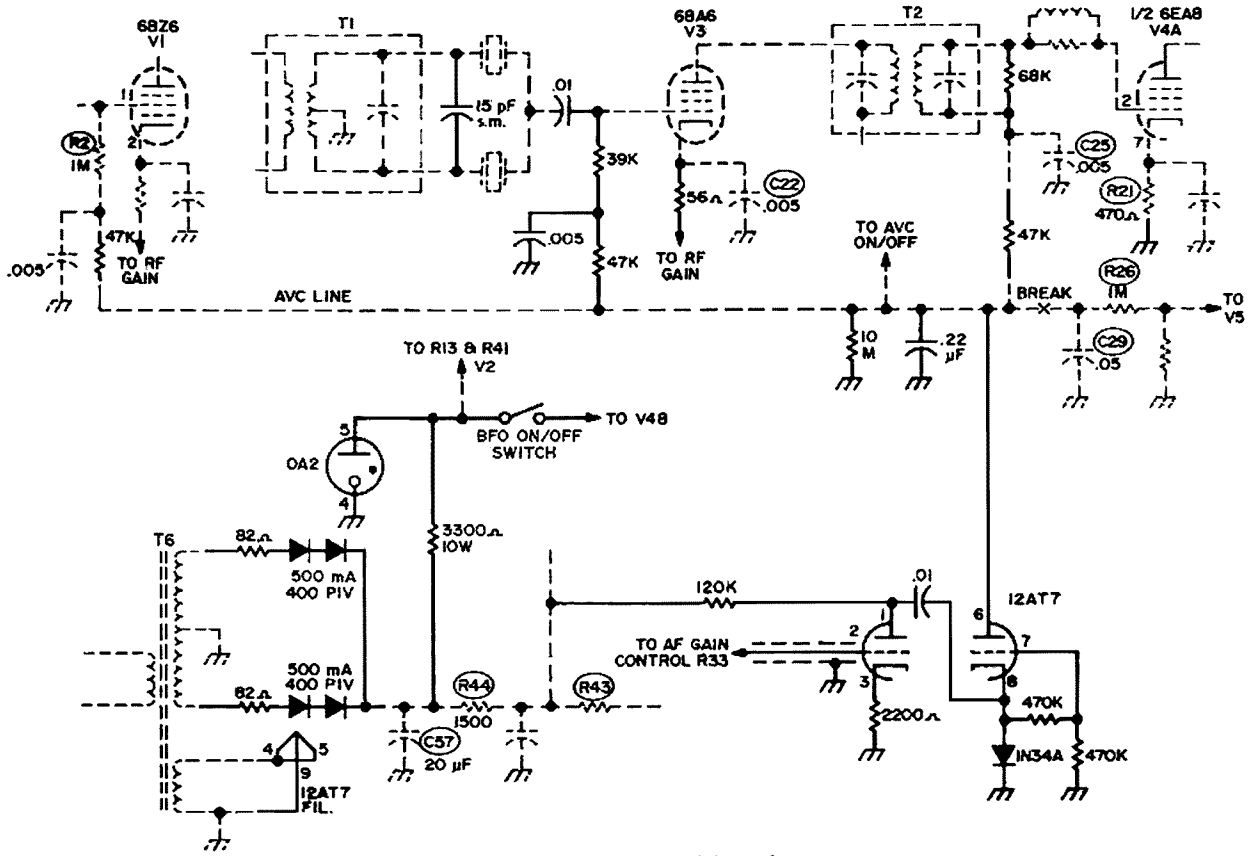
Modifications to the power supply consist of installing silicon diodes in place of the 6X4 rectifier and adding an OA2 regulator tube. Removal of the 6X4 leaves a tube socket for the OA2 and allows addition of the 12AT7 avc amplifier without undue load on the filament transformer. A few directions follow:

1. Remove V7 and unsolder the red transformer leads from pins 1 and 6. The connections to pins 3 and 4 are left in place. Remove the lead to pin 7.

2. Install a terminal strip for the diodes

and 82Ω surge resistors. Complete the OA2 wiring.

3. Clip the two red leads carrying B+ to the junction of R13 and R41 at the single-lug terminal strip near V2. Solder the two red wires together and tape. Route a lead for the regulated voltage along the rear of the chassis and solder to the vacated lug on the terminal strip referred to above.



4. Run regulated voltage to the bfo switch to supply V4B All other stages remain unregulated.

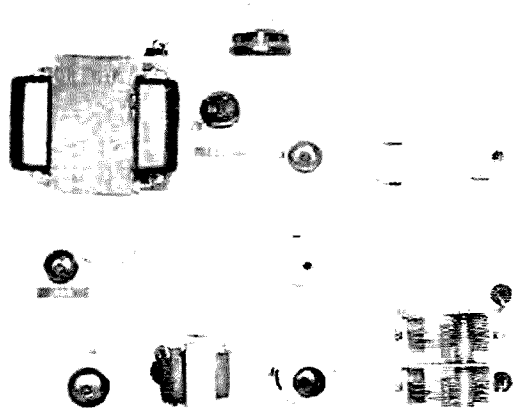
Checks: B+ voltages will read 15 to 20V higher than before modification. A VOM inserted in series with the 3300Ω dropping resistor should read approximately 20 mA for proper regulation.

Audio avc Installation

The existing avc system is discarded except for the avc bus wiring and the avc on-off switch. Notice that the 6BA6 i-f amplifier is modified so that avc can be applied to a third stage. Almost any small-signal diode can be substituted for the 1N34A and either a 12AT7 or 12AU7 will work as an amplifier. Follow the hints below.

1. Remove the fuse block T and install

Schematic showing all wiring changes.



it vertically on the rear chassis apron between the speaker jack and line cord.

2. Install a 9-pin socket between the power transformer and V3. Refer to accompanying photo.

3. Run a shielded lead from the 12AT7 grid to the af gain control. The shield connects to lug 1, the center conductor to lug 3.

4. Ground R21 at V4A. This prevents pinning of the S meter when the rf gain is turned down. Modify the 6BA6 i-f stage. Install 47K resistors in place of R3 and R19.

Checks: With the rf gain fully on, the negative avc voltage should read approximately 1V with no signal and 6–7V on very strong signals. Voltage measurements on the avc line must be made with a VTVM.

I-f Bandpass Changes

Changes to the secondaries of T1 and T2 will alter the i-f bandpass to give a sharper response. T1 and T2 should be retuned slightly after making these modifications. With antenna disconnected and the gains turned up, adjust the slugs for maximum noise while keeping the "hiss" at its lowest pitch. Alternatively, peak T2 as above and then adjust T1 while listening to a weaker SSB signal. Tune for maximum strength and best sounding signal.

I have made these modifications to several HR-10 receivers, and in all cases the owners were well satisfied with the results. Readers might refer to some earlier articles for background information.[1] [2]

10M SOLID STATE

The basic design for this 28 MHz, one watt, solid state transmitter, was developed on 50 MHz. By the time I had it working, the band had gone dead. So I shifted it to 28 MHz. With a few minor changes, it will work on either band, using the same transistors and suitable inductances.

There are three unconventional features about the design, one being the neutralized buffer stage, because on 50 MHz I found it necessary to neutralize *both* buffer and final. The neutralization is not to prevent self-oscillation as one might think. What it does do is to greatly improve the modulation characteristics. On 50 MHz it also cleaned up some TVI that appeared during modulation peaks.

Another unusual feature is the final tank circuit. It is really a pair of tank circuits in parallel. The exact configuration was arrived at by trial and error. However, since any change that I make in it seems to cause the output to drop, the logical thing is to leave it the way it is.

I normally run the transmitter from the cigar lighter in my Volvo. The car battery voltage is 12.4V with a negative ground. At this voltage the final draws .060A for a dc input of 750 mW. The input can be raised to 1W by inserting an extra 1.5V dry cell in series with the 12.4V to the modulation transformer secondary. There is so little difference at the receiving end that I seldom bother to do it.

The audio section is a 12V, 1W commercial amplifier obtained from Radio Shack for $5.95. At that price, it's hardly worth while to build your own. The only trouble with this one – and most low-priced audio amplifiers – is that it has a positive ground. Be careful what you do with the microphone shield ground and the volume control ground. Naturally you will insulate the amplifier printed circuit board from the metal box in which it resides. Don't do what I did, and hard wire the volume control to both the amplifier ground and the aluminum box at the same time. All it did was to wipe out a half-inch section of printed circuit trace leading to the power switch. Fortunately this was easily replaced.

There is always a problem in locating a suitable modulation transformer for the higher powered solid state transmitters. That is the reason for the 1W output transformer wired back to back with the output transformer of the regular amplifier. This system is not 100% efficient, but it does get around the problem. Since we have more audio than we really need, the loss of efficiency is not serious.

The most unique feature is the combination of the diode and audio bypass condenser in series with the buffer collector. This arrangement was evolved in the process of obtaining upward modulation of the output. The result was semi-spectacular. Since there is no splatter and no appreciable distortion at the receiving end, it appears to be a practical approach. The 1K resistor (in the dc path) was chosen in order to provide the

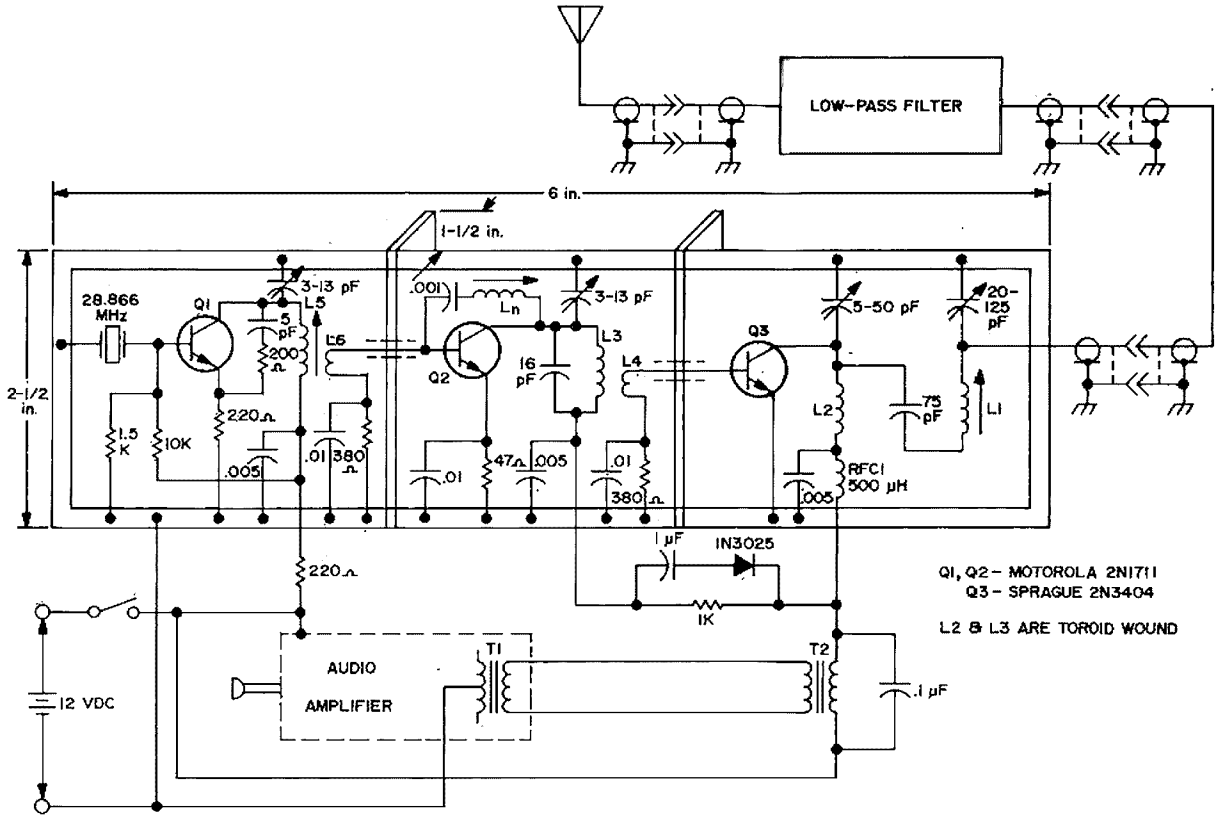

Fig. 1. Schematic of the 28 to 50 MHz rig. Coil data: L1, 3/8 in. dia. 6T #18 ½ in. length; L2, "Red" core toroid, 7T; L3, "Red" core toroid, 8T; L4, 2T wound over L3; (Note: Buy one Amitron package — use the "Red" core for L2 and the "Yellow" core for L3. Use 10T for L3 and 3T for L4. 28 to 30 MHz happens to be the area in the spectrum where the "red" and "yellow" cores overlap.) L5, ¼ in. dia. 10T, #22, ½ in. length; L6, 2T over cold end of L5; L7, ½ in. dia. 24T #24, close spaced (or J. W. Miller #4204 5–12 μH choke); T2, 1W transistor output transformer 150Ω : 8Ω, dc resistance 8Ω pri. : 1Ω sec.

proper amount of drive for the final.

The 2N1711 is a surprise, especially up on 50 MHz. It turns out that only certain brands of 1711's work at the higher frequencies. The Fairchild 2N1711 does not work. Apparently it is manufactured by a different process than the Motorola 2N1711's which I am using. A friend who works at Fairchild refsued to believe this. He took my MOT 2N1711's into the Fairchild lab and verified there was indeed a difference.

If you cannot find MOT 2N1711's, then I recommend the little brother of Sprague 2N3404, which is the 2N3414. It can be used as oscillator and buffer. The RCA 2N3118 will work in the final, but it costs four times as much as the Sprague, and does not work any better.

The low-pass filter is pretty much a requirement. My 5W CB transceiver has one built in. Solid state finals are always rich in harmonic output. Be certain to measure the output power on the downstream side of the filter. Otherwise you won't know whether any improvements you make are increasing the output at the fundamental or merely increasing the harmonic output.

The neutralizing coil for the buffer is rather large at 29 MHz. What is needed is a combination of "C" in picofarads and "L" in microhenries that will equal 30 (for 29 MHz) when multiplied together. My approach is to take a 2 pF fixed capacitor and solder it across the coil. Then adjust the turns on the coil to get a dip at 29 MHz with the slug all the way inserted. That indicates a 15 μH coil (ignoring the distributed capacity of the winding). Of course if you prefer the chicken method, just take a National XR coil form and wind on 24 turns of #24 wire close spaced.

Some type of rf power and VSWR indicator is highly desirable for checking the output and also the modulation. There are two types of these gadgets sold for use in CB rigs for under $10. Either one works fine on

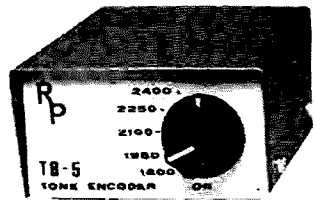
28 or 50 MHz. My rig with 12.4V input will provide 2.2V defection on the 3V scale. If I wanted full scale deflection for VSWR measuring purposes I would simply add a 6V battery in series with the 12.4V car battery (but don't modulate it under these conditions).

It turns out that an NE-49 pilot light soldered across the end of a piece of RG-58 coax makes a fine dummy load and modulation indicator. The VSWR checks out about 1.1 to 1.0. I can light the bulb to full brilliance by blowing in the microphone with only 12.4V dc input.

I am using the Hustler mobile loaded whip antenna mounted on the rear bumper of the Volvo. The VSWR checks 1.3 to 1, which is satisfactory. Solid state final amplifiers do not tolerate high VSWRs. Anything worse than 1.5 to 1 may cause trouble.

Just as I was about to mail this article to 73 I made an important discovery. It came about when I moved the modulation transformer T2 from its original position on top of the chassis to a neater looking spot near the crystal oscillator. Everything fell apart. The output fell way off and the modulator ceased to modulate.

Because I am a ham first and an engineer only from necessity, I stumbled over the answer. The bypass condenser across the secondary of the modulation transformer cured the problem. I first tried a .002 mF bypass which did not seem to help at all. Next I tried the .1 mF capacitor that appears in the schematic and everything worked again. You may not need it. It apparently depends on the placement of parts. On the other hand, it doesn't seem to hurt. In fact, it seemed to help a little over the original configuration.



On the air the expanded positive peak modulation can be mistaken for double sideband with slightly more carrier than normal. The only disadvantage is that some distortion products are perhaps generated which appear on Channel 5 if in close proximity to the TV receiver. The Drake 100W lo-pass filter will take care of this problem if it is bothersome. Naturally, we don't really need a 100W filter, but Drake doesn't build a smaller one.

FREE HANDBOOK

1200 PAGES!

Where else can you get an amateur radio handbook for free? That's right, you get about 1200 pages of articles in 73 every year and the magazine is designed so that each and every article is on separate pages – and 73 is the only magazine that does this – with no flipping to the back of the magazine for a parts list or anything. Every page of the magazine is numbered with the regular numbers plus special yearly handbook page numbers – all so you can, if you like, take apart your issues of 73 and put them together by subject into a giant handbook at the end of the year. No other magazine has anything like this available.

ACTIVE EDITORS

Only one ham magazine of the four has editors that are active and on the air – and have been for years. 73 has its own repeater going – the only ham magazine staff that has done this. 73 has its own mountain top laboratory for VHF – the only ham magazine with one. 73 is active on slow scan television – the only magazine to do this. 73 goes on DXpeditions – the only ham magazine to do this. 73 runs DX tours – the only ham mag to do this. And so it goes.

And what difference does all this make? Perhaps you've noticed that 73 is more involved with the hobby – 73 not only reports the most interesting news, sometimes it helps to make the news. It helps 73 to be more fun to read, to attract better authors for articles, to bring you more valuable information on the newest of ham products.

Which ham magazine was the first to report on the first commercially made two meter synthesizer? 73 of course. And which got the first new units made by Genave? And which got the first Clegg units? The first International Signal units? The first Drake FM units? The first Tempo units? And so on – being active and on the air helps make 73 more interesting and valuable, doesn't it?

73 NEWS PAGES

You'll enjoy the monthly news reports on what is going on in the hobby – new products – political happenings – news of DX – RTTY news – Slow Scan news – VHF news – FCC news, etc. 73 is the ONLY ham magazine to cover the news of amateur radio in this easy to read manner. Keep really up to date with the 73 newspages.

73 MAGAZINE PETERBOROUGH NH 03458

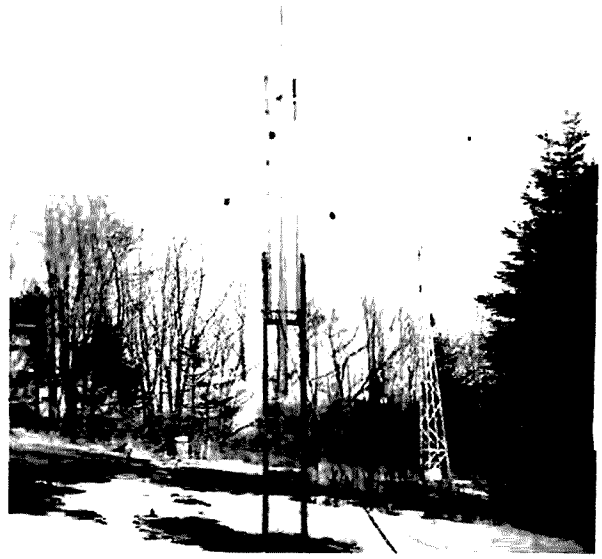
If you prefer not to shred your copy of 73 there is no real reason why you should not put the subscription information on a separate piece of paper, on the margin of a hundred dollar bill, or whatever turns you on.

Regular subscriptions ordinarily start with the next published issue of 73 – the November issue, in this case. Gift subscriptions marked for Christmas will start with the Giant January issue since that is the one that should arrive right around Christmastime. If you want otherwise just indicate same on the order.

The regular subscription rate for 73 is $6 for one year $11 for two years, $15 for three years in North America and $1 extra per year for foreign subscriptions. This special book premium offer is valid world wide at $6 for one year until December 31, 1972.



The recent serious rise in postal rates will be forcing 73 to increase the subscription rate soon – don't say you weren't warned.

Did you enjoy the article in August on the DXpedition to Navassa? This is one of the reasons that 73 is different – it is involved. The editors get out there and operate, go on DXpeditions, organize them even – organize ham tours – set up repeaters – work in the contests – work lots of DX – are actually on slow scan – on RTTY – it makes the magazine come alive. When the editors write about something you know that they have the background to bring you the inside scoop. If you are the type of person who fights progress – opposes change, you are going to find 73 getting your back up, for 73 is in there first with the new things.

A HUSKY 40 M GROUND PLANE

It seems that the middle of the winter is the time I end up building antennas, which may be because of the coincidence of the contest season. However, this was quite a mild winter in these parts, so come February the need for a 40m antenna found another project being conducted between the sporadic snowflakes.

Since I had experience with 40m groundplanes in high-wind areas, it was obvious that such an antenna must be built with an eye to strength as well as performance. It seems most groundplanes are thrown together out of TV tubing or similar material, and the end product seldom lasts long. On 40m the 33 ft of vertical radiator must be well supported.

A little study of Fig. 1 and the photographs will reveal most of the construction features of this antenna. The main support framework is made of well-seasoned 2x4s, with four sections being used to form the legs and a number of short pieces used for spacer blocks. Carriage bolts and lag screws are used in place of nails to prevent premature parting due to wind flexing.

Two short pieces of angle aluminum are also bolted across the frame legs; these are used as the main supports for the radiator. The radiator itself is very sturdy, being made of three sections of aluminum tubing. The bottom section is a 20 ft length of 3 in. irrigation tubing, an item respected for use in yagi beam construction. Besides being very lightweight, this material is able to withstand years of wind and weather stresses.

Telescoped inside the bottom section is a length of 2 in. irrigation tubing. In my case this was a scrap piece from a quad project, but if you have a full 20 ft length available, this would be ideal to complete the overall length of the antenna. In my situation I was forced to go to a third section which is a 10 ft length of thick-wall aluminum conduit such as the type used for house wiring. The three pieces are telescoped inside each other to make up the required 33 ft of overall length, with sufficient overlap to insure strength at the two junction points.

Probably the hardest part of the whole project is to accurately position the pipes inside each other so that the three pieces are concentric, while allowing proper electrical connection between each other. The best way, if a machine shop is available, would be to machine aluminum spacers or collars that would fit inside the larger diameter tubing and have a hole in the center to accommodate the smaller size. However, some study of Fig. 2 will show a

suitable method which will serve the purpose.

Four small blocks of hardwood are used, cut from a single piece of square hardwood molding. The four blocks are wrapped in thick aluminum foil (the kind used to wrap electronic equipment for shipment). The foil usually has a backing of a canvas-like material, and the idea is to wrap the wood so that the foil will make contact with both the outer and inner pipe.

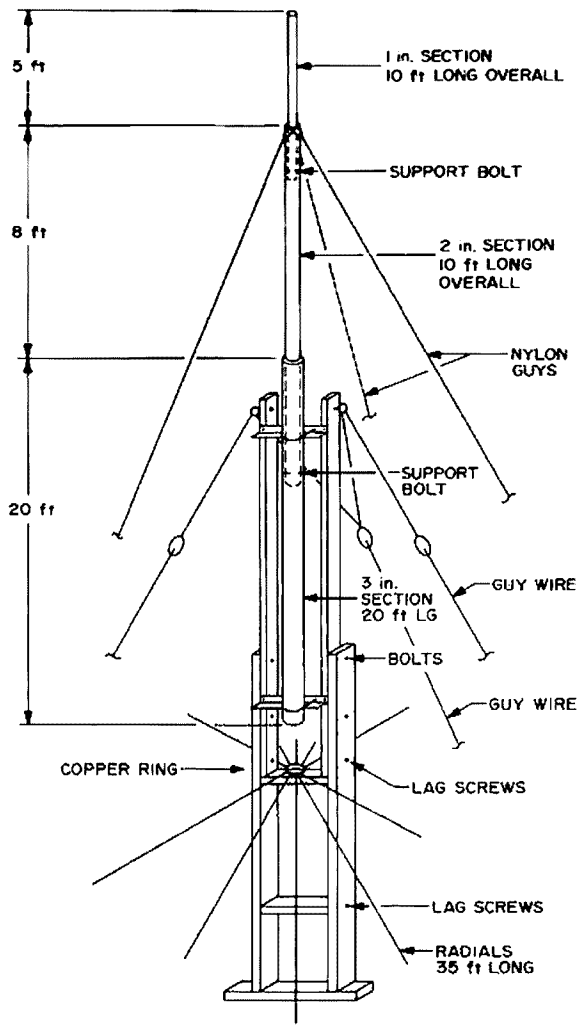

Fig. 1. Details of overall construction.

I held the foil on the wood with a generous dose of glue. Position the four blocks around the inner tubing and use dabs of epoxy to fasten them to the pipe. This is only really necessary on the lower blocks because they will be too far down inside the outer pipe to be reached. The blocks at the upper end of the pipe can be tapped into place at the top of the pipe.

As a means of supporting the pipe at the correct length, two small aluminum bolts are used to hold the inner pipe in position. These are deliberately placed at the lower end of the inner pipe to avoid any mechanical weakness at the junction.

We cannot really depend upon this for good electrical connection, although it will likely be quite sufficient. However, Fig. 3 shows the bridging connection at the junction of the pipes. This is made quite simply by using strips of grounding braid and stainless steel hose clamps.

Fastening the completed radiator in position is the next step. The simplest way is by using two large muffler clamps, well primed with several coats of rust inhibitor. These are ideal for gripping the large tubing firmly and yet not denting it. The clamps are placed around the tubing and mounted onto the two angle aluminum cross pieces on the frame.

At this point, decide upon the distance you want from the ground level to the bottom of the radiator, and then slide the radiator through the clamps until it is in the required position. The distance will depend somewhat on personal preference or availability of space for radials. If you intend to bury the radials, the base can be very close to the ground, but in my case I have the radials above ground and sloping downward at a 10-degree angle. This gives a little better match for RG-8/U cable, and also allows the radials to be rolled up easily when summer lawn mowing becomes necessary.

Before attaching radials, the antenna can be raised into position and guyed. By pegging the base to a short pipe or stake driven into the ground, the antenna can be raised by one man. However, have a helper on hand to tie down the guy wires or disaster may overtake you! Two sets of guys are used. The lower guys are attached to the main frame, and can be your choice of materials. I used heavy aluminum clothesline wire covered with heavy plastic – it's easy to work with and not prone to kinking. A strain insulator in each guy breaks up any possible resonance in the wire.

Mark the positions for the three lower guys, in an equal triangle and about 10 ft out from the base. The stakes should be at

least 4 ft long and driven into the earth to almost their full length. As a suggestion, drill the ends of the stakes and insert a steel U-bolt, which will offer much easier attaching of the guy wires. A steel turnbuckle between this U-bolt and the guy wire will offer precise adjustment of tension on each guy and save a lot of bothersome hit-and-miss tightening later. I have also extended the guy wires from the turnbuckle back to the base of the frame. This prevents any tendency of the base to move sideways under high winds.

The upper set of guys are made from an insulating line (nylon, polypropylene, etc.), but try to use a line with minimum stretch and also one which is impervious to rapid changes in temperature or wetness. Be especially certain it will not rot. If available in your area, it's hard to beat the woven line used for deep-sea fishing nets. This is virtually indestructible and good for years of use.

Fasten the upper set of guys directly to the radiator at the top of the 3 in. pipe. These guys may be fastened to the same stakes as the lower set, but a much stronger arrangement can be had by using another set of stakes some 5–10 ft farther out from the base.

When the antenna is raised and guyed, the radial system can be installed. How many? Simple. The most you can get. More radials mean more efficiency and lower angle of radiation. Of course it's very hard to measure the slight improvement that one more radial makes, but 10 more radials

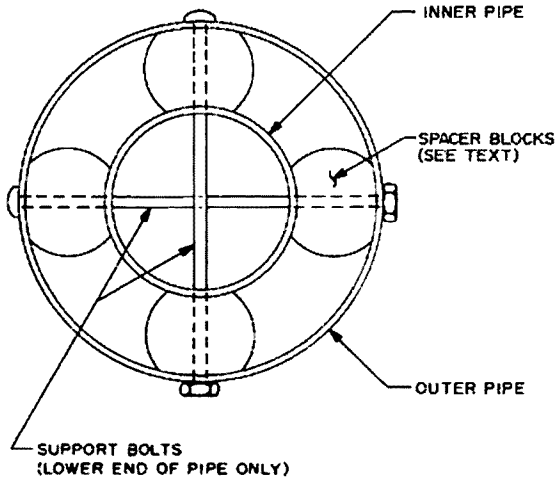

Fig. 2. Details of pipe junctions for tight fit.

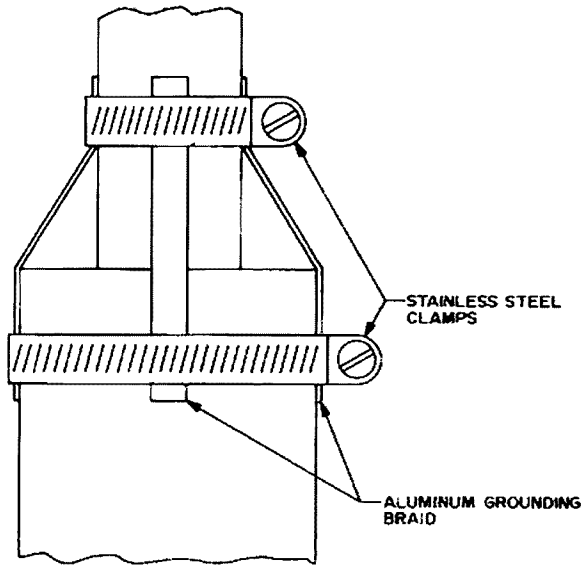

Fig. 3. Method of electrically bridging the junction of the radiator sections.

may get your attention. They can be made from any wire you can get.

The length of the radials should be about 10% longer than the radiator. The ends of the antenna can be all cleaned, soldered together, and then clamped or soldered to a short piece of copper braid which in turn is soldered to the shield of the coax feedline, either directly or via a connector. Although the ideal pattern for the radials would be to space them equally in a circle around the radiator, they can be bent or crammed into whatever odd space is available without seriously lowering the efficiency of the antenna.

Standard 50Ω cable is used to feed the radiator, and direct feed to the base of the element will result in a reasonable swr in the neighborhood of 1:1.5 or a little lower. However, a closer match (and an swr nearer unity) can be achieved by use of a coaxial matching section.

The antenna will perform very well. I believe my best DX (in rarity, not miles) is FB8XX, but the log contains many QSOs with VK, ZL, 9J2, 5H3, 5Z4 and most European countries. The wind loading is slight, and with reasonable attention to painting the frame occasionally and checking the guys, the antenna should give excellent satisfaction for many years.

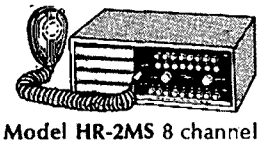
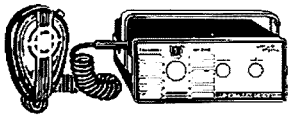
Regency 2 Meter FM—American made at import prices

NEW **Instant access to 144 frequency pairings with 20 watts out on the new HR-212 twelve channel 2 Meter FM Transceiver by Regency**

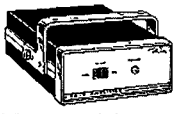


Specifications

Power Output: 20 watts (nom.) at 13.8 V DC
Frequency Range: 144-148 MHz
Channels: 12; crystal controlled
Sensitivity: 0.4 uv, 20 DB quieting
Spurious Rejection: 60 DB



Model HR-212 **$259 Amateur Net**
Includes microphone, mounting bracket and factory installed transmit and receive crystals for 146.94 MHz.



for all your 2 Meter FM needs

Model HR-2MS 8 channel Transcan™ with signal search reception and 15 watts minimum output. **$319.00** Amateur Net

Model HR-2A 6 channel transmit, 12 receive 2 Meter FM Transceiver with 15 watts minimum output. **$229.00** Amateur Net

Model AR-2 Amplifier boosts 2 Meter FM output power 300%.

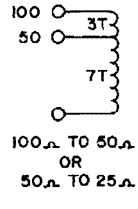
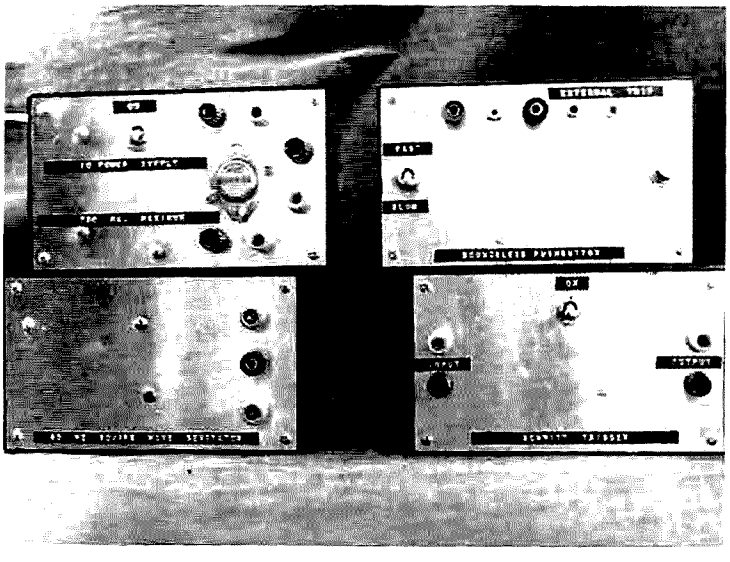
ONE CONVERTER INTO TWO RECEIVERS (such as for VHF contests)



If we assume that your converter output is 50Ω and that the average ten- or twenty-meter receiver you use for a tunable i-f is something like 100Ω input impedance, it would seem that you could parallel two receivers with no trouble. However, you will find trouble with (1) leakage and (2) "sucking out" of the signals by the antenna-tuned circuit of the other receiver.

Padding with resistor networks helps, but the right way is with a "power divider." L is a centertapped coil. I twisted a pair of #30 Formvar wires together and wound five bifilar turns through a ferrite bead of the kind we used to use for heater decoupling – 3/16 in. diameter by 3/16 in.

long x 1/16 in. hole. Pick the proper ends to hook together, and we have 10 turn, centertapped coil. The two outputs are 100Ω each. Ten turns tapped at seven on



one of the same beads will make you a 100:50Ω auto transformer, if you think it will help.

IC LOGIC DOESN'T HAVE TO BE OBSCURE

With 40 meters a mass of heterodynes and 15 meters sporadic my two Novices had some time on their hands. Putting aside a study of the latest schematic diagram in the Playboy centerfold, I unveiled my latest bargain buy, a gaggle of J-K flip-flops and dual two-input gates. With an introduction to the world of IC's via the verbal route, it soon became apparent that some sort of dynamic demonstrator was needed. Several days of drawing schematics, hacking up perf board and constant construction produced a number of units which brought reality to the fundamentals of "counting with educated stones."

The first unit was a power supply. Since all the IC's were RTL, the supply voltage ballpark figure was 4V no-load running down to 3.6V when loaded to about 700 mils. Just a word about the power transistor in the regulated supply – while I used an available unit on hand, there is nothing magic about the number. Almost any decent

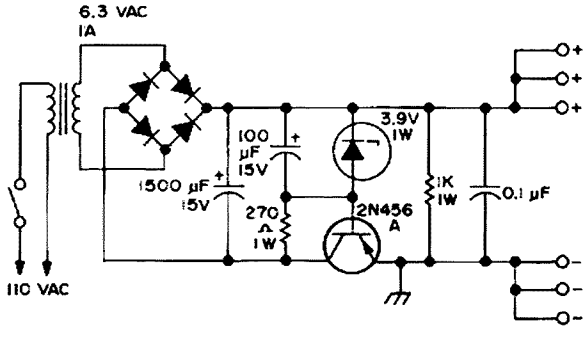

Fig. 1. Power supply for IC demonstration projects.

power transistor will work. By changing the base resistor a bit, up or down, depending on the zener you have on hand, the power supply should present no problem. I used

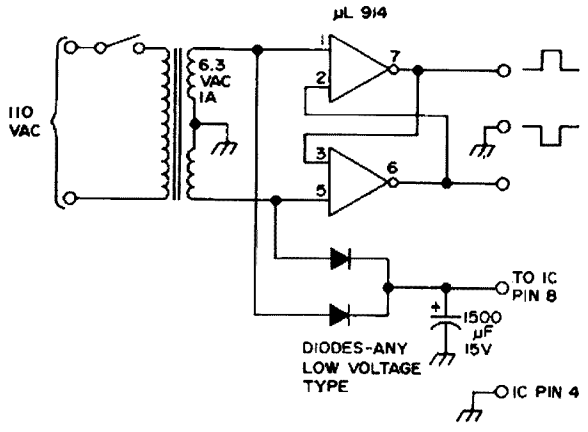

Fig. 2. 60 Hz square waver.

standard 5-way binding posts on all units.

The second unit constructed was the 60 Hz square waver. This essentially is an R-S flip-flop using a dual two-input gate, which is triggered by the 60 Hz from the filament transformer.

This unit was handy as its known frequency square wave was used in demonstrations of methods of frequency counting via oscilloscope patterns when the logic counting board was to be used.

The third unit was a Schmitt trigger

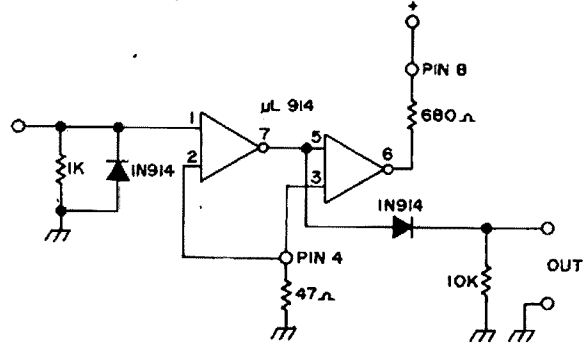

Fig. 3. Schmitt trigger.

which will produce relatively decent square waves from any audio source of 3V or more. It uses another dual two-input gate. Two C cells power this unit. As the current drain is well in excess of what would allow normal shelf-life of the cells, an on-off switch is part of this unit.

The fourth unit was a bounceless pushbutton. This is a device using another dual two-input gate which gives you one – and only one – output pulse when a pushbutton is pushed. I have incorporated two different pulse lengths selected by a toggle switch. The long duration pulse (about one second)

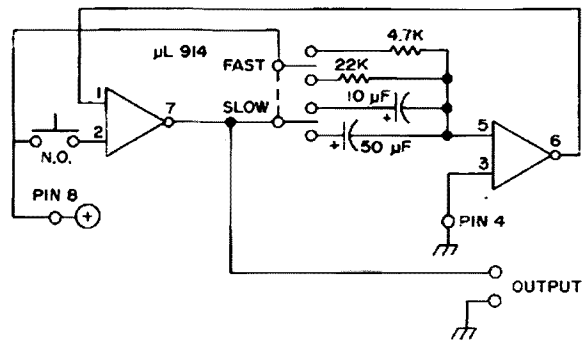

Fig. 4. Bounceless pushbutton.

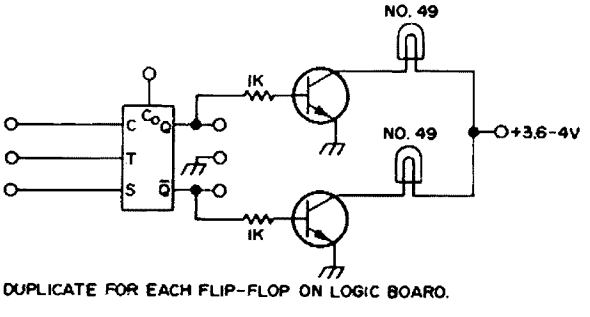
is very useful as it allows you to put a meter from the output terminal to ground and see very graphically how when the button is pushed, the output voltage drops to ground, stays there for the designated interval and then snaps back to its initital value. The current drain of this unit is very low so no battery switch was incorporated and the two C cells will give long service. All four units described so far were built into small plastic boxes with metal panels, readily available from such outlets as Lafayette or Radio Shack.

The final unit, the logic board, was built on a 10 by 10 in. piece of Masonite. The perf board carrying the semiconductors is mounted underneath this panel. Essentially the logic board consists of four RTL J-K flip-flops. Each output of each flip-flop has a lamp driving transistor to show the state of each output. The NPN lamp drivers can be any small transistor with a gain of fifty or more. The base resistor serves to limit the loading on the flip-flop and also control the current through the lamps so they are not overvolted. The No. 49 pilot lamps were friction-fitted into 3/8 in. holes in the Masonite panel and connection to them made by soldering directly to the base. Note



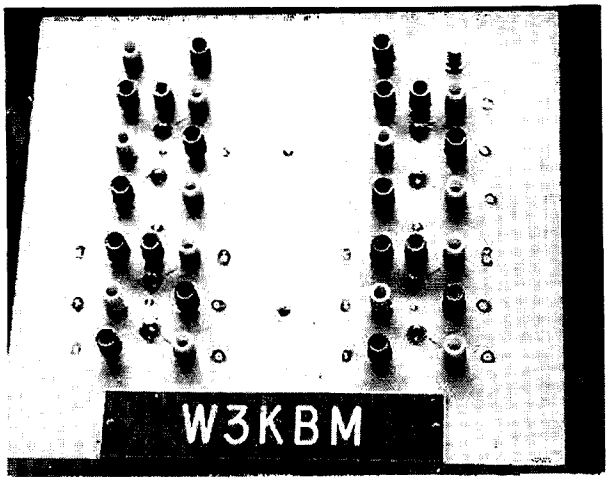


Fig. 5. Sample logic board flip-flop with pilot light display. Author's model included four of these.

Top view of logic board. Reset button at top right.

that each IC has a panel binding post for each input and output for a total of six per IC. In addition a ground binding post is included in each IC binding post cluster.

The only other item on the logic board is a "reset" button. This normally gives a ground when connected to the Preclear inputs. When pushed, however, it gives a momentary connection to Plus which serves to restore the flip-flop to its normal state.

A patch cord system like this is very flexible but demands many connecting cords. I made up multiple connecting cords for the ground system of each IC using spade lugs – three wires in multiple to one spade lug and the other end of each wire having its own spade lug. A similar harness was made up for the "reset" button but this included four wires so all flip-flops could be reset at once if the occasion demanded.

With the simple units described here you can demonstrate binary counting up to number 16 or by alternate connection of the flip-flops, divide by any other number. The bounceless pushbutton is particularly valuable in this use because as you step the counter pulse by pulse, you can make up truth tables based on what the lights show. Naturally if the input is derived from the 60 Hz square waver or the Schmitt trigger, the

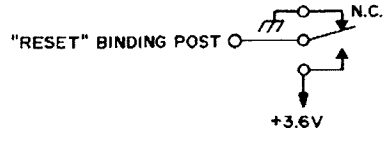

Fig. 6. Reset button detail.

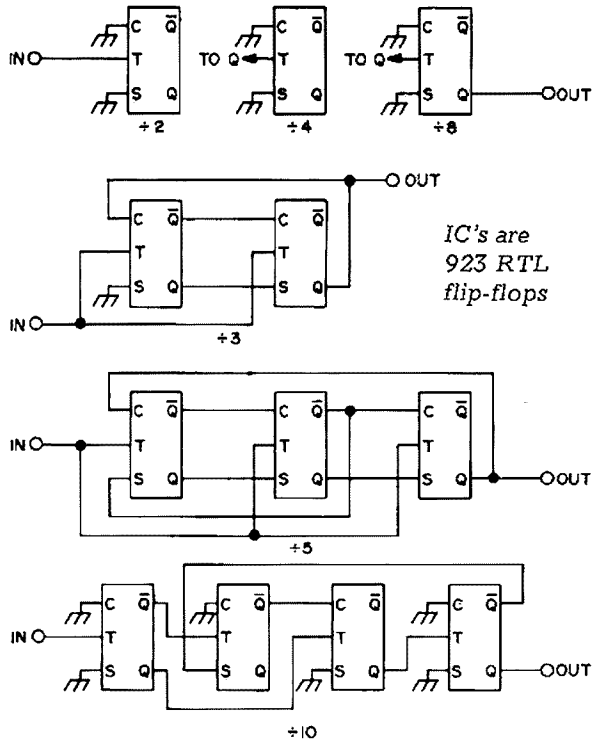

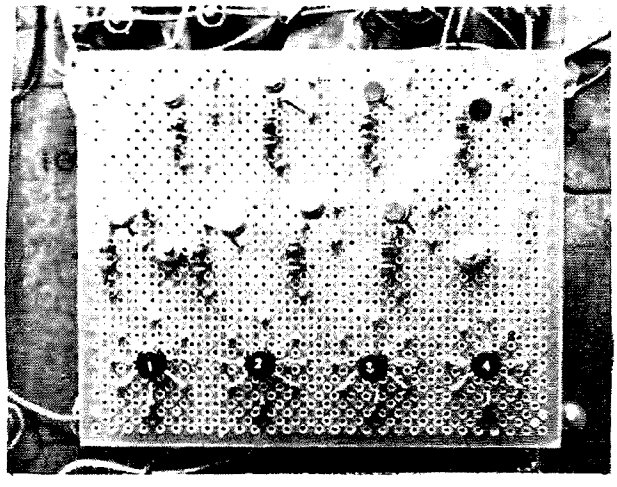

Fig. 7. Logic board sub-assembly

lights in each counting stage will flash at varying rates dependent on the division ratio involved. If the count is much above 140 Hz the bulbs will not blink but will give a steady light due to the persistence of vision and thermal capacity effects of the lamp filaments.

Underside of logic sub-assembly. Black TO-5 cases are RTL flip-flops. Others are lamp drivers.

This little logic demonstrator has really brought the world of IC's alive for my crew. The only tough part is getting the "toy" away from the younger harmonics so it can be used for "serious" teaching.

PROTECT THOSE DIODES

In designing the high voltage supply for high power equipment, many amateurs are turning to silicon diodes, and rightly so, because of their low internal voltage drop, filamentless operation, and reliability. Reliability, that is, if their maximum ratings are not exceeded. In order to rectify a high ac voltage, it is often necessary to use several diodes in series. However, a problem rears its three ugly heads in the form of Peak Inverse Voltage, creating headaches both in the cranium and billfold departments.

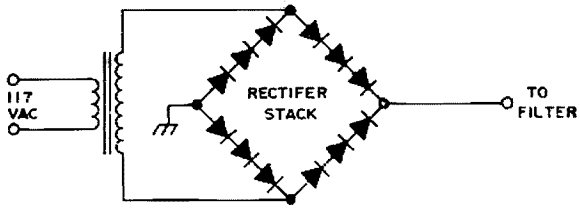

Fig. 1. Standard bridge rectifier using series silicon diodes.

Take Fig. 1, a typical bridge rectified unit. As the primary of the transformer is opened and closed, a high voltage transient appears across the secondary due to a change in core flux. The transient may exceed the PIV rating of the diodes, causing one or more to 'Go West,' and taking the rest of the string along because of a high distributed inverse voltage across them.

The second ugly head is the different characteristics of diodes of the same style. Their maximum PIV may be close, but not the same. These differences may cause the designed PIV to exceed the actual diode PIV rating. The result – abject failure.

The third ugly head arises in the multiple series diode rectifier legs. As the state of the diodes changes from non-conducting to conducting, an indefinite period of time (charge recovery time) occurs. If one diode in the string has a longer recovery time than the rest, it forces the other diodes to carry the extra PIV load until the diode recovers. This additional distributed voltage may be enough to cause one or more diodes to fail, again taking the entire string with it.

As in Fig. 2, the problems can be solved. The transient across the secondary can be eliminated by placing C1, a .005 mF disc, across the entire winding. The capacitor presents a low impedance to the transient, shunting it around the rectifier stack. The voltage rating of C1 should be greater than the peak secondary voltage. (A 5 kV unit will do for a 2000V secondary.) The extra distributed PIV is also easily eliminated. All that is necessary is to distribute the inverse voltage drop across *each* diode by shunting each diode with a .002 mF disc (1200V rating in this case). During the recovery time, capacitors C2–C13 present a low impedance shunt for the inverse voltage around the rectifiers. They also compensate for the different characteristics of the diodes.

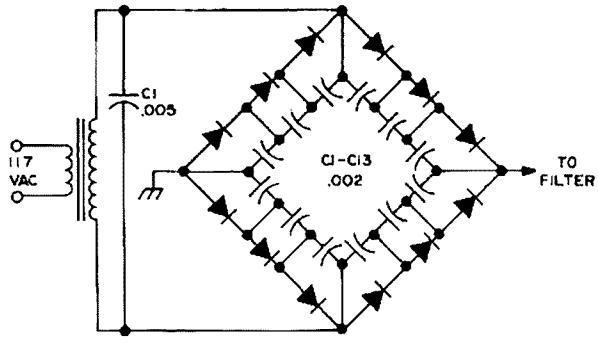

Fig. 2. Capacitor protection from transients across series diodes.

Try these hints and see if they relieve the headaches (especially those in the wallet) and improve the reliability of your operation.

SOLID-STATE OVERLOAD PROTECTION

There are two basic reasons for overload protection in your transmitter or linear. The first is a desire to protect the final tubes from the ravages of excess current. The second and equally important reason is to protect the power supply. While the transformer is often overlooked, it too requires care if it is to survive. In commercial and homebrew equipment careful calculations have been made to extract the last possible watt from a given transformer, the duty cycle has been figured to a fraction of a percent, and if ratings are exceeded there may well be dire consequences in the form of overheating and eventual failure.

Overload protection may be gained in any of several ways. The most common and least expensive over the short haul is a common fuse in the primary and/or secondary of the high voltage transformer. If a high current fuse is used, protection is sacrificed while a fuse near the normal current consumption of the equipment will give rise to frequent fuse changes due to the peaks found in all sideband equipment. Another common form of overload protection is a relay in series with the plate circuit. Excess current will pull the relay in, after which time a holding contact on the same relay will keep the contacts open until reset. The major drawbacks of this system are the lack of precise and lasting adjustment and the usual buzzing of the relay as pull-in current is approached. Presented here is another method which is silent, fully adjustable, reliable, and best of all, inexpensive.

A low value resistor (R1) has been inserted in the negative lead of the power supply. All current flowing from the supply must flow through this resistor and as it does it creates a voltage which is a reflection of the current flow. In parallel with this resistor is a potentiometer (R2) which allows the selection of any desired percentage of the voltage so developed. The slider of the pot is connected to a zener diode (D1) which blocks the flow of current until the applied voltage exceeds the zener point of the diode. The instant the zener voltage is exceeded, current flows through limiting resistor (R3) and the gate circuit of the SCR. The current flow locks the SCR into conduction, a condition which will remain until the anode/cathode circuit is broken or the supply voltage is removed. The overload relay coil is wired in parallel with the SCR. When the SCR conducts, the coil is effectively shorted and its contacts open. This in turn opens the coil circuit of the high voltage control relay and turns off the high voltage.

The high voltage on/off switch wiring is reduced to a single low voltage wire running from the power supply to a convenient location on the main chassis. The same line is also used for reset purposes, thus eliminating complicated switching and cabling. The reset function consists of turning off the high voltage switch momentarily. This removes the voltage from the SCR and allows the overload relay to operate when voltage is again applied. Both pull-in and reset are accomplished in a matter of microseconds. If the condition

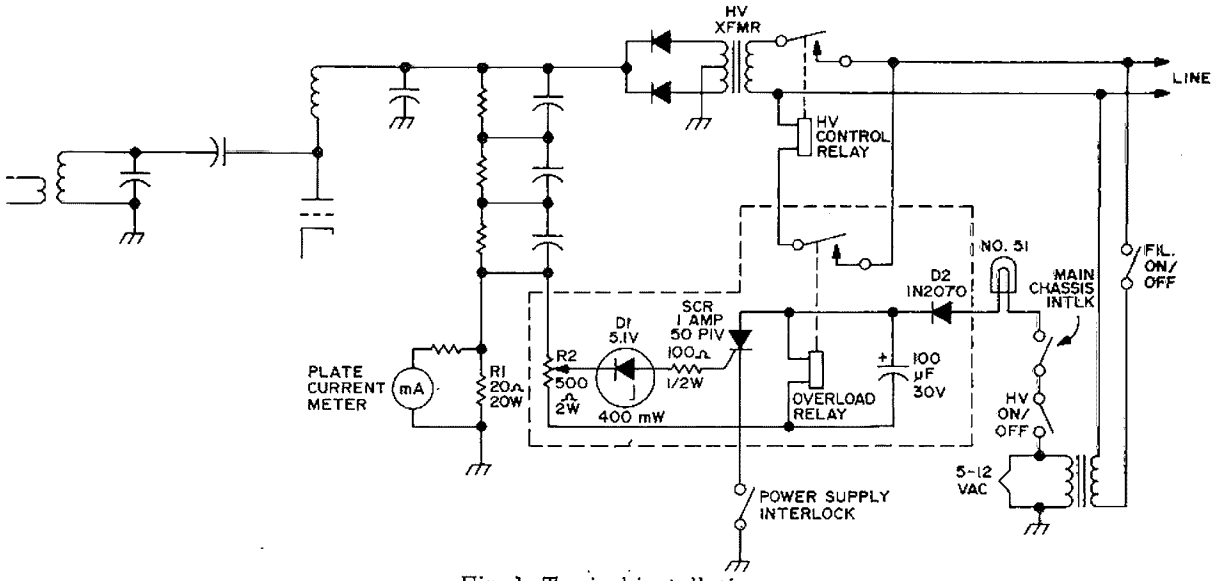

Fig. 1. Typical installation.

originally causing the high current remains, it will be impossible to reset the overload, or rather it will reset only long enough for the SCR to conduct again. The circuitry is also such that it is impossible to apply high voltage without the filaments/heaters having been turned on first. Interlock switches are provided for both the power supply and main chassis. It will be noted that these are required to carry only low dc voltage.

As yet nothing has been said about the pilot lamp in series with the control voltage. This bulb serves several purposes – the first is to limit the current drawn from the control voltage source. The source is effectively shorted in the "tripped" condition without it. The second function is to indicate the presence of power to the high voltage control circuit by a dim glow and of a "tripped" condition by lighting to full brilliance.

The relay used here was intended for 12V dc service. It will, however, actuate at around 5V allowing completely normal operation with heater supplies of 5 to 12 ac volts. This relay is similar to those found in Radiosondes and several types of surplus. The original was purchased for $1.50 from a local surplus house. The exact nature of the relay is not critical.

In equipment having one side of the filament of heating winding grounded, that source may be used for the control voltage. When the winding is above ground a small filament transformer must be added for this purpose.

The circuit as described is capable of adjustment from 150 mA to well over one ampere. Increased sensitivity may be accomplished by installing a lower voltage zener diode or the current sensing resistor may be increased in value.

The parts are inexpensive, readily available, and not at all critical. The original cost $3.18. It was mounted on a PC board measuring 2 x 2¼ in. This is definitely not a requirement, and in fact is not even desirable in view of the extreme simplicity of the circuit and the "one of a kind" nature of the project.

Calibration is very straightforward. First disconnect the high voltage transformer primary from the power line as a safety measure. A source of low voltage dc (battery charger or bench supply) is connected in series with the current sensing resistor and an ammeter. Adjust the current to the desired trip point by adjusting the applied voltage or the resistance in series with the circuit. Advance the sensitivity control slowly until the overload relay drops out. Decrease the current to slightly below the trip point and reset the overload. Again increase the current to verify the setting and make any necessary final adjustment. Remove the test setup and reconnect the power transformer.

If a low voltage relay with larger contacts were available it would be possible to use the overload relay to directly control the transformer primary . . . for financial reasons this was not done. . . .WAØABI

Lab type IF/RF SWEEP GENERATOR using IC'S

Just about every kit-type sweep generator on the market starts life out at around 3 or 4 MHz and ends up at 200 MHz or so. This always made analysis or display of 456 kHz i-f amplifier response characteristics a tedious step-by-step plotting procedure or required time out to rig up a temporary gimmick to do the job. No more. The sweep generator to be described here will do the job with ease and precision. Even if you do not intend to duplicate the instrument, you may find parts of it useful for other applications.

The generator covers a frequency range of from 400 kHz to 30 MHz in five bands. It can be operated in the CW mode as well as swept, thus allowing it to be used as an ordinary signal generator. Maximum output is 350 mV p-p across 50Ω. When sweeping, the return trace may be blanked or not, as desired. Two calibrated dials are provided for setting the start and stop frequencies and the maximum sweep width would be the entire band in use. The frequencies covered by the five bands are: 400 to 900 kHz, 850 kHz to 2.3 MHz, 2 to 6 MHz, 5 to 15 MHz and 10 to 30 MHz. Sweep time is variable between 20 ms and 6 seconds per sweep. A step attenuator in conjection with a vernier control provide a maximum attenuation of the output of 120 dB. An input is provided for a post-injection marker system built into the unit. A synchronous ramp with gain control is provided for driving the oscilloscope horizontal sweep. Blanking pulses are also brought out to a connector in case they are needed for synchronizing external equipment.

A New IC

The heart of the generator is a new Motorola IC, the MC1648 emitter-coupled oscillator. It was intended for use in phase-locked loop systems operating in excess of 150 MHz, but may be used in many other applications such as this one. The device provides output of high spectral purity and incorporates an internal agc system which simplifies design of the sweep generator by eliminating the need for external leveling. A buffer amplifier and emitter-follower output are also incorporated on the chip, eliminating the need for external amplifiers. Figure 1 is a schematic of the MC1648 IC. Figure 2 illustrates two methods for tuning the oscillator. The device is packaged in a 14-pin DIP and requires a 5V dc supply. Since it was

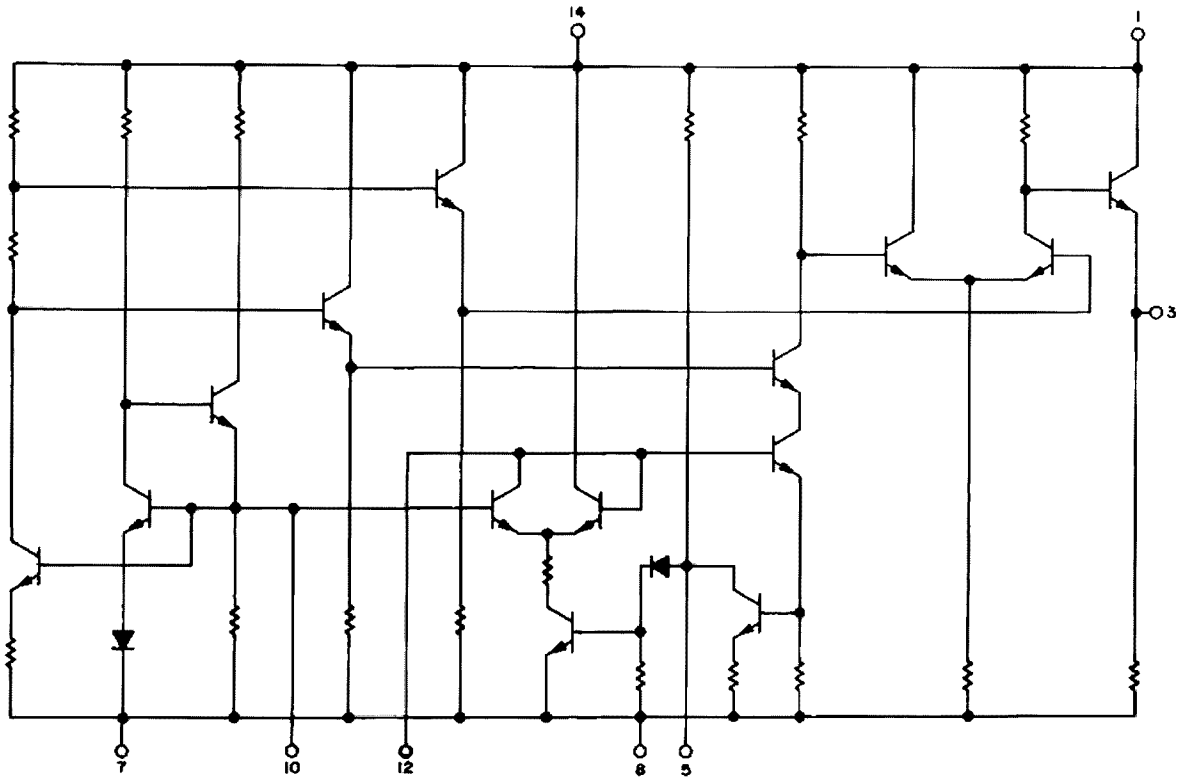

Fig. 1. Schematic of the MC1648 IC.

intended to be used with Motorola MECL III logic, either polarity is permissible. A positive supply is used here, connected to pins 1 and 14 with 7 and 8 grounded.

All the information covered by the data sheet for the MC1648 dealt with operation from 10 MHz up to about 180 MHz. Since I was interested in going as low as 400 kHz, I had to do some experimenting with tank circuits. My best results were obtained with the use of cup cores for the two lowest bands. I also found that ordinary molded iron core rf chokes of the miniature variety did an excellent job the rest of the way. Use of these tiny components made possible a very compact 5-band assembly.

The VCO

In order to facilitate shielding and simplify construction, electronic band switching is employed. Figure 3 is the schematic for the rf portion of the generator. The 2N4391 J-FET has a low 'on' resistance and works very well as a switch. One of these transistors is placed in series with each tank circuit

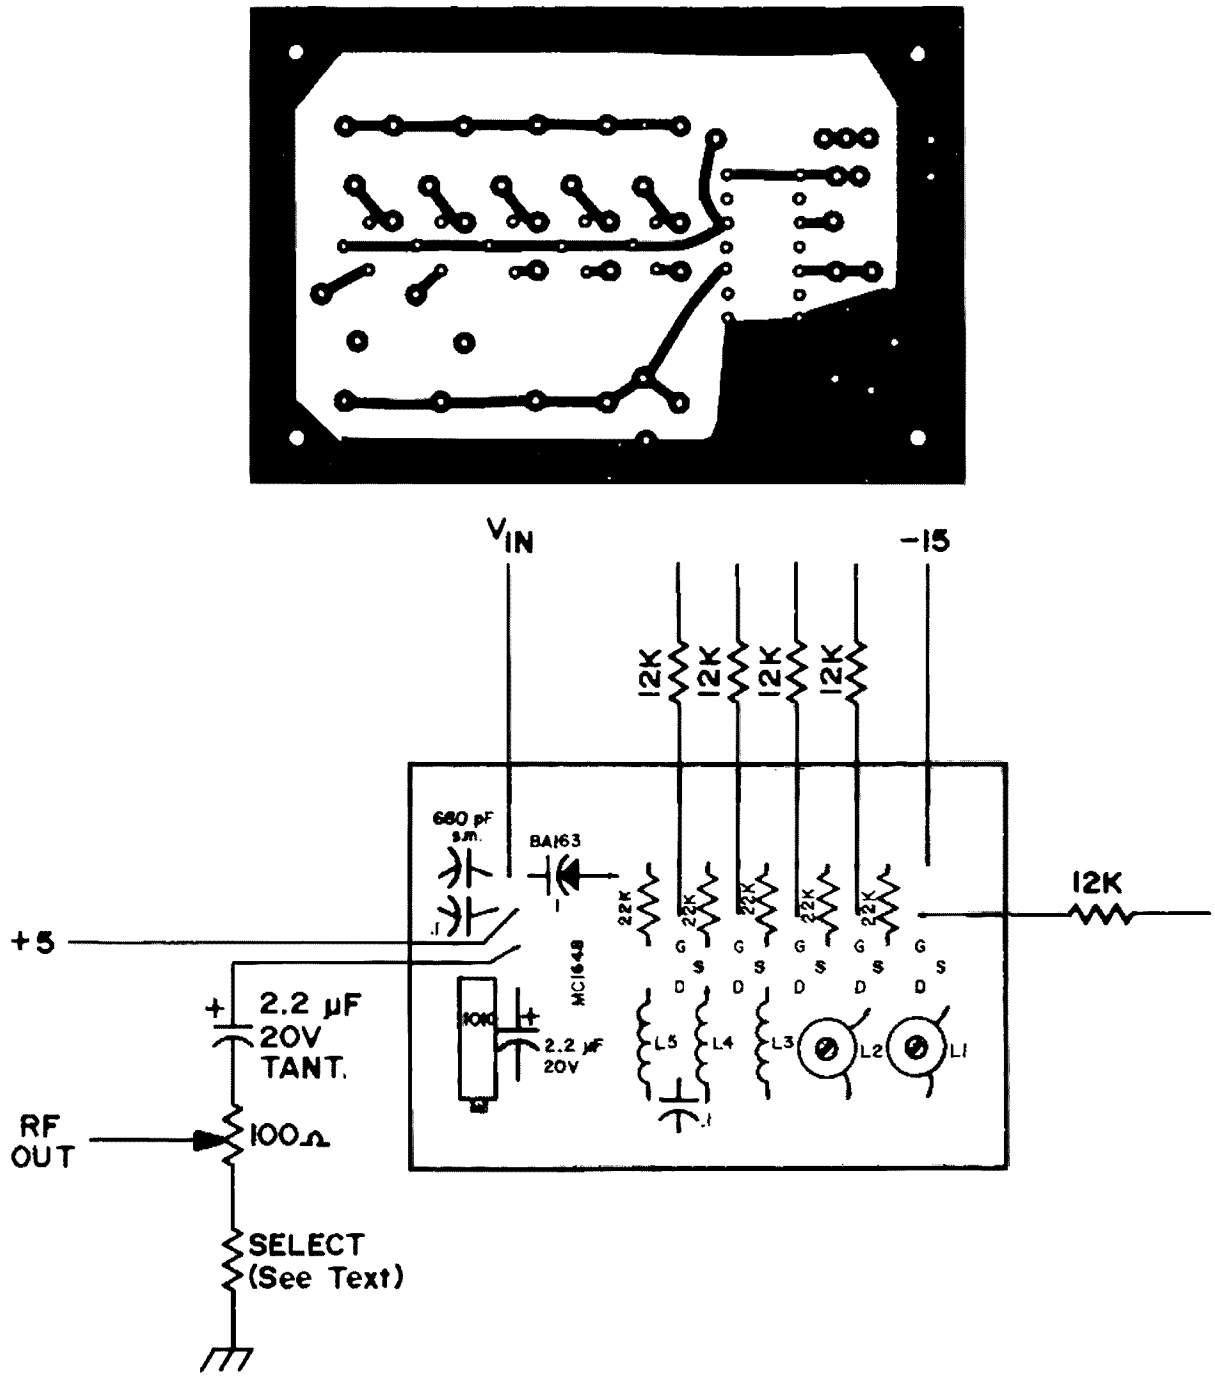
Fig. 3. Schematic of the rf assembly using dc band switching.



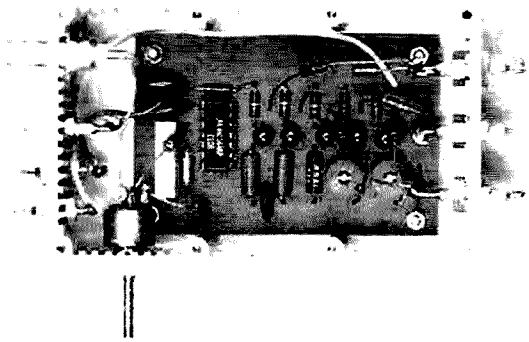


Fig. 4. (A) Foil side of rf pc board. (B) Location of parts on component side.

Completed rf assembly ready for mounting in the cabinet. A plastic version of the 2N4391 was used with a considerable savings in parts cost.

and can be turned on by application of a positive voltage at the gate. This allows the use of a strictly dc-operated remote switching arrangement. The entire assembly is built on a 2 x 3 in. pc board and mounted in a Pomona Model 3306 enclosure with a Model 3328 bottom mounting plate.

A BA163 tuning diode by ITT is used to sweep the oscillator. Although it is intended for bc band use, it performs admirably at these higher frequencies and its high capacitance ratio allows wide sweep excursions. If

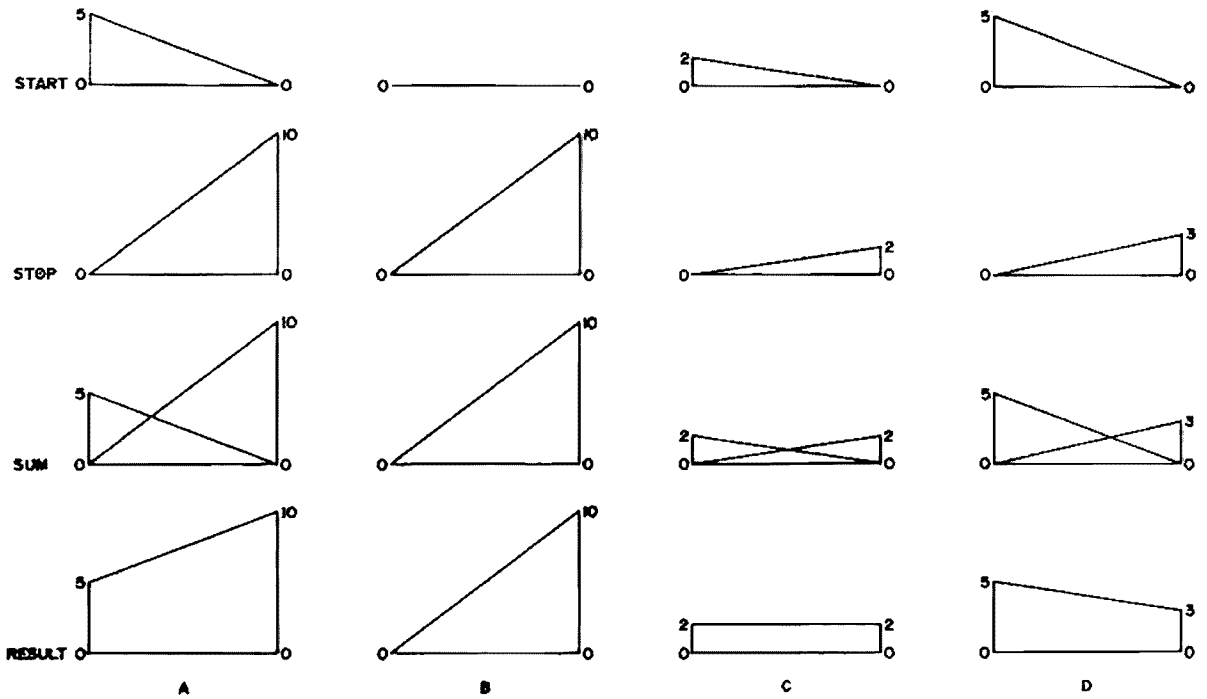

Fig. 5. Pictorial demonstration of ramp generation.

you are planning to use this oscillator for VHF applications, a more suitable diode would be in order. According to the data sheet on the MC1648, typical maximum output frequency is 225 MHz.

The vernier attenautor is a 100Ω RV6 style potentiometer mounted inside the enclosure. A coupling and extension shaft are used to bring the control out to the front panel. The value of the resistor at the bottom end of the pot will have to be selected so that a range of 20 dB is provided with full swing of the control. Since end resistance varies from one control to another, an exact value will have to be arrived at experimentally.

The output from the VCO is a square wave. If sine wave output is desired, the age characteristic may be modified by introducing resistance between pin 5 and ground. The small trimmer incorporated on the board is used for this purpose. It was my experience, however, that this may introduce instability with some MC1648s. Although the trimmer was left in, the one in my unit is turned to maximum resistance where it has no effect and left there. It would do no harm to leave it out altogether since no other changes would be needed.

If any readers are contemplating exact duplication of this generator, you will find the cup cores I used are no longer available. These were Ferrox-cube part number 332P133B4-3C and are obsolete. I had a large number of these on hand left over from another project and saw no sense in buying more. I am sure some of the presently available cup cores will make excellent substitutes. Those used here are about 3/8 in. in diameter and are ungapped. You may have to experiment with the number of turns in the coil to obtain the coverage you require. One handy trick you can pull with a cup core is to rotate the slots in each half so that fractional turns are produced when the coil wires are brought out separately through the two spaced holes. Exerting pressure on the core by means of the mounting screw will also shift the frequency and is almost like having a slug to tune. Increasing pressure seems to raise the frequency. The rf chokes used for the higher bands may also vary slightly from piece to piece and several may have to be tried to get the desired coverage. There isn't much we can do to alter the frequency where the chokes are used. Of course, slug-tuned coils may be used if the pc layout is modified. I do not recommend

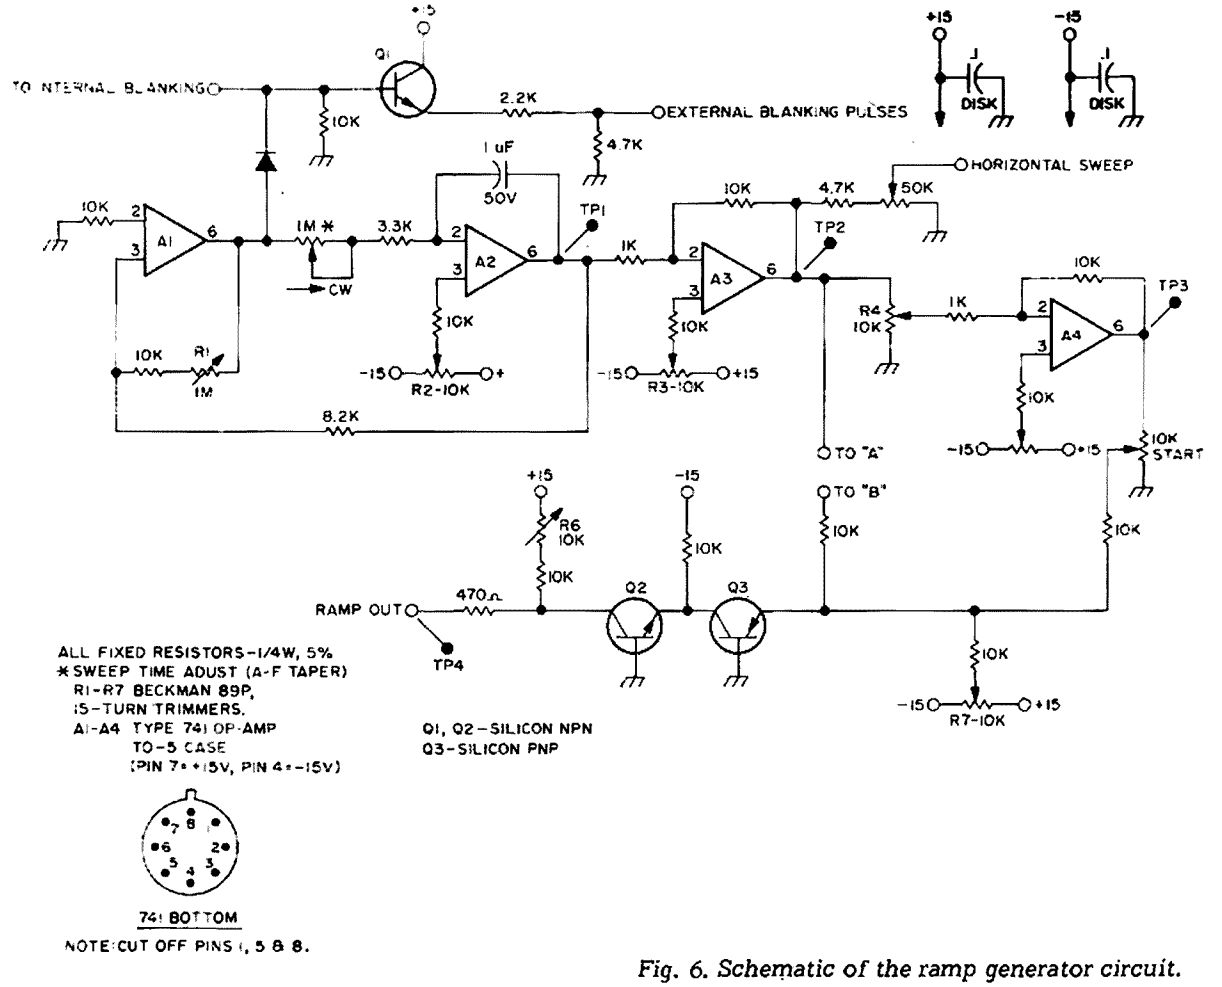
their use on the two lowest bands, however, since my results were rather unsatisfactory with this sort of tank circuit.

One final point would be in order before leaving the VCO. Note that the 10 KΩ resistor going to the tuning diode, the 2.2 μF rf output capacitor and each of the 12 KΩ resistors going to the transistor gates are not mounted on the board. One end of each has a hole provided on the board and then the component itself is used to make the connection to its final destination. This saves board space and eliminates separate wires. The small resistor at the bottom of the vernier attenuator is similarly mounted between the board and the bottom lug on the control. These points are more clearly seen in the photo. Also note that the cup cores are fastened directly to the board by means of 1-72 screws into threaded holes.

The Ramp Generator

In contrast with kit-type sweep generators that use the 60 Hz line for sweeping the oscillator, laboratory instruments have internal circuitry designed for this purpose. In our case, as with most sweep generators, a voltage ramp is used to control the oscillator during the sweep period. The circuitry has been arranged so that we can adjust the starting point (dc level) of the ramp independently of the stopping point. This simply means that we can set the frequency at which the sweep starts as well as the frequency at which it stops. We can also control, over a fairly wide range, the time it takes for a complete sweep. In this case, the sweep time is continuously adjustable between 20 ms and 6 seconds per sweep.

To get a better idea of how the ramp generator produces the results we've described above, let's look at Fig. 4. Note that a negative-going linear ramp (start) is combined with a positive-going linear ramp (stop) to produce the resultant ramp being applied to the varactor diode. If either input ramp is zero, the resultant will be the same as the single ramp since adding zero to anything will not change its value. Naturally, if both are zero, the output will be zero and



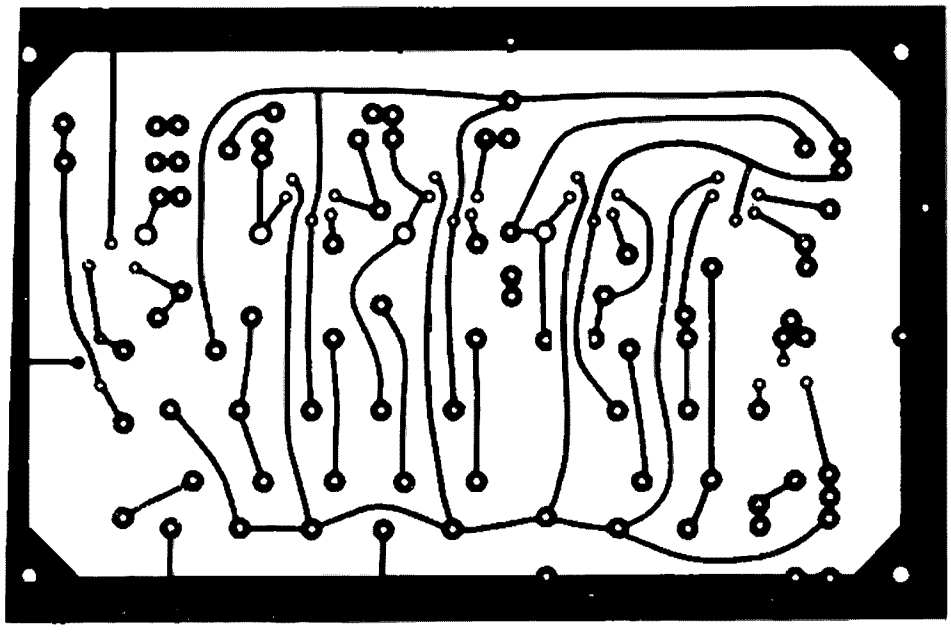


Fig. 6. Schematic of the ramp generator circuit.

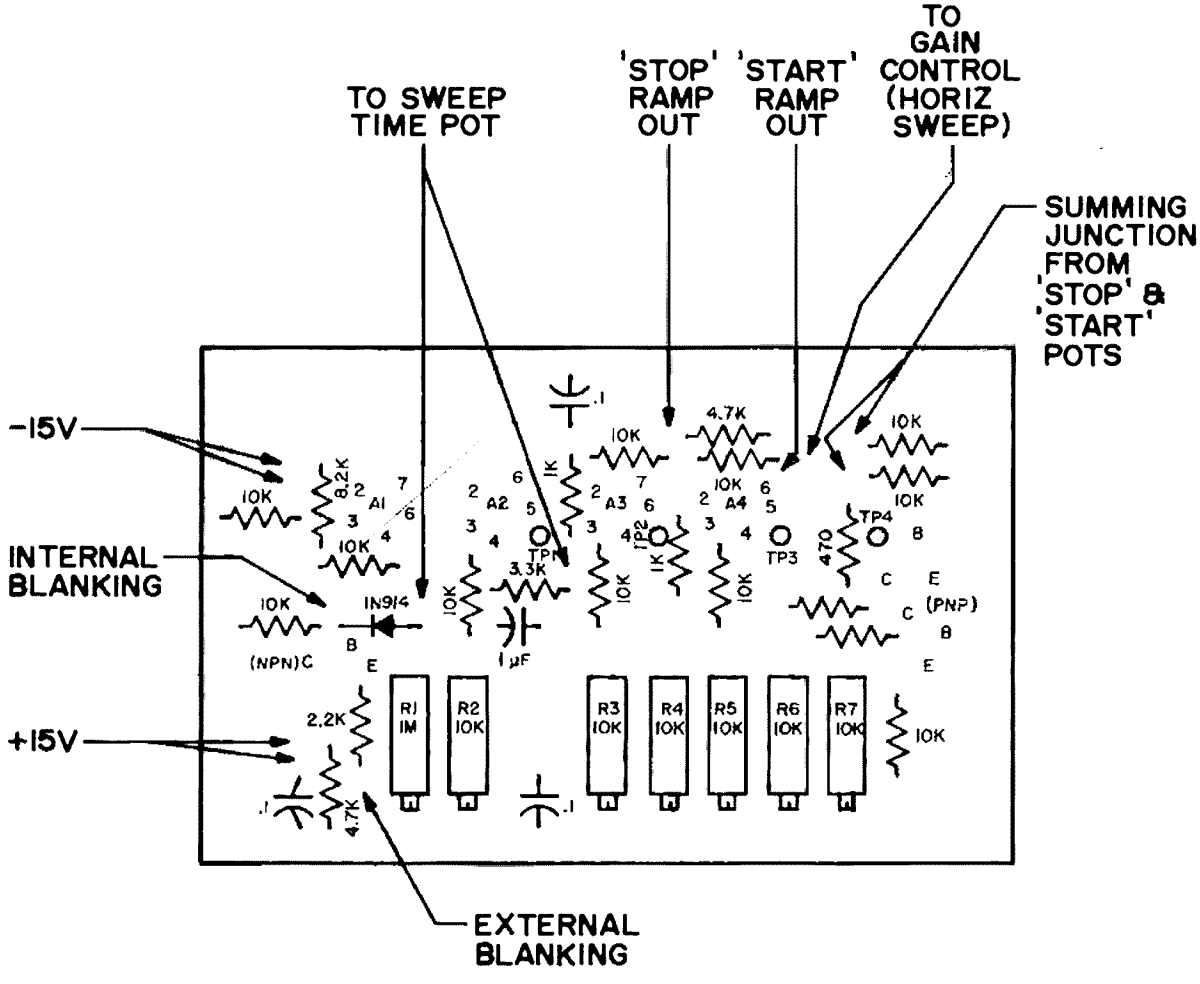

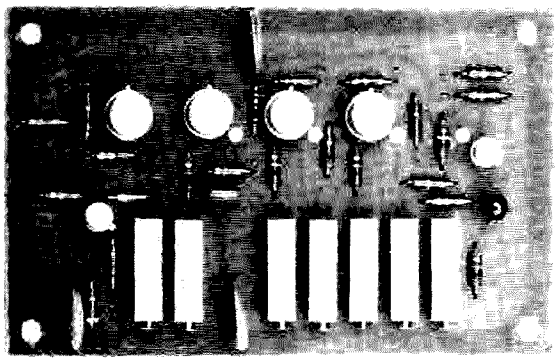

Fig. 7 (A) Foil side of ramp generator board. (B) location of parts on component side.

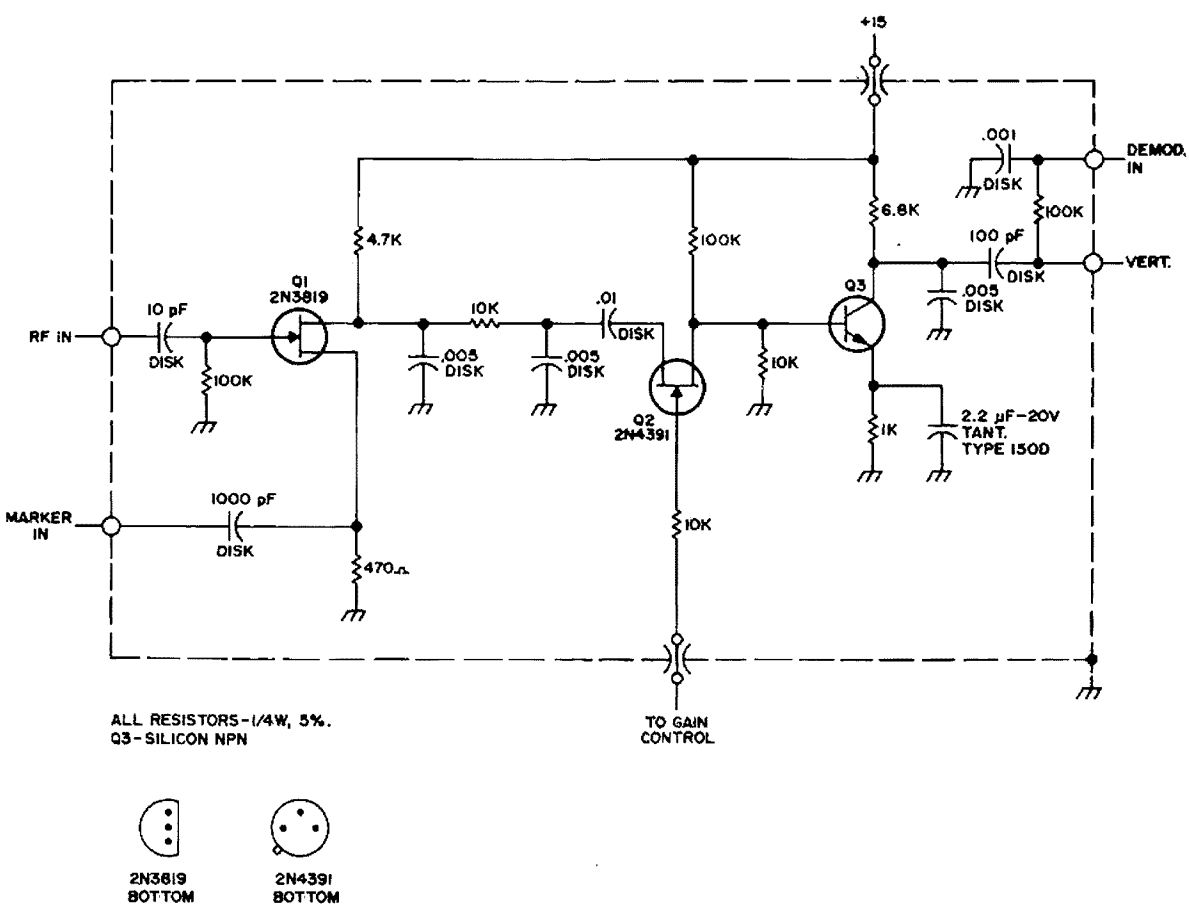
the oscillator output frequency will be constant during the sweep period. The same is true whenever both ramps are of equal amplitude, except that the output will be a steady voltage other than zero. Alsc note that the resultant ramp could have a negative slope if the 'stop' input is lower than the 'start' input, and the oscillator would ob-

The ramp and blanking generator pc assembly. The leads going to external points will go in the holes visible on the board.

viously sweep down in frequency rather than up.

The schematic for the ramp generator is shown in Fig. 5. Operational amplifiers A1 and A2 form a triangle wave generator with A1 acting as a threshold detector and A2 as an integrator. One half of the triangle (negative-going) represents the sweep period while the other half represents the retrace time. Since a square wave is generated at the output of A1, we have a convenient source of blanking voltage built right in. This signal is positive during the sweep period and is connected to the band switch when Swept I (blanked retrace) operation is selected. During retrace the square wave drops to zero and actually disconnects the tank circuit until the next sweep starts. An emitter-follower, Q3, buffers the square wave output for external use.

The output of inverting amplifier A3 is a positive-going ramp during the sweep period and is used for both the 'stop' signal and horizontal sweep for the oscilloscope. Since an additional inversion takes place in the output of A4, the negative-going ramp at this point is used as the 'start' signal. These two ramps are applied across front panel controls which have 6:1 reduction drives and are fitted with dials calibrated in frequency for the five operating bands. The outputs from these two pots are fed to summing amplifier Q1, where the output will be the resultant ramp we discussed above. Because the output Q1 is in the negative region (PNP



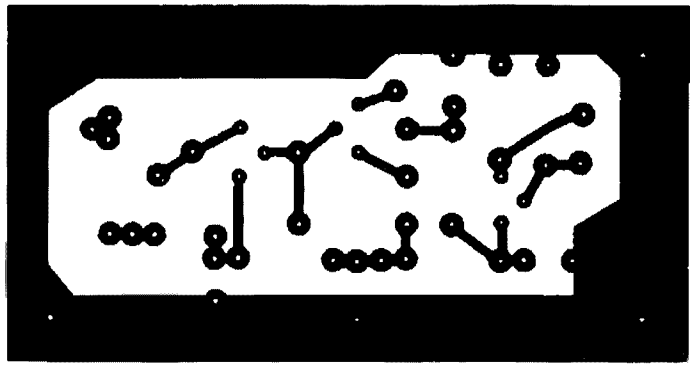


Fig. 8. Post-injection marker circuit with dc gain control of marker size.

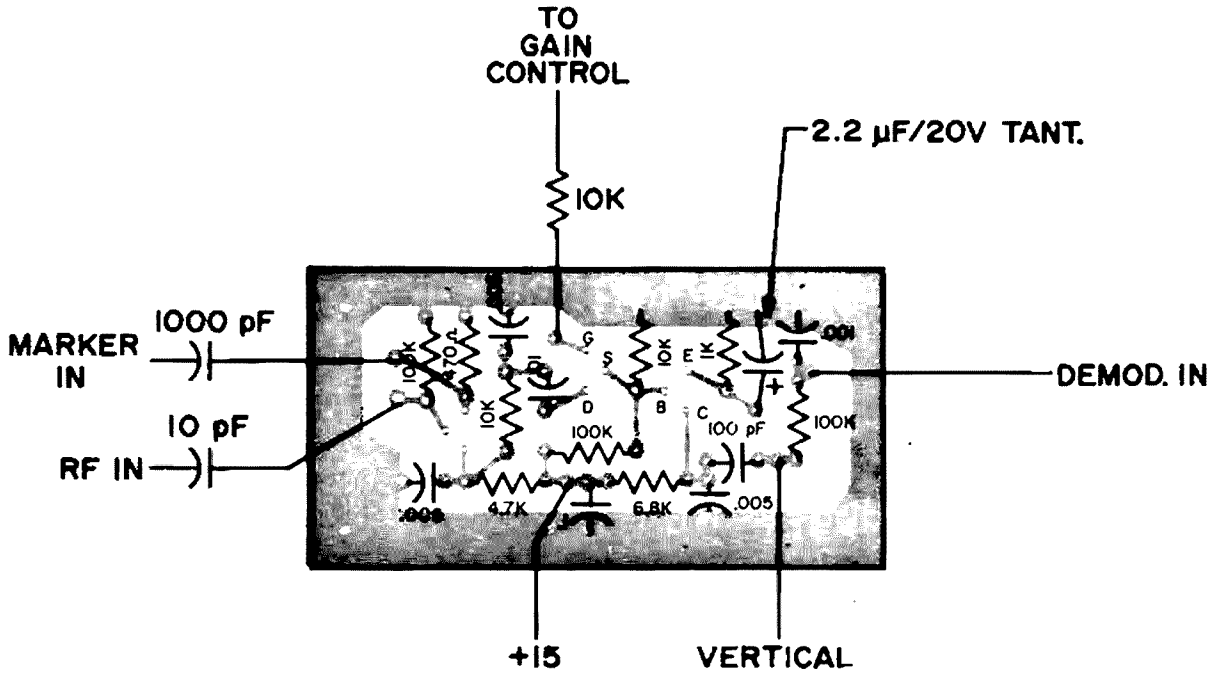

Fig. .9. (A) Foil side of mixer/amplifier pc board. (B) Location of parts on component side.

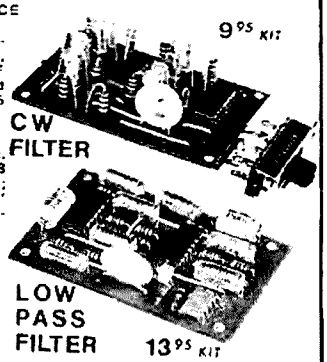
transistor), a second common-base (NPN) amplifier is used to shift the output back to where it will always be positive.

The ramp and blanking generator is constructed on a pc board 2.6 x 4.1 in. in size. For convenience, all the trimmer resistors were mounted along one edge. As seen in the photo, this board was mounted by means of two small brackets in a vertical position with the trimmers facing up. To simplify pattern layout, unused pins 1, 5 and 8 on each of the four 741 opamps were clipped off right at the case. Color-coded wires were connected to all necessary points on the board before it was mounted, with the leads made long enough to reach their destinations. For those interested in building this unit, a detailed procedure for setting up the ramp generator will be given later.

The Mixer/Amplifier



In order to provide a means for displaying frequency markers, a mixer and amplifier circuit was built into the sweep generator. The schematic for this circuit is shown in Fig. 6. A marker generator was not included inside the sweeper because other rf generators were available for use as markers and the added expense seemed unnecessary. Because the mixer board was to be installed inside a shielded box, dc gain control was resorted to as with the band switching discussed earlier. A 2N4391 is used as a variable resistor to control the signal input to the amplifier stage. This in turn controls the size of the marker being displayed on the curve. A 2N3819 FET is used in a simple mixer circuit which worked the best of several tried. Incidentally, the PNP and NPN

ACTIVE AUDIO FILTERS

IC'S FOR SUPER HIGH PERFORMANCE CW FILTER:
Get razor sharp selectivity. No impedance matching! BW (selectable) 180 Hz, 110 Hz and 80 Hz; Center frequency ..F = 750 Hz. Skirts 60 db down at ½F and 2F 4 op amps, 2"X3" PC board. $12.95 wired, tested, guaranteed.

LOW PASS FILTER:
Resistors set cutoff 500 Hz to 20. kHz. Factory set to 2.5 KHz. Rolloff max 48 db/pct. min 40. Input imp 1M; Load>2K, Gain = 1 5 op amps, 2"X3" PC board $15.95 wired, tested, guaranteed.

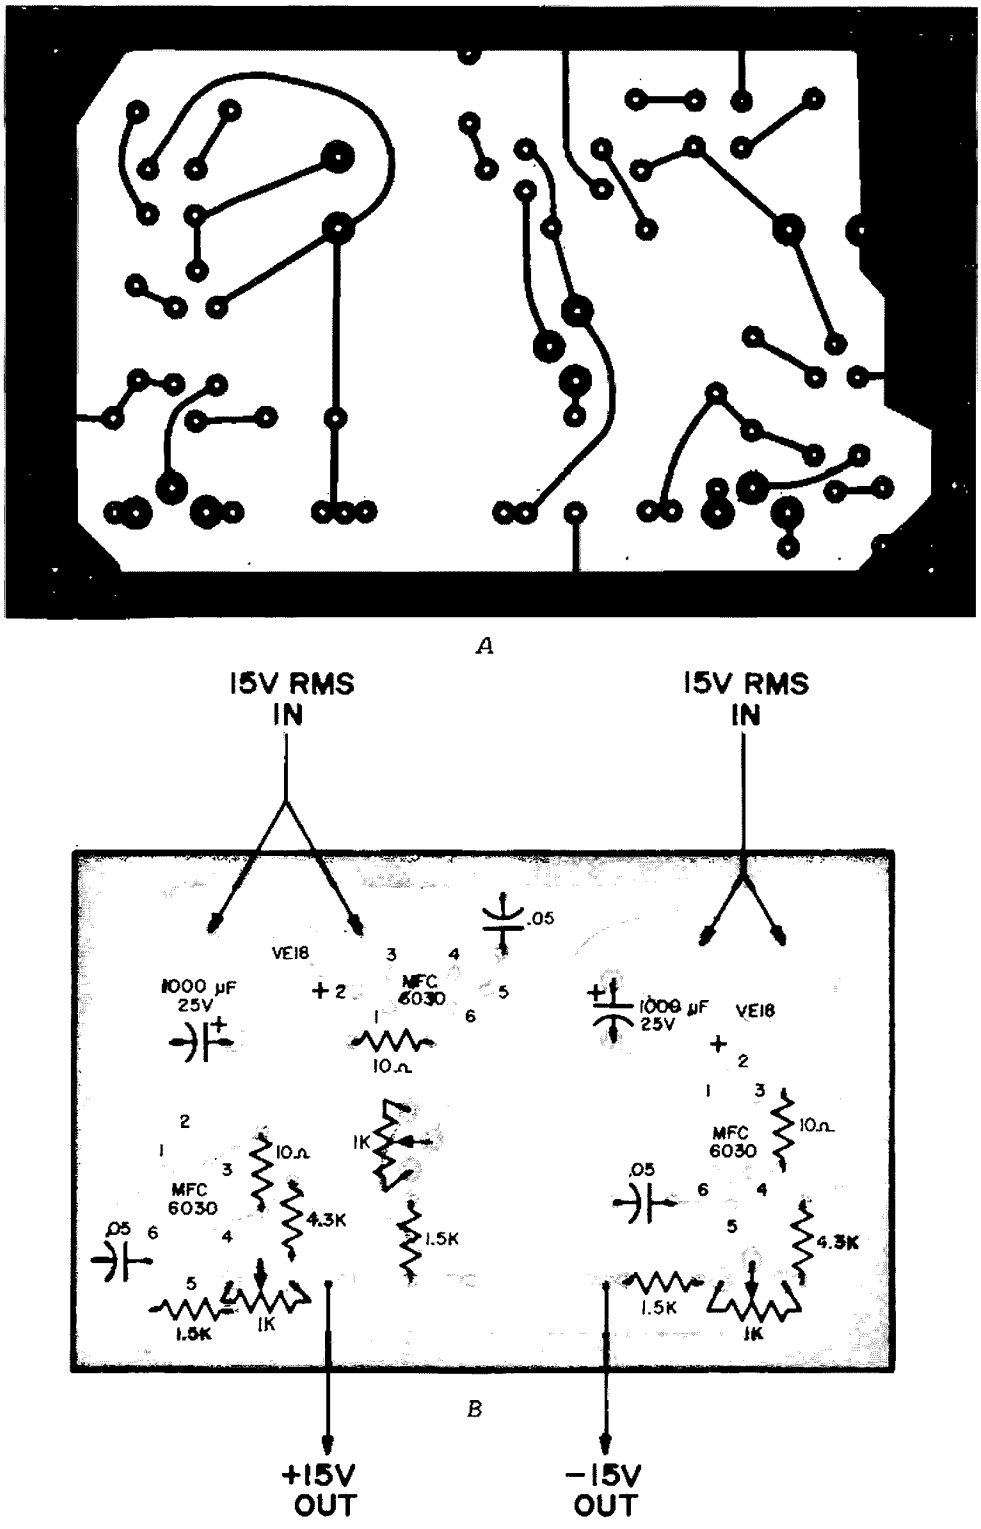

Fig. 11. (A) Foil side of power supply PC board. (B) Location of parts on component side.

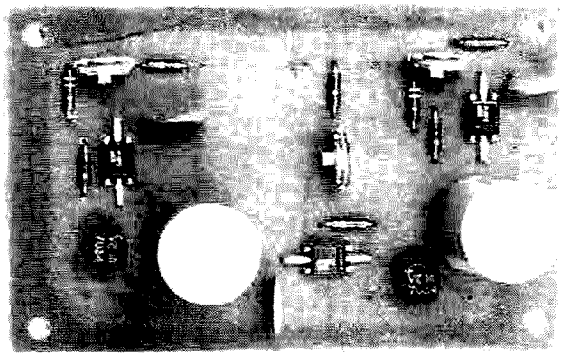

aluminum box. Note that here again some of the components are mounted between the board and their external connectors. These include both the 10 pF and 100 pF input capacitors to the 2N3819 and the 10 KΩ resistor going to the gate of the 2N4391.

The Power Supply

Figure 7 is a schematic for the power supply. Voltage requirements for the sweep generator are +15V, −15V and +5V dc. The current drawn by any of the above circuits runs no more than 30 or 40 mA maximum,

making the use of small IC voltage regulators ideal. Motorola MFC6030 (plastic) regulators are used in each supply and are overload protected against accidental short circuit. Varo type VE18 molded bridge rectifiers, together with 1000 μF filter capacitors, supply the dc input to the regulators. The +15V and +5V regulators are both fed from the same source. The power transformer was a surplus unit with a 30V CT secondary. The center tap was uncovered and the two leads separated so as to provide two independent 15V windings. A small trimmer is provided in each supply for voltage adjustment.

The pc board for the power supply is 2.6 x 4.1 in. All components but the transformer are mounted on the board. The transformer is mounted directly on the chassis. Relative placement of the various components making up the complete generator can be seen quite clearly in the photo.

The power supply pc assembly.

Control Circuits

Figure 8 is the wiring diagram for the control circuitry. Note that for CW operation of the generator, a dc voltage is applied to the varactor by way of the Start pot. In order for the dial calibration to be valid in either mode, the dc level applied to the control must be exactly the same as the peak amplitude of the ramp during swept operation. As will be explained in the set-up procedure, the ramp will vary from a starting point of approximately +1.4V and peak at +12V. Resistor R1 in series with the +15V line is selected for a +12V level at the high end of the pot. R2 is selected for a level of +1.4V at the low end. The reason for the offset of 1.4V at the low end is because the

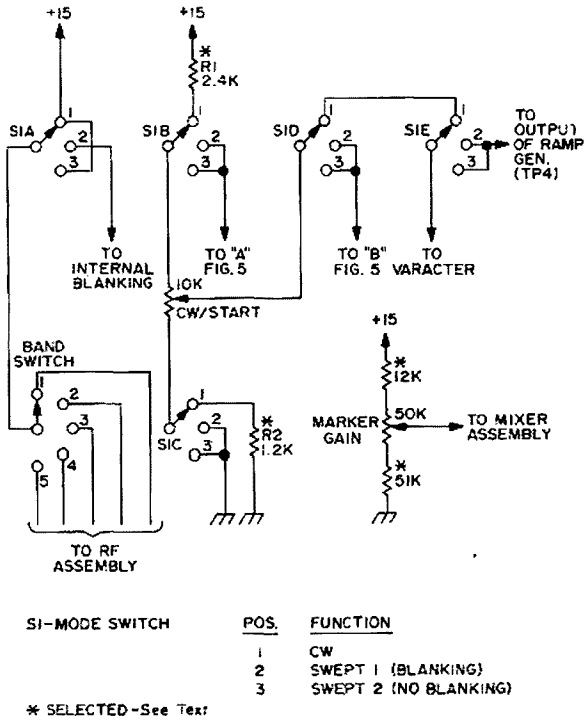

Fig. 12 Control circuit wiring schematic.

pin to which the tuning diode is connected at the MC1648, sits at this level. The source of this bias is the drop developed across two forward-biased junctions within the IC and not from any external source. Once these dc levels have been set for CW with the fixed resistors, the ramp can be made to match by means of the trimmers in the ramp generator circuit.

The rest of the control circuitry is quite straightforward. In position 2 (Swept 1) of the mode switch, positive pulses from the ramp generator are fed to the band switch during the sweep period. When retrace occurs, the pulse drops to zero and the oscillator shuts off until the next sweep starts. In the CW and Swept 2 positions of the mode switch, a steady +15V is applied to the band switch and the oscillator runs continuously.

The final function performed by the mode switch is to route the dc for CW or the ramp for swept operation to the tuning diode. The two fixed resistors are mounted point-to-point behind the panel since all points are readily accessible within every short distances. The fixed resistors associated with the marker gain control are also

mounted the same way behind the panel. The switches are ordinary rotary types and the potentiometers are all ordinary carbon controls. The Start and Stop controls as well as all gain controls have linear tapers. The Sweep Time pot is an audio taper type with built-in switch for ac power.

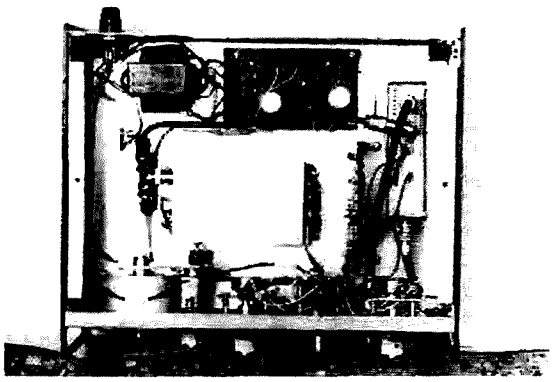
Setting Up the Ramp Generator

For best results, a calibrated dc scope is required to properly adjust the ramp generator. Test points have been provided on the pc board and short pieces of bare wire connected to each of these points make excellent tie points for the scope probe. The circuit may be aligned either before or after installation. The Start, Stop and Sweep Time pots can be connected at the ends of their respective leads if the unit is checked outside the cabinet.

Set all seven trimmers to mid-range. Connect the scope to TP1 and adjust the horizontal for a full sweep of 20 ms. Set the Sweep Time control to minimum resistance and apply power. Some sort of triangular wave should be displayed. Adjust R1 for a 3V p-p amplitude of the waveform. Turn R2 cw until the negative-going portion of the triangle is 20 ms long. Since R1 and R2 interact, you will have to stop occasionally and reset R1 for proper amplitude. Once the ramp is set at 20 ms with the Sweep Time pot at minimum, the slow speed end will automatically be about 5 or 6 seconds with a 1 MΩ pot.

Transfer the scope probe to TP2 where a positive-going ramp should be seen. Set the starting point of the ramp to zero volts by means of R3. Amplitude of this ramp must be 10V. If it is not, go back and adjust R1 slightly until it is. If necessary, reset R2 for 20 ms trace length. As soon as a 10V, 20 ms, zero-based, positive-going ramp has been achieved at TP2, go on to TP3.

At TP3 there should be a negative-going ramp. Once again we require a zero base line or starting point. Adjust R5 to accomplish this. Amplitude should once again be 10V and is controlled by R4. Once you have a 10V, zero-based, negative-going ramp, move on to TP4.



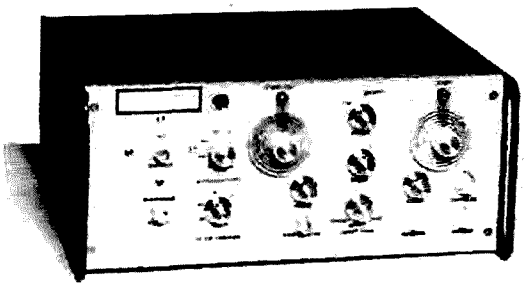
Connect the probe to TP4 and set the Stop control to full cw. The Start pot should be at minimum setting. A positive-going ramp should be present at TP4. By means of trimmer R7, move the ramp up or down until the starting point is approximately +1.4V. Ordinarily the ramp will not go below zero but will flatten out as the positioning control is adjusted. This is due to clipping in the output amplifier. If the ramp generator is going to be used with another type of VCO, the ramp can be set to exactly zero if desired. In our case we can't as explained previously.

Because a substantial amount of capacitance change occurs in the tuning diode up to 12V, the final ramp amplitude is set to 12V by means of R6. Because R6 stretches the signal in a negative direction, R7 will have to be used to reset the base line at 1.4V. Other than for checking tracking between the CW and swept modes, this completes the alignment procedure for the ramp generator.

When the generator is finished, you can check the tracking by observing actual signals at the input to the VCO. Connect the scope probe to the feedthrough capacitor on the VCO assembly that goes to the tuning diode and set the Start control to maximum. Switch rapidly between the CW and Swept 1 positions of the mode switch. The CW input will be a straight line sitting at +12V while the swept input will be a ramp peaking at +12V. Next, turn the Start control to minimum and again compare levels. If the Stop control is also at minimum, both signals will be straight lines at +1.4V. If there is any substantial difference between the two modes, use R6 and R7 on the generator board to make the ramp agree with the dc levels. That completes all phases of the ramp set-up procedure.

Construction

The cabinet used here is one manufactured by Sorensen Electronics in their Mod-U-Line series. These are the most reasonably priced instrument enclosures I've come across so far and I've used them for several projects. This one is a Model MCH-5129 with a CP-129 chassis plate.



This bird's eye view of the interior shows the location of all major assemblies.

Total cost of the enclosure is around $22. Dimensions are: 5¼ in. high by 12 in. wide by 9 in. deep.

The 5-step attenuator was picked up surplus from Fertik's Electronics for about $10. It is well made and designed for 50Ω systems operating up to 1 GHz. It has an integral female BNC output connector on the front face along with four threaded mounting holes for ease of installation. The input connector is a BNC male at the end of a short piece of coax.

All rf assemblies are interconnected inside the cabinet by means of coax cables. This is clearly evident in the photo.

The Start and Stop pots were mounted on brackets behind the front panel so that Jackson Brothers type 4511/DAF reduction drives could be installed for easier tuning. The two circular dials are slightly under 2 in. in diameter and were cut from sheet plastic. While operating in the CW mode, one of these was calibrated in pencil to provide a pattern for the finished product. A master

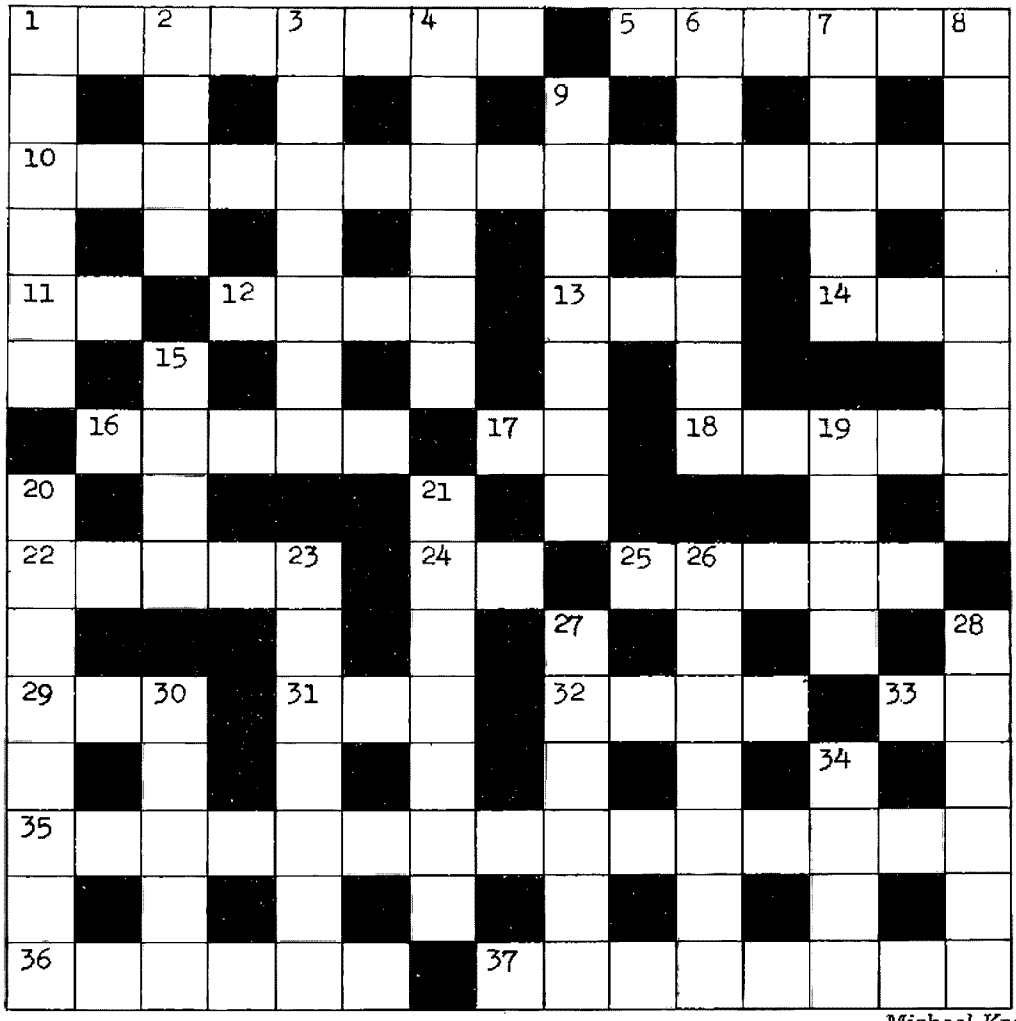
was laid out using Rubylith® film and rub-on numbers. A negative of this was then made using 3M reversing film. From the negative a finished set of dials was printed on aluminum material of the presensitized variety. These were cut out and stuck to the plastic by means of their own pressure-sensitive adhesive backing. The nameplate was made from the same material. The two index pointers are clear plastic with hairlines scored on the inside surface. They are mounted on spacers directly over each dial. All remaining labeling was done with tub-on lettering.

Summary

It is assumed that anyone contemplating construction of an instrument like this is thoroughly familiar with the use of sweep generators so no instructions will be given here. You should find the generator quite useful for making narrow sweep displays such as those for filter response. The ability to control sweep speed is an asset where slow speeds are required. Although only one marker input is provided for, a comb is sometimes useful and can be generated by your crystal calibrator or other square wave source and fed into the marker input. Input level to the mixer should be kept below 100 mV in general since no input gain control is provided.



Purchasing parts is often one of the greatest problems encountered with a project of this nature. In some cases, as with Wescom, minimum billing is a way of life and makes small purchases nigh impossible even though the eventual per piece price is very low. Since I generally buy in larger quantities than needed, I may be able to help out with some of the parts if any of you are really desperate. At any rate, I hope you have found this worthwhile, and to those of you who plan to build the sweep generator – best of luck. . . .K4DHC

ACROSS

1. The amount of opposite magnetomotive force necessary to eliminate residual magnetism.
5. Devices used for determining whether a specified dimension is within specified limits.
10. Describes how a control system or an individual unit carries on with respect to time. (2 wds).
11. No Connection. Abbr.
12. Prefix meaning one-billionth.
13. Explosive.
14. Body of water.
16. A device having two electrodes, the cathode and the plate.
17. Outside dimension. Abbr.
18. The maximum useful distance of a radar or radio transmitter.
22. The medium that was once supposed to fill all space and through which radio, heat, and light waves were supposed to travel.
24. A type of loss.
25. A ladle.
29. Unit of electrical resistance.
31. Document. Abbr.
32. Measure of land.
33. Near.
35. In control systems, the reference input minus the primary feedback.
36. A revolving plate mounted at the front of some television cameras carrying two or more lenses, for rapid interchange.
37. One of a group of gases that will not combine with another element (2 wds).

DOWN

1. A squelch circuit. (P1) 2. Indefinite periods of time. 3. A signal which initiates or triggers an action in the device that receives the signal.
4. A quantity having magnitude and direction.
6. A fitting designed to change the terminal arrangement of a jack, plug or socket.
8. The crossarm separating the parallel wire elements of an antenna.
9. A five-electrode electron tube.
15. A microwave antenna, usually shaped like a parabola.
19. Inert gas used in some electron tubes.
20. Increasing the intensity of sounds.
21. An electronic path between two or more points capable of providing a number of channels.
23. To emit rays from a center source.
26. A wave of constant amplitude, frequency, and phase which can be modulated by changing amplitude, frequency, or phase.
27. The difference between an actual operating point and the point or condition where a failure to operate properly will occur.
28. An off-on application of power.
30. Instrument used formaking electrical measurements.
34. Tight fit.

Solution page 228

LETTERS CONT.

Some time ago, when I wrote you in the context of "Caveat Emptor," I agreed with myself that it was my last excursion into the controversial world of amateur radio. Tiling with windmills can be pretty exhausting, as Don Quixote discovered, and the quasi-independence of various amateur groups makes conciliatory efforts equally debilitating; if not more so.

However, as I see another divisive tempest brewing among amateurs, this time in the FM repeater ranks, I cannot in good conscience ignore it. At least without pointing out that the present conflicts are symptomatic of the very actions that lost much of the available space, in other bands, for us. And with more emphasis, has helped to persuade the FCC that we can't get together, don't know what we really want, don't use what we have — all to the end of more regulation and fewer privileges.

Now we see the familiar dog-eat-dog pattern developing in the relatively sophisticated (technically) world of the FM repeater. Courtesy and conciliation seem again to be unknown quantities in the ham world, insofar as promotion and operation of repeaters in general is concerned. I'm sure that most users, like myself, try to remember that there may be others "waiting on the line," and so keep an ear out for breakers. But I've already heard the type of stuff that pretty much ruined phone for most of us on 20 and 75. And now it seems that the brute force output philosophy is being applied to repeaters.

So I suppose this is a plea for maturity in judgment and for common sense in approach. Surely we all understand that there are no private frequencies or coverage areas. Surely we are sufficiently advanced in techniques — either with respect to antenna patterns or with respect to triggering — to find ways and means to reduce QRM between repeaters to a minimum.

Let's not drop the ball *this* time! Hell's bells, if the associations and individuals concerned will only get together on a non-power-politics basis, we can stop the fragmentation and begin to achieve cohesion. And realize the real potential of FM repeaters.

Al Smith W1GAA/K3ZMS

Well, Al, I have a feeling that your erudite and polite request which is aimed at a select few will not get their attention. They are much too involved with the alligators snapping at their ass, which is an apropos expresssion for repeater squabbles.

One of the functions of the Repeater Bulletin — actually one of the major functions in my view (and the Bulletin is obviously an expression of my view, though more by default than intention — if others would learn to express themselves in writing as well as they do with amplifiers and insulting remarks on repeaters I think that more progress could be made) — oh, yes, the Bulletin function is to throw light on bad situations as they develop with the hope that the scurvy characters who are working so diligently to make things miserable for others would scurry away from the light.

If you get on the air and use the repeaters quite a lot, Al, you'll find that the battles in our ranks are, in perspective, quite minor. Perhaps the reporting of them in detail in the Bulletin has made them seem more important than they are. Listening to one or two repeaters can give you a biased perspective — like the Marcus-ARRL machine KGQ could give someone a very bad idea of how things are — ditto the KHB machine in Weston. I doubt if you'll hear much negative on many of the other repeaters.

You should keep in mind that, all in all, repeaters in New England are so far ahead of the rest of the country that our situation is a model for the whole world. This does not mean that we can't improve or that we should stop trying to clean up the little pockets of childishness that are bothering us.

May I take issue with you regarding the "ruined" 20 and 75 meter bands? The only big problems that I see with these bands are the General Class segments which are generally horrible. Even with a BIG signal I find these parts of the band depressing and I head back for the QRM-free two meter repeaters.

There are times when the Advanced portion of these bands gets filled up, but for the most part I find little difficulty in making contacts with about the same level of QRM as I have been used to for all of the sideband years. When I remember back to the old AM days I am ever thankful — for there is no comparison.

I do not think that the FCC did the amateurs any favors at all when they established the split phone bands. It obviously has had little effect in getting amateurs to change their grade of license. I suspect that this has helped FM to grow — perhaps a lot more than suspected. The intensive QRM of the General part of 20m is enough to get anyone to think in terms of looking for something better. The almost total lack of QRM on 2m FM stands out as a shining beacon to the beleagured low banders.

The arrogant and the childish will always have their problems — with their own repeaters — with the press, and I don't know of any way for these difficulties to be resolved since psychotherapy seems the only out and it isn't going to be used. No, I think that there will always be some areas of controversy. It is up to the readers to decide which sides of the controversy are most in need of electric shock treatment. On this point, the switch to solid state leaves some doubts since twelve volts will never impress anyone like 2000 volts will. Looking on the bright side — all those old Gil cartoons on Switch To Safety can at last be put in the ARRL museum.

In the long run we are all headed for a listing in QST under Silent Keys. In my mind, the measure of an amateur is how much fun he was able to bring to others. 1200 watts output on 79 brings fun only to the chap with the fiendish gleam in his eye as he watches his output meter. The alligator he creates brings un-fun to everyone else. Badmouthing over the air may gratify the chap who is doing it, but it is unpleasant for most listeners.

I'm the proud possessor of a used (new to me) Hallicrafters SR-42A. I'd love to FM the thing, and I'm really curious about any other things I could do to it to make it even better.

I'd appreciate any help you could give me on this. Might be a problem getting enough deviation, since the vfo is in the 20 MHz area, as are the crystals for the thing.

Many thanks for any help you can give me. And keep up the fine work in 73 — it's the one ham magazine that makes the hobby fun, as opposed to an oldtimer's "remember when...." journal.

George Lesch WB2ENP
Staten Island NY

Can anyone bail old George out?

I am curious to know what the message from Wayne (BIMEK FUSAJ CAQOF) on the "contents" page of the September '72 issue. Would appreciate any light you might shed on this matter.

Reggie W5SSB

Naval crypto prefix to indicate cypher being used.

Please enter my name for a one year subscription to 73. I've been buying it on the newsstand for about a year and it has definitely been the best magazine I never subscribed to.

I hope you don't mind my not sending the coupon which forms such an integral part of your last issue. I detest cutting up magazines for the purpose of removing coupons almost as much as I detest others cutting up my magazines for the purpose of removing coupons. There almost always is a good article worthy of saving on the reverse. And when there is not, there is an advertisement which I want to keep for reference. Is there a publishers' conspiracy against those who want to keep their magazine collection intact?

Bill Garfield's "Poor Man's Transcanner" in the August issue brought to mind a letter from Regency which I got from a friend about two years ago. It provides some conversion infor-

CONTINUED

mation not provided by Bill. Whether or not the changes will improve the sensitivity I cannot say. The earlier units may have had trouble tuning down to the 2m band and the current ones may do so with no difficulty at all. No matter what the case, your readers may appreciate having the supplemental details. I doubt if Regency would have any objections to your quoting the letter, especially since it can do nothing but help their sales.

Robert E. Tashjian
Canoga Park CA

Here are the details from the Regency letter:

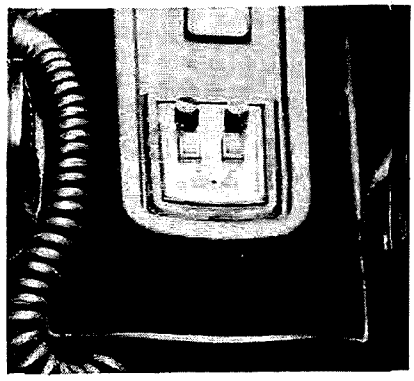
Subject: TMR-H Series
in Two Meter Band

1. Modifications that are necessary to move this unit into 146–148 MHz portion of the 2 meter amateur band.
A. Replace three capacitors and retune the RF section.
C201 replaced with a 12 pf.
C203 & C206 replaced with 6.8 pf.
Retune L201, L202 & L203
Note: The ceramic filter presently being used is only proper for NBFM (5 KC deviation). If wide band FM is employed, the filter would have to be replaced (CF455-AP should be adequate). The quadrature coil may have to be swamped more than it is now.
B. You can expect 0.7 or better, microvolt sensitivity for 20 DB of quieting.
C. By adding one wire, terminals 3 and 4 can be utilized for *muting* purposes, connect terminal 3 to the junction of the blue wire and R310 (33k) on the scanner board. If terminal 3 is then externally switched to terminal 4 during transmission, the receiver is effectively muted or disabled.
D. Two germanium diodes, back-to-back, soldered across the receiver's input, will provide sufficient RF transistor protection.

Each time details of an airline hijacking appear in a newspaper, probably three more are committed. And, at least two guys have been killed in an Italian restaurant since "The Godfather" came out. But never before have I seen published step-by-step instructions for killing hams.

The "Cigar Tube" article on page 28 in the September 1972 issue, suggests forming a ground connection through your body by holding the chassis with one hand and the damn tube with the other hand.

Well, even if the .1 Cap isn't shorted and the thing isn't built wrong, at any frequency over a few cycles, that .1 Mfd impedance starts looking mighty small in comparison with your body resistance. Just try accidentally probing an RF output or the output of your hi-fi set, using your arms as a ground return. Pffft!



Please edit these articles more carefully and print some sort of retraction to the paragraph in question in the next possible issue. How about a signal injector that will only work with one arm behind your back?

Gary Budiansky WA1MCR
Acton MA

Sorry, but something strange comes over us every time we publish a "tube" article.

I noted with interest the picture and article on page 50 of July 73. I had the same problem with a 1969 Fiat 124 coupe. I use a Motorola D-43 trunk-mount and had the control head between the driver's seat and the console. When I bought a new Fiat 124 Spyder, I decided to do it right.

As you can see from the enclosed photo, the control head is built into the rear ashtray of the console. The purpose was twofold: to make the existence of the rig a secret (I park in downtown Boston daily) and to preserve the interior "esthetic beauty" of the 124 Spyder.

The cable seen at the bottom of the enlargement runs to the D-43 in the trunk. The microphone cable can also be seen going under the console into the control head. By running all cables under and inside the console, I have been able to avoid drilling holes in it. A twisted pair runs from the control head to the BC receiver's speaker. Another pair run forward to the engine compartment to activate the 12VDC 80Amp relay which turns everything on and off. The controls are pretty straightforward: volume, squelch, green light power on, red light for transmit, on-off switch and frequency select switch. The antenna incidentally is a Larsen 5/8 wave mounted on the trunk.

Barry W. Fox K3IWW/1
Ayer MA

On a rainy afternoon last June, I had the pleasure to visit you and the staff of 73. I wish to extend my sincere appreciation for your time and personal interest extended to a fellow amateur by yourself and staff.

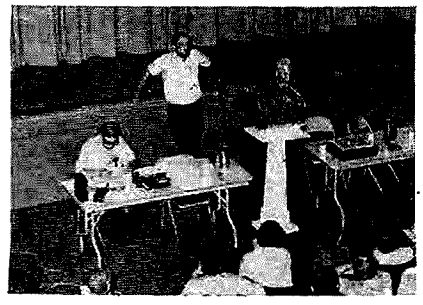
Although the state of Mississippi may be remote on your itinerary, I would like to extend to you the warm hospitality I received in New England, should you chance this way.

As I mentioned to you, Wayne, I have followed your articles over the years through thick and thin with avid interest.

Laurence P. Williams W5IIQ
Ocean Springs MS

Our pleasure!

From time to time you mention foreign hams having trouble getting electronic equipment because of lack of funds or import problems.



I have a General Electronics, Inc., multiphase Exciter MOD 20A with a BC 458 modified for use as a VFO including instruction manual for the 20A. I would be pleased to donate this equipment and pay postage if you can suggest anyone needing it.

David D. Blackmer WA6UNK
Rt. 1, Willow Road
Nipomo CA 93444

Suggest you write to B.A.N. Raju, Radio Constr. & Development Unit, Civil Aviation Department, Safdarjung, New Delhi, India for name and data on getting rig to them through customs. If anyone knows amateurs in any countries who would appreciate and use some older gear please let 73 know – and if you have gear, why let it sit in the closet – why not get it into needy hands?

73 is by far the best. I let my QST subscription run out so I could subscribe to 73 for two years instead of just one.

J E. Babeckis WB9GXB
Chicago ILL

Here is a photo of the Baldwin Park frequency coordination meeting held on 9 September '72. I hope it can be of some use to you. John Griggs W6KW is at the mike and Skip Clark WB6TXX is leaning against the stage.

Thank you for your motivation of the people here on the west coast. I feel that it was you who got us moving, and temporarily out of the grips of the FCC.

AMATEUR RADIO AND EDUCATION IN YUGOSLAVIA

A. Stipanic YU3BH
Secretary SRJ

The Union of Radio-Amateurs of Yugoslavia (Savez radioamatera Yugoslavije – SRJ) is one of the youngest national organizations of radio amateurs in Europe. In 1971 it will celebrate the twenty-fifth anniversary of its foundation. Today, SRJ has in its ranks about 42,000 members, and among these are some 10,000 licensed radio operators. It is evident that the technical education of such a large number of members and radio operators in a relatively short period of time has required considerable efforts on the part of that organization, and special working methods, which may be summarized as follows:

The basic organizational unit of the SRJ is the radio club. At present there are 415 radio clubs and 348 branch clubs in Yugoslavia. These are organized within the radio amateur unions of 6 Federal Republics and 2 provinces. These various unions are then grouped together into one national organization – the SRJ.

Following this organizational scheme, the SRJ represents radio amateurs of Yugoslavia at a federal level, uniting them and establishing a policy of developing amateur radio throughout the country as a whole.

All the radio clubs, the unions of radio amateurs of the federal republics and provinces and the SRJ itself, are headed by committes which are elected every two or three years by the members of the organization they represent, or by assemblies in which every member can participate. There are no representatives of local, republic or federal state authorities in these committees.

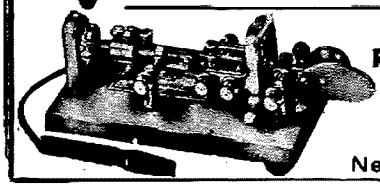
Every licensed radio amateur in Yugoslavia must be a member of a Yugoslav radio club. This is provided for by law, and hence the SRJ is in a position to unify the educational policy of radio amateurs throughout the country.

The basic methods of education are evening courses in electronics, radio techniques, Morse code, etc., which are usually organized by the radio clubs or their branches, and sometimes also by public schools, universities, factories, or other appropriate institutions in which sufficient candidates can be found to justify the preparation of such a course.

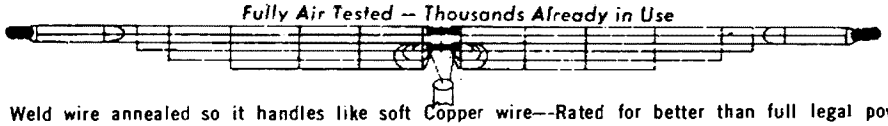
The SRJ has established a special plan for these courses, laying down a certain minimum knowledge required to become a radio operator within a club or private amateur radio station.

Under Yugoslav law, the SRJ has the right and duty to form examination boards, the members of which are experienced Class I or II operators. No representatives of the state authorities sit on these boards, and the operators one can hear every day, under YU or YT call-signs, are the exclusive products of the education acquired in radio clubs by the members of the SRJ.

In addition to this, we also have special seminaries and courses for so-called constructors, to qualify them as lecturers at evening courses in radio clubs. These seminaries, lasting from 10 to 20 days, and courses for lecturers, are usually organized in summer camps by the unions of radio amateurs of the federal republics and provinces, during the vacation period. In addition to theoretical lectures, participants quite often build a practical instrument, such as a converter, antenna, etc., which they use in their own radio clubs to improve the equipment they already possess. Sometimes seminaries are also held for the special branches of amateur radio. To cite a few examples only: fox hunting, VHF and UHF work by meteor scatter, moonbounce, and so on.



I must stress that all the work of lecturers at evening courses, seminaries or other forms of education of radio amateurs in Yugoslavia, is on a strictly voluntary basis.



All the foregoing is merely what may be termed the *technical* aspect of the work. To teach radio amateurs to know their equip-

ment thoroughly and to learn how to work efficiently in the field of amateur radio, special care is dedicated to educating future radio amateurs in "ham spirit," to ensure that they will ultimately become true ambassadors for peace amongst all the nations of the world.

That is one of the reasons that we have on our programme of examinations several questions concerning the international amateur radio movement, its organization, etc.

That is, briefly, what I wished to say about the education of radio amateurs in Yugoslavia. It is understandable that all this work also represents a noteworthy contribution by radio amateurs in aiding the education of youth. This is, in fact, one way – and a fine way – of raising the general technical and humanitarian level of young people.

I must here also underline that many elementary schools, as well as some high schools, have assimilated certain parts of the educational programme of the SRJ into their own technical education programmes. The practical consequence of this procedure is that the SRJ has its radio clubs in all universities in Yugoslavia and in many high schools. Several hundred teachers and professors are radio amateurs, and it is obvious that they seize every opportunity to influence their students to enter amateur radio.

SRJ has organized a special activity, called "Spring on the Radio Waves," when groups of radio amateurs with their stations visit public schools to transmit their prepared programmes to other schools in the country. There is no doubt that this also offers another real opportunity to inspire young people to join amateur radio.

Furthermore, television, radio, newspapers and various magazines often broadcast or publish articles on amateur radio. This is especially the case when radio amateurs have shown their ability to help at times of national disaster. You will all remember the earthquakes in Skopje, and Banja Luka and the floods in Zagreb, where radio amateurs were the only ones able to link up the stricken areas with the rest of the world. . . .YU3BH

K. Slomceynski SP5HS
Secretary PZK

THE EDUCATION OF RADIO AMATEURS IN POLAND

The Polish Amateur Radio Society (Polski Zwiazek Krotkofalowcow – PZK) is continuing its training programme in close cooperation with the Polish PTT Administration. This cooperation is based on the well-known fact that the field of amateur radio is one of the best training schools for highly qualified radio and telecommunication specialists. And what is also important – this specialized training is provided by the amateurs themselves, without any expensive buildings, equipment or teachers.

The PZK also carries out its amateur educational programme in cooperation and alliance with two other youth organizations in Poland: the Polish Boy-Scouts (ZHP) and the League of Home Defence (LOK). The first of these unites hundreds of thousands of schoolboys and girls; the second has multiple activities, such as motoring, competition shooting, the building of ship or aircraft models, telephone and radio training, etc. Each has its own radio clubs, operating amateur radio stations.

The educational programme of the PZK is orientated in the following three directions:

1. The propagation of the basic principles of amateur radio among a wide public, especially among boy scouts, and schoolchildren.
2. The technical and general education of newcomers, both short-wave listeners and novices;
3. The specialized training of experienced amateurs, helping them to be "au courant" with the latest state of the art in telecommunications.

The first line of action is administered by the Public Relations Commission of the PZK HQ Council, directed by Vice-President SP5JE who is Director of the Technical Department in the Polish PTT Ministry. The commonly used methods are: amateur programmes in broadcasting and television, articles concerning amateur radio in newspapers and popular magazines, and PZK's own publications and leaflets, such as: *"How to become a Radio Amateur," "Amateur Radio"* (intended for boy scouts), etc.

At the end of 1970 the second TV programme came into operation in Poland and the PZK has commenced weekly amateur lectures at a popular level. In addition, the weekly bulletins, dedicated not only to amateurs, are transmitted on 80 and 40 meters by our HQ station, SP5PZK.

The most important activity in the second direction is aimed at converting the young newcomer, who is just starting to listen in on the amateur bands, into an experienced amateur operator ready to construct a complete do-it-yourself station and to operate it under various conditions. This part of our programme is supervised by the HQ Commission for Amateur Education, and managed by PZK Vice-President SP5JH (who is also Chief of Communications in the Boy-Scouts' Headquarters).

The newcomer's training programme is based on the fact that our Society is responsible not only for strictly technical education, but also helps schools and parents in the general education of young people.

The training programmes of the PZK are officially accepted by the PTT Ministry and are coordinated with the official requirements for amateur examinations.

. . .SP5HS

Herbert Götze, DM2HGO
(President of the Radio Club of the D.D.R.)

AMATEUR RADIO TRAINING IN THE GERMAN DEMOCRATIC REPUBLIC

The training activities of the German Democratic Republic Radio Club are based on the amateur radio regulations first issued by our national telecommunication authority, the "Ministry for Post and Telecommunications." The present version came into force in 1965. We consider that these regulations, which were worked out in cooperation with experienced radio amateurs, are very liberal and progressive. Our view has been confirmed by many OM's from other countries.

As from the age of 14, every citizen may become a radio amateur – i.e., may be granted a radio amateur license. In some cases, this is even possible at an earlier age.

Finally, the fourth permit is assigned to radio amateurs who only wish to use radioteleprinting (RTTY). No telegraphy ability is required here either, merely the proof of competence in the operation of a teleprinter.

I have begun this explanation about our amateur radio regulations because from these arise the demands for the training of radio amateurs. In conformity with the subject of the examinations comprised within these Regulations, the Radio Club of the G.D.R. has worked out a comprehensive and unitary programme of training, which reflects every aspect of radio amateur activity, both theoretical and practical. Training schedules are developed in the clubs, based on this programme, which include a thematic and time arrangement.

When selecting the literature, we restricted ourselves to a few publications available everywhere in the Republic, so as to maintain unity with the standard of training. Moreoever, extensive documentation exists concerning amateur radio in the G.D.R., Foreigners who have been resident in the Republic for a long period, such as students at our universities or high schools, or mechanics and businessmen in foreign firms, can also get an amateur radio license, free of charge and without membership of our Club being obligatory. To complete the picture, I would just mention that foreigners who are the guests of our Republic and who already hold an amateur radio license in their home country, are also granted a guest's license.

Our amateur-radio Regulations provide for four classes of permit: Class "2" is provided for newcomers and requires an ability of only 40 letters per minute CW and a relatively simple knowledge of radio technology. This license therefore only entitles the holder to work on 80 and 20 meters, with a maximum antenna input of 20 Watts.

The holder who has worked under such conditions for one year may apply for another class of permit, namely, the main class "1." This entitles the holder to work on all bands, in any mode and with a maximum input of 300 Watts.

Another type of permit, considered as a technical license, is for VHF amateurs. CW ability is not required for this class.

some of which is also internationally known, such as *"The Antenna Book"* by Rothammel (DM2ABK) and *"Amateur Radio Practice,"* by the same author, to cite only two examples.

In the booklet series *"The Practical Radio-Amateur,"* of which more than 90 numbers have been issued until now, nearly all the desires and interests of radio amateurs are taken into consideration.

For three years a new book series, *"The Amateur Library"* has been published. In this series, five special works for radio amateurs and amateur electronicians have so far been published. Besides this, the Radio Club of the G.D.R. issues special instructions for amateur construction activities, in which especially approved standard equipment is described in detail. The training programme and the relevant literature for teaching and private study both provide a good basis for an effective amateur radio training.

Training is carried out in our club stations, of which more than 600 exist at present in the Republic. They are to be found within youth-clubs, clubs of various industries and business firms and within the precincts of our own club.

In principle, the future radio amateur, in his training, passes the qualification stage as a receiving amateur. Prior to this, he has already had the opportunity of acquiring a diploma of the Radio Club of the G.D.R., the so-called HADM-Diploma (Heard All DM), by fulfilling simple tasks as a broadcast listener.

Within the qualification stage, as a listening amateur, he may at first be active as a receiving amateur candidate. He is given a listener's number and may benefit from all the facilities offered by the Radio Club to amateurs. The examination, which does not require any knowledge of telegraphy, is passed in a club station before an examining committee, consisting of licensed radio amateurs.

Thereafter, he receives from the radio club a listener's diploma, which entitles him to work as a receiving candidate for two years. Within this period, he may further qualify as a receiving amateur; depending on his inclination, he may qualify for listening activity in all radio amateur bands, including the 2m and 70 cm bands, whether he has knowledge of telegraphy or not.

The club stations are equipped with the financial aid of our union and by that of industries and other institutions.

The sound policy of school education in our state, which, among others, is also reflected by polytechnical training, is a good basis for our young citizens to understand the phenomena of natural science and consequently the secrets of electrotechnics and radio engineering.

A great number of our listeners are young people, which does not mean that there is any limitation to age, for we had the case in Berlin where a 65-year-old engineer qualified as a radio amateur!

In the field of the listener's movement, we have created a possibility for receiving amateurs, having reached corresponding results, to acquire a permanent "master" title or, by means of a competition of limited duration, the title of a so-called "master of the year."

The activities of our radio amateurs are guided, on the part of the radio club, by a special section devoted to youth work and listener's affairs, which is directed by prominent pedagogues, themselves radio amateurs. Needless to say, this technical training goes hand-in-hand with general education and training in citizenship.

In his further advanced training, the receiving amateur qualifies, in the club station or in central courses of the radio club, as a transmitting amateur. Our regulations lay down that, at first, he should cooperate for some time as a radio amateur in one of our club stations, in order to extend his experience and knowledge under the direction of experienced amateurs.

In accordance with these regulations, he can work either as a short-wave or as a VHF amateur. The latter is a type of authorization which, at international level, is known as a Technician's License, for which no telegraph knowledge is required and which is acquired by a great number of experts from the electronic and radio-engineering world, particularly as, in the examination, chief stress is laid on technical matters, in addition

to comprehensive knowledge of the relevant regulations.

Radio amateurs who are knowledgeable and who assist our union in the fulfillment of its duties, have the opportunity of receiving the authorization to operate a private station. This is considered a distinction for good work.

Great value is set on the continuous advanced training of our radio amateurs and neither effort nor money is stinted to this end. By means of our radio amateur technical journal "Funkamateur" and other special series, some of which are licensed eiditions which are also known in other countries, the amateur has the opportunity of qualifying by private study. These series are also available to beginners and are widely read and studied by others interested in technical matters. In addition, meetings of radio amateurs which are organized in club stations, or at district or republic level, offer excellent chances of advanced training in all fields.

We plan to increase the stimulus for continuous perfectioning, by creating an amateur radio master title or qualification degree that can be acquired by the radio-transmitting amateur.

It is taken for granted that participation of our amateurs in competitions organized by our own and foreign unions is also considered an excellent opportunity for advanced training, and both radio receiving and transmitting amateurs make wide use of this means.

Cooperation in the field of national and international amateur radio observation, for which our union issues relevant instructions jointly with competent scientific institutions, is also included in training and advanced training.

We maintain a constant exchange of experience with the unions of socialist countries and would be very glad to enter into an exchange of ideas with other unions too. Unfortunately, it would appear at present that close contacts rarely exist at an official union level, and it is our hope to be able to change this situation by future membership of the I.A.R.U.

Increase the Usefullness of an "APC"

William P. Turner WAØABI
5 Chestnut Court
Saint Peters MO 63376

One of the most common, least expensive, and useful variable capacitors around is the "APC" type. They are available new and used in military surplus as well as in the form of replacement parts. These capacitors are well made and have practically endless uses in any builder's shack.

The major disadvantage of this capacitor is the single bearing design, but this is a problem only in frequency determining circuits such as a vfo. A second and relatively minor disadvantage is the almost universal practice of soldering the rotor tensioning spider to the end of one of the mounting posts. This type construction dictates the grounding of one side of the capacitor. When using an APC in above-ground circuitry it is necessary to insulate the post from metallic portions of the chassis through the use of standoffs, a non-metallic subchassis, or shoulder washers. Very often these alternatives are not in keeping with the desires of the constructor.

Another less cumbersome route is to carefully unsolder the spider and slip a scrap of fishpaper or similar insulation into the void. The same must be done to other legs of the spider even if they are not soldered. Both the rotor and stator are now above ground and may be connected as desired.

A PROFESSIONAL DIGITAL COUNTER

Quite a few articles have appeared in the literaure of the past months, describing digital counters as a brilliant addition to the experimenter's arsenal. Some of these almost stimulated me to action, but there always seemed to be a vital objection to each of them somewhere along the line. A number of these designs required neon bulbs or nixie tubes with the necessary 200V power supply and high-voltage transistors. Some of the logic circuits seemed cumbersome, some of the articles seemed simple enough but were so sketchy that the builder was almost left to start from scratch when confronted with the actual layout and circuit design.

A recent development made it possible to eliminate all these objections and started a labor of love which will be described here. Tung-Sol recently announced a new readout device which is actually a tiny cathode-ray tube. Two tiny filament wires (requiring only 1.6V at 45 mA) supply electrons to bombard a seven-segment digital-8 (See Fig. 1), each of these seven segments being a separate phosphor anode which requires from 12 to 25V at only a few mA. This miniscule power requirement and compact readout tube makes a really small and inexpensive counter possible. It is called the Digivac S/G, and is relatively cheap in small quantities, at $5.30 each. Texas Instruments makes an integrated circuit which takes BCD information from a set of flip-flops, resolves it into seven-segment logic, and drives the Digivac tubes directly with the proper voltages. Another company, General Instrument Corp., even includes the decade counter and driver circuitry in a single IC package. This makes a really tiny counter possible, but at a pretty stiff price for the average ham. This article describes a compromise approach which utilizes the advantages of the Digivac tube to build a compact counter with simple power-supply requirements, but at a rock-bottom cost.

I believe that this layout is the ultimate in tiny counters, when cost is considered. The low voltage requirements of the Digivac tube make it possible to use any old transistors that will block 22V (I took mine off old surplus computer boards) and the least expensive of RTL IC's easily furnish enough drive for our purposes, and will count at better than 10 MHz. The complete 6-digit counter was built on a 4½ x 5½ in. etched board. The board is etched both sides

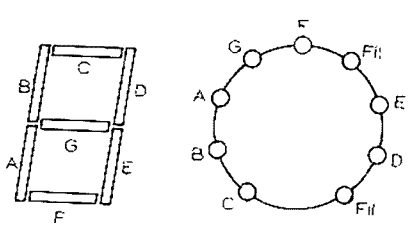

Fig. 1. Anode layout and base diagram of the Digivac S/G readout tube.

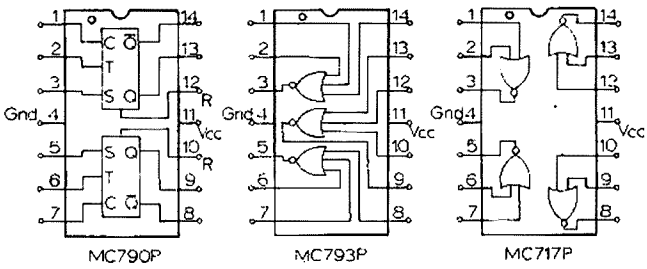

Fig. 2. Basing diagrams of the integrated circuits, as seen from the top of the package.

because of the complexity of the circuit, the clearances for the components are pretty close, and the soldering must be precise to avoid solder bridges to other conductors, but this should not be a real problem with proper equipment. I used a Princess soldering pencil with a 10W element and the finest pointed tip I could find. With this, I soldered all the transistors, diodes, and IC's, both above and below the board, without a heat sink, and didn't ruin a single one.

The logic could be made slightly more simple using *nand* gates or various combinations of *nand* and *nor* gates, but at considerable greater expense. Not counting the transistors and diodes, which I took off old computer boards, the counter cost about $13.00 per digit to build. As each consecutive pair of digits shares one of the IC's, the counter can be built in multiples of two digits – if you only require four digits for the readout on your vfo, you can just lop the board off at that point.

The Digital Logic

The devices used for the actual counting are Motorola MC790P's which contain two J-K flip-flops in one package (Fig. 2). Rather than simply dividing by two, J-K flip-flops make other options possible. Each of these flip-flops has two output pins, each of which can have two states – "high," which is a little over +1V, and "low," which is just a

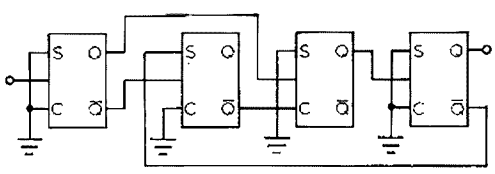

Fig. 3. Connection scheme for the Modulo-ten minimum-hardware circuit.

Table 1
Truth tables for the *nor* gates and J-K flip-flops.

Nor Gate			J-K Flip-Flop		
Input A	Input B	Out	S	C	Q
Lo	Lo	Hi	Hi	Lo	Hi
Hi	Lo	Lo	Lo	Hi	Lo
Lo	Hi	Lo	Lo	Lo	Reverse
Hi	Hi	Lo	Hi	Hi	No Change

tenth of a volt or so above ground. These two output pins are called "Q" and "$\overline{Q}$," and they are always complementary to each other – when "Q" is high, "$\overline{Q}$" is always low and vice versa. There are four inputs: a reset pin, which brings "Q" to the low state, 'Set," "Clear," and "Toggle." The flip-flop changes state only following a *fast* negative-going pulse on the "Toggle" pin. Which state is entered after a "toggle" pulse depends on the voltages on Set and Clear. (See Table 1.) If more information on this subject is required, see References.

Four flip-flops can most easily be made to count to 16, but for our purposes, we want these to count to only 10. The arrangement used here is called the Modulo -ten minimum-hardware circuit, and is commonly used to divide by ten (Fig. 3), but more complex arrangements are usually used in counters for decimal readouts such as nixie tubes. The states of the outputs through a count of ten are found in Table 2.

In this case, the Modulo-ten was the simplest arrangement I could find from a logic standpoint, because I wanted to energize a 7-segment readout. It was also noted that a matrix which switches off the segments, is a lot simpler than one which switches them on. So that is what this circuit does. All of the segments of the tube are "turned on" except when +0.7V or so is

Table 2
"Q" output states in a Modulo-ten circuit, through a count of ten.

	Q1	Q2	Q3	Q4
0	0	0	0	0
1	1	1	0	0
2	0	1	1	0
3	1	1	1	0
4	0	1	0	1
5	1	0	0	1
6	0	0	0	1
7	1	1	0	1
8	0	1	1	1
9	1	0	1	1

present at the base of the shunt resistor for that particular segment, which then effectively grounds that segment. The complete logic diagram for each digit is found in Fig. 4.

The gates used are *nor* gates; the output of these gates will always be *low* except when *all* inputs are low; then it will be *high* (Table 1). There are also three diode gates used, which simplifies the circuit (this translates "cheaper") considerably. The 2700Ω resistor at the output of one of the gates, slightly increases the voltage output, which otherwise did not reliably energize the "B" and 'G" transistors, because of the additional voltage drop through the series diodes. These are used on the underside of the board, 1/10th watt resistors are a convenient size here. (For placement, see photograph.) You may know that the MC792P has a higher output, voltage-wise, but do not use it! The MC792P would also load the flip-flops much too heavily for this application.

Construction

The circuit board is etched on both sides, and care is indicated to assure that the two

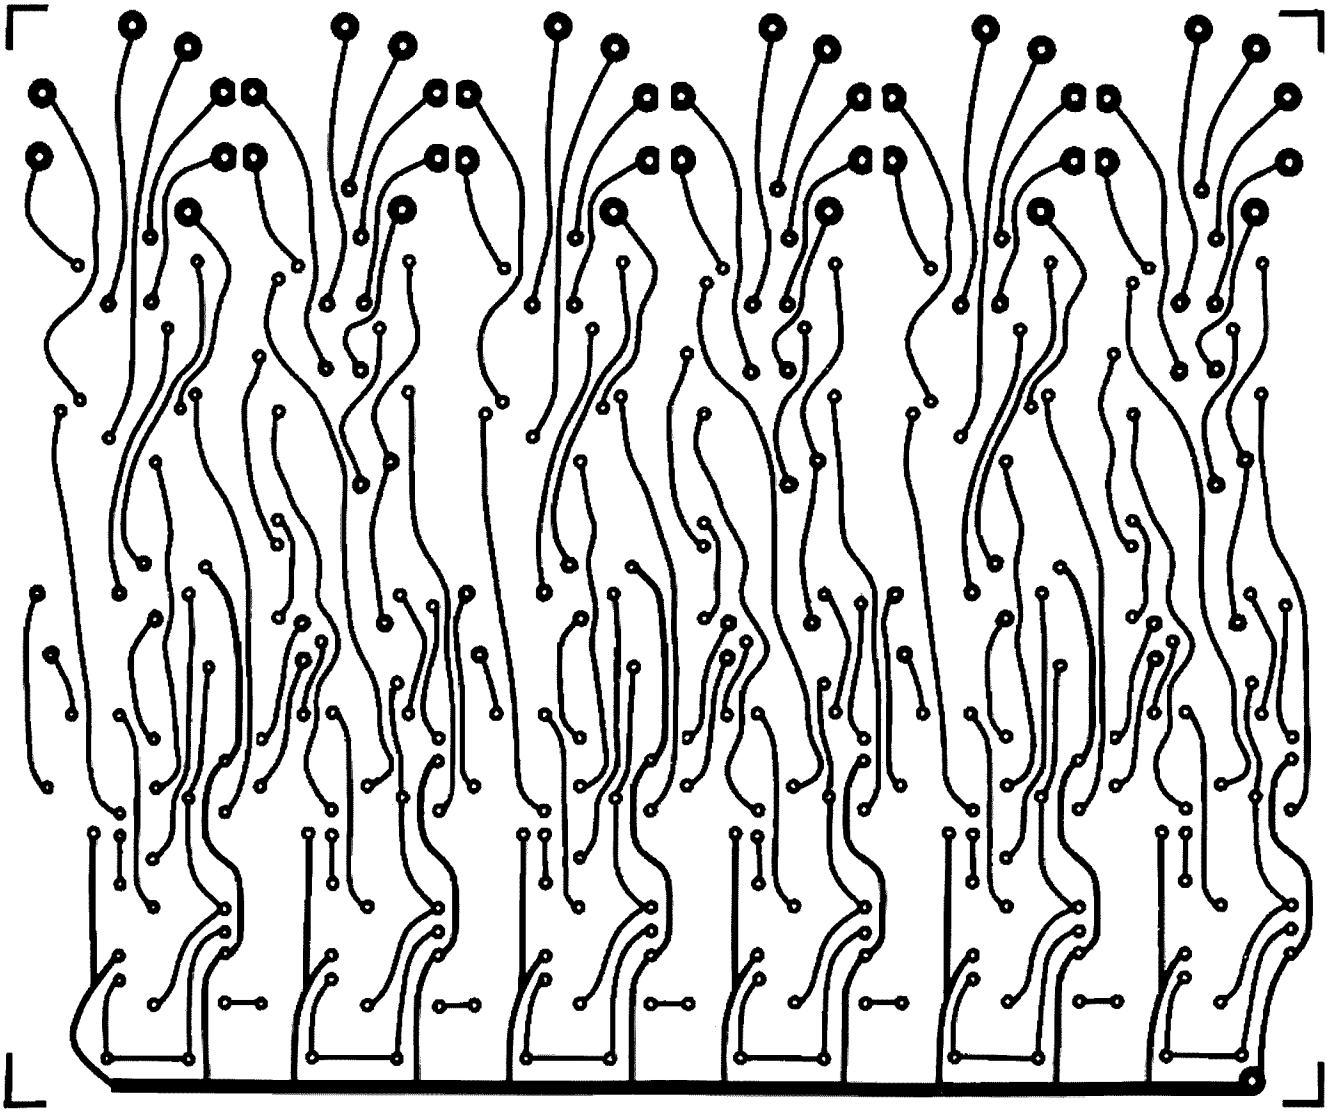

Fig. 5. Component side of the circuit board, full-size.

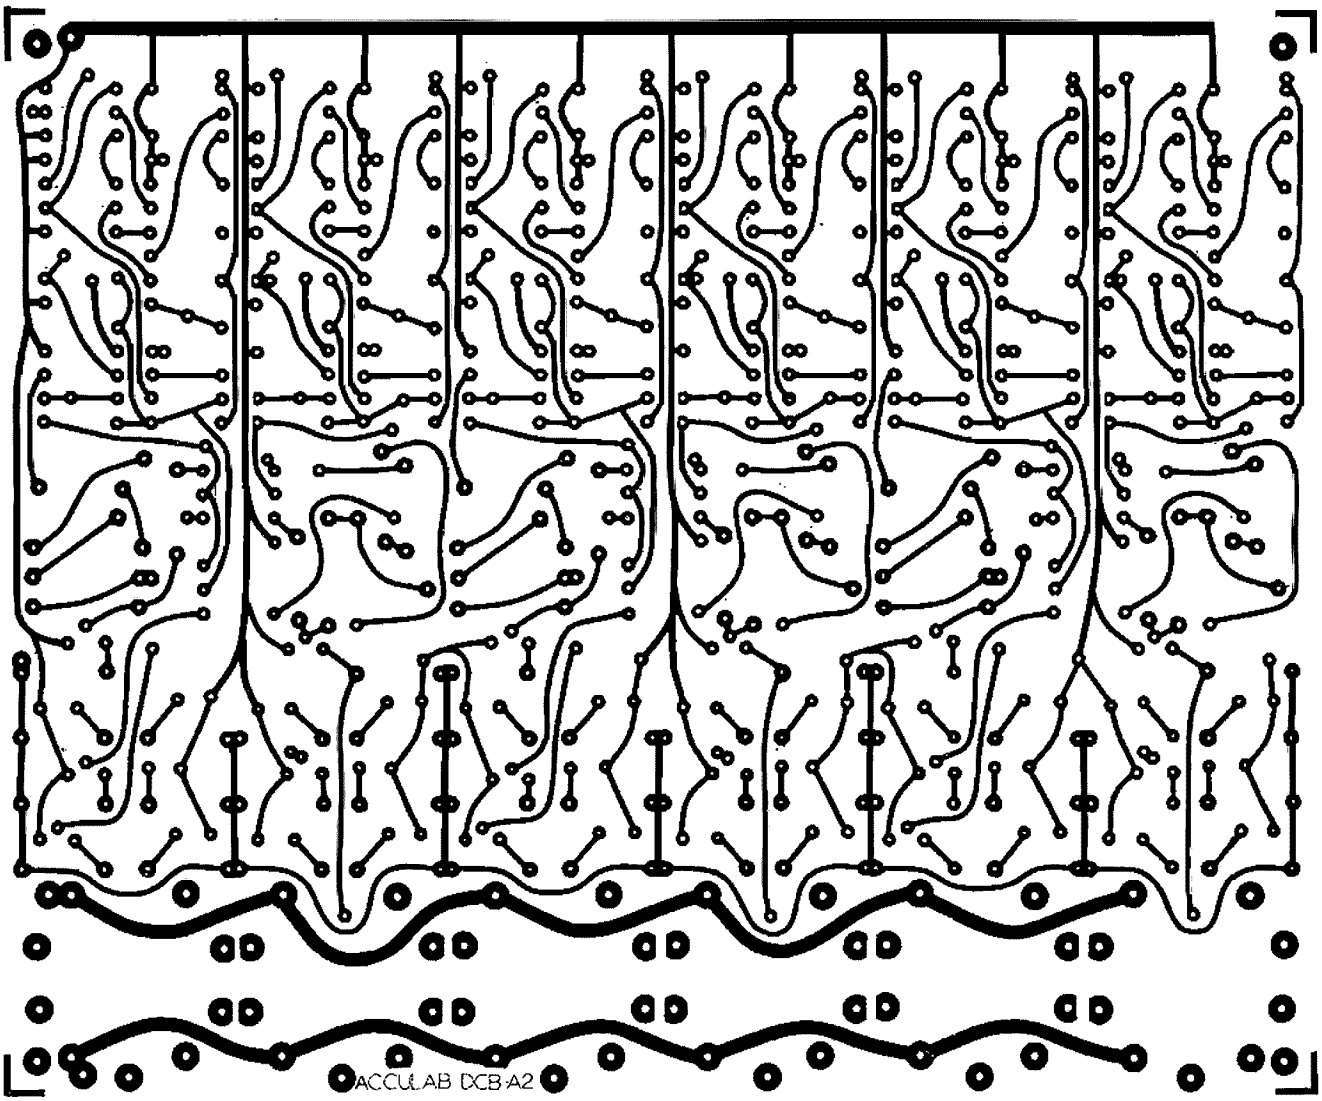
sides are properly matched. I built a jig for this purpose out of 2 7 x 7 in. pieces of 1/8 in. Lucite. All four corners of the Lucite are drilled with the two sheets clamped together. Tape the two negatives to the adjacent sides of the Lucite so that the negatives match properly with the two sheets of Lucite bolted together. Then the sensitized board can be clamped between the two negatives and exposed with assurance that the holes will match up once the board is etched.

It is also possible to etch the board one side at a time. For this method, only one side is etched at first with the other side protected from the etching solution. Then several pilot holes are drilled in the edges of the board. The second negative is then placed on the other side of the board and made to line up with the pilot holes for the second exposure. This method would probably be satisfactory only when you are equipped to use spray photo-resist. However, a pre-sensitized board, coated on both sides, would be very hard to expose, etch, and drill without damaging the sensitive emulsion on the second side of the board. It can be done very easily if you are properly equipped, but be sure to cut the burrs from drilling off the second side of the board before coating and etching, as the burrs pick up an extra collar of resist which gets in the way, and they also tend to scratch up the negative.

Once the board is etched, the holes are drilled. It is probably possible to this with with a ¼ in. electric drill, with extreme care, but a drill press is strongly recommended if you can possibly get access to one. I used a No. 72 drill for the integrated circuits, transistors, and diodes, a No. 60 drill for the resistors, and a 1/16 in. drill for the tube sockets. If you are using fiber glass board, be



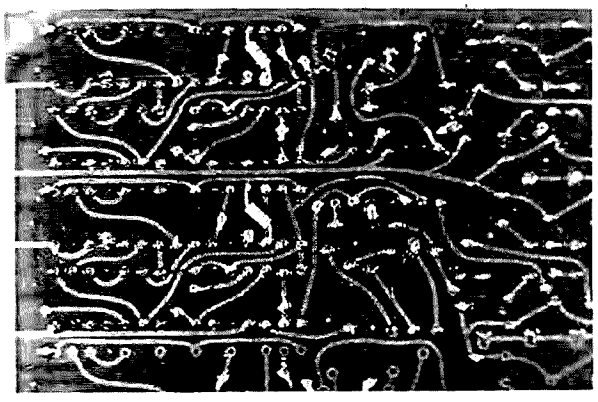


Fig. 6. Second side of circuit board, full-size.

sure the drills are sharp, because I found that a drill which is dull creates much heat which swells the fiber glass, and this can pop the foil terminals right off the board. Fiber glass also dulls the drill bits much more quickly, too, and there are something over 840 holes to be drilled in this board! The drill sizes specified are not sacred, but anything much bigger may just drill the terminals right out of existence, as they are necessarily small.

Once the board is etched and drilled, the next step is to install the jumper wires. Most of these are for power supply or ground connections, or for reset lines to the flip-flops. There are also a number of through-wires to bring current through the board from one side to the other. I used 22-gage wire for this.

Now you can begin installing the actual components. Note that the component side of the board contains the conductors to most of the tube pins. The other side carries the label. It is wise to install one tube socket, then a pair of load resistors (10K) next to the socket, then the first pair of transistors. Note that some of the connections must be soldered on *both* sides of the board.

Once the first two transistors are installed, it is wise to put +18V between the B+ terminal and ground, to be sure that these transistors will hold this voltage satisfactorily without breaking down. Then put the same voltage, through a 22K resistor, or so, between the bases of the transistors and ground, while measuring the collector voltage, to be sure that it will ground the anode of the tube properly. It is best to test these in pairs as you install them, as it is a lot more trouble to get to them once some of the others are in place. Once you are sure that a pair of transistors works, then go on

Arrangement of 1/10th watt, 2700Ω resistors under the board

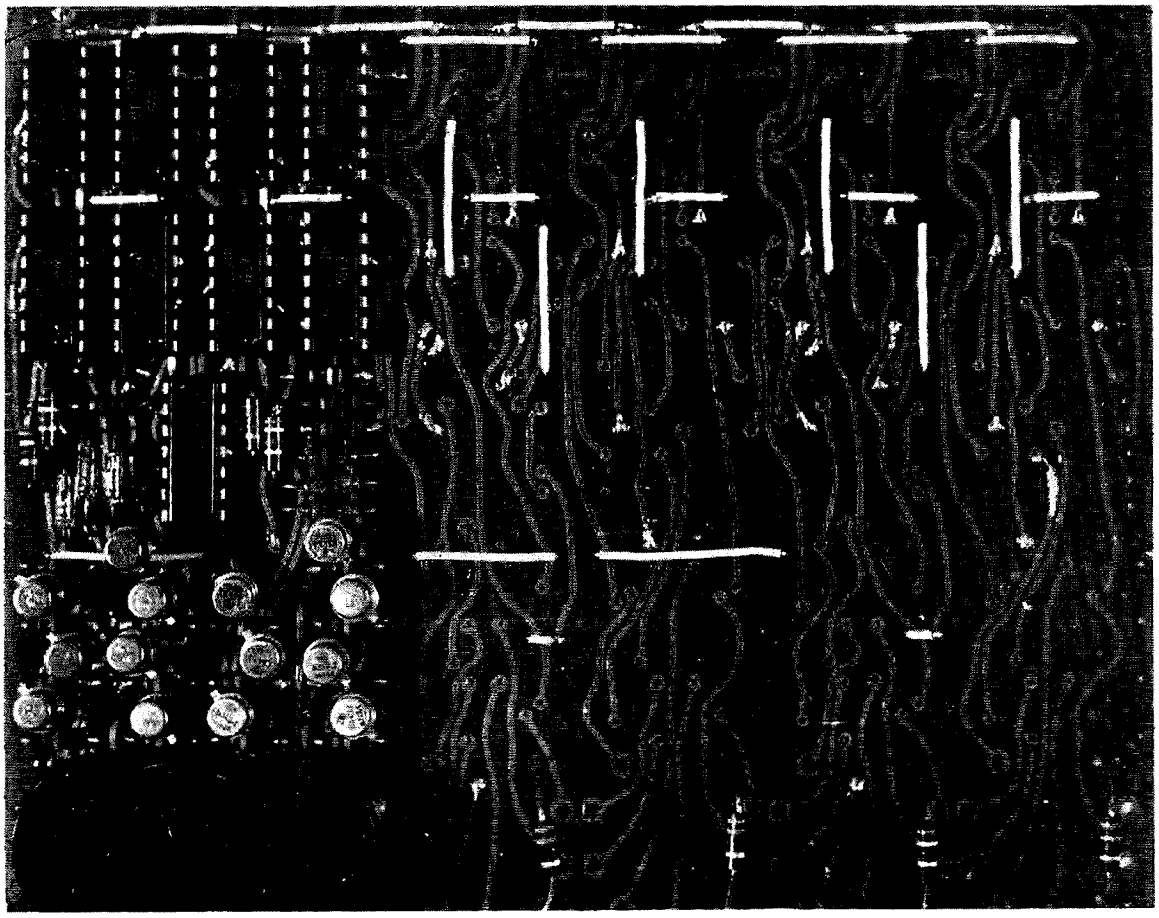
to the next pair of load resistors and then the next pair of transistors. Then be sure to check all of the solder joints and be sure you haven't miss d one or more on the component side, and be sure there are no solder bridges, which will be harder to eliminate later on.

After the transistors, the next step must be installation of the first IC, the MC717P. It is very wise to first tin the foil terminals for the IC's, at least on the component side of the board, as there is no way to heat-sink these soldering operations, and this greatly reduces the amount of heat exposure to the IC. It will be almost impossible to get to some of these joints above the board, once the resistors and diodes are in place. Note that the MC717P's are the only IC's which have the notch and dimple on the package, positioned *away* from the tube sockets – all the others have the notch and dimple on the end *toward* the tube sockets.

Next the diodes can be installed. The cathode ends of the diodes, usually marked with colored bands, are always on the side toward the conductor leading to the bases of the transistors. On the digits where the diodes are horizontally arranged, this is the end *toward* the tube sockets. On the digits where the diodes are vertically arranged, this is the end *toward* the MC717P, except the center diode is reversed.

Now the other resistors can be installed. Note that two of these are 390Ω resistors, these lead from outputs Q1 and Gate 7. The rest are 1500Ω.

Following this, install the two MC793P's and two MC790P's. Be sure the notch and dimple on the cases are on the end *toward* the tube sockets. Be sure to tin the foil terminals on the component side, for these IC's, also, to mimimize the heat loads they have to take in soldering.



Next, solder the 1/10W, 2700Ω resistor, on the underside of the board, between the output of Gate 7 and the adjacent pin 11 of IC4. This increases the voltage output of this one gate, as described above.

Testing the Counter

I found it convenient to test each digit as wiring was completed on it. The filaments of the tube require 1.6V. One side of the filament must be connected to the common ground. Connect +18V to B+. Without the +3.6V supply being connected, all the segments of the tube should light up. When the +3.6V supply is connected, the pattern may not represent any number, but should become "0" when +3.6V is connected to the reset line. Any of the segments which do not light up at this point, probably represent a missed solder joint or jumper wire, or a shorted transistor. A segment lighting up when it shouldn't might mean a missed solder joint somewhere between one of the gates and the base of a transistor, an open diode, or a faulty transistor. Since these are all dc circuits, these should be easy to trouble-shoot with a voltmeter.

To test the counting operation, it is very convenient to have a source of negative-going pulses. I used the clock which I had built for this counter, which will be described in another article. It furnishes pulses from 100 kHz to one per second. One pulse per second makes the operation of all the circuits very easy to follow, and you can stop the input pulses whenever you note a problem, and then check the states of all the outputs with a voltmeter, referring to Table 2.

Lacking a convenient source of pulses, you can check the operation of the flip-flops by feeding a sine-wave signal of a volt or so peak-to-peak, and above 100 kHz, into the input of FF1, and checking the Q output of FF4 with an oscilloscope to be sure the circuit is dividing by ten. If it is, very few

The counter with the first two digits completed. Jumper wires are in place. Note a 10K load resistor next to each driver transistor. These are merely to limit the current through the transistor when turned on. The resistors with the light stripes are the 390Ω.

things could be wrong with IC1 and IC2. The output of each of the gates should be near +1V, when all of its inputs are grounded, and it will not harm the outputs of the flip-flops if they are grounded.

If the +3.6V power supply is not well filtered, pulses from the power supply could possibly leak through into the counting circuitry and foul up the counting process, or make the flip-flops count without any input signal. Three nickel-cadmium "D" cells in series, make an excellent power supply for 30 minutes or so, if you suspect this possibility. In fact, the counter could easily be powered entirely by batteries.

With all six digits counting, the board requires 3.6V at about 500 mA, 1.6V at about 270 mA, and 18V with a current demand which fluctuates widely but peaks at about 60 mA with a readout of "111111," and reaches a minimum of about 8 mA, with a readout of "888888."

If you have had a little experience in building solid-state devices and are willing to use care in soldering, this counter should go together with no trouble. The counting logic is extremely simple and the digital readout logic is easy to understand. If you will make sure that you understand the operation of these basic digital circuits before beginning construction it should be a pleasure for you, as it was for me.

REPEAT IT -- THE LONG WAY

Let me be quick to say that this is not just another of the many fine articles on FM or repeaters, as the title may suggest. The availability and low cost of used commercial FM equipment in recent years has brought many hams into the use of channel-type and repeater communications. I would like to introduce you to what I feel might produce results far beyond the present dream of linking the four corners of the U.S. via FM repeaters. Moonbounce is the name of our game, via a system of repeaters!

Two years ago, when our project started, a group of five local hams were already operational on the VHF bands. Many hams had preceeded us there, and many were already quite active on moonbounce projects. Many of these efforts made fine reading, but how many of us have an Areceibo size hole in our back yards, or finances for a large dish antenna on our own?

Since the group is all involved in the electronics field, the idea of researching past articles and ideas came quite naturally. In our jobs, this is done to get a starting point as well as to avoid future patent difficulties. That's when our first problems began. Articles were found, to be sure, but none contained current EME activity, amateur calls, or frequencies in use. What was worse, no column seemed to exist dealing specifically with this area. Since *73* Magazine, with Wayne Green, W2NDS/1 at the helm, seemed to contain more VHF construction articles per column inch than the others we checked, a quick letter to Wayne seemed in order. True to form, he has even offered space for such a column pending enough interest (write Wayne, c/o 73 Magazine) and, of course, finding someone in the know willing to write it. Good magazines are always looking for good articles and good column writers, so try to help if you can. Please contribute where and when you can.

Since this is an "idea" article, I want to present it in a block diagram, no math, no construction format. I will present future articles dealing with specifics. Our idea is a system of many sub-systems which I will divide and discuss independently.

The Links

Most of us don't have the back yard room for a large antenna for moonbounce. Because I do, we had the biggest problem licked. Look around your area, city, club or group. Surely one member has the room, or like FM repeaters, it is for rent inexpensively just outside of town. Remember, no mountaintops are required. 5000 isn't much over a moonbounce path! So look for a low noise area if you can find one. Organize, but don't overdo it, as you will scare off the guy that doesn't feel he has anything to contribute. A club, or even just a group of amateurs meeting together with a common purpose is fine. Communicate! This is where the first building block takes shape. Everyone is busy and can't always make meetings, but we all get on the air. At least this way the XYL knows you are home. Choose a locally *unused* FM spot on 144–220–420 MHz, and get equipment on. I caution you now, please, don't use existing FM channels except to initially keep in touch no matter how tempting. I chose the 420 MHz band, since local activity there is almost non-existent, but this is a good chance to get active on the 220 MHz band as there have been some recent conversion articles for 2m FM gear. Due to the very inexpensive equipment and antenna size, the 420 MHz band may still be your best choice. This usually means building your own 110 VAX power supply for existing mobile type equipment. By all means coordinate, and try to buy the same type of gear so the power supplies, crystals, and other accessories will or can be alike and thus save many headaches. This also can lower the price by group purchasing. Once the equipment is on, you have a "meeting place," any day or hour, and someone else to help you iron out problems. This equipment is not at all lost when moonbounce time comes along. Quite the contrary. It will form the only equipment needed by anyone, except the site chosen for the moonbounce equipment. Plan on adding tone encoding equipment to the control head as you build it in order to be able to control the site from each amateur's home. If the site chosen is in one of the amateur's homes and he is to be present during moonbounce attempts, you don't even need a repeater license.

The Site

The equipment here can be completely a group effort. However, if it is, get the agreement in writing that it is donated to the group effort to avoid future problems and hurt feelings. Most of our site equipment will be my own. Parts and much building help overcome the problem this way. The overall equipment should be "racked," and cabled, and a full set of diagrams drawn. Believe me, this has already saved us much grief. Unless you can work with the equipment daily, and you aren't far enough along to have much gear yet, you would be surprised how much you can forget even if you wired it!

The transmitter should be crystal controlled, preferably using an oven, and CW makes a good inexpensive mode choice. For the purpose of our own experimenting, we will also have NBFM from the beginning, adding SSB as time and finances permit. Build your rack by building blocks, and if you home brew from scratch, add many, many test points brought out to the panel. The blocks will give you a sense of accomplishment as each is added and checked, and the test points allow for fast checks, periodic maintenance, and rapid trouble shooting. By all means build. Why waste a $700 transceiver on a spot frequency job. Get the low level exciter running, and test it unmercifully for local contacts. You may wish to add AM modulation capabilities at this level to increase your number of local contacts. Let it run 24 hours a day, and build it so it will. Use caution concerning fire if the equipment is unattended for long periods. This is why we rack mounted everything (confine it) and temperature monitor all of it (shuts it down). As you add control, identification, and taping functions, allow the exciter to "talk back" on a local 2m link anything sent in on the link. This is exactly what it must do later.

The power amplifier cannot be slighted. Mount it at the EME antenna if at all possible, and go as close to the legal 1 KW as you can muster. One man may have a meter, another a transformer, etc. Anything

less and you may be very marginal. This is one time when you are using the "minimum power to maintain the circuit," per FCC regulations. If you find you need less later, dropping down only buys you nice long tube life and like benefits.

The receiver can be a well overhauled, and in top-notch working order, surplus gear item. This saves money and saves tears if you decide later to modify it extensively. Automatic scanning can be added later for complete remote use. Remember, Uncle Sam pays thousands for these items, so you're not getting junk and you can get a real bargain if you try. The converter/preamp must be top-notch. Here you may have to pool talent or resources or both. You may have to buy one to get on, and later try building from one of the newer MOSFET type articles. This area is totally up to the time, talent, and the funds available within your own group.

I left the best for last, since another article will cover this one in detail. The EME antenna can be as varied as the number of hams actively working moonbounce. If you start with 144–148 MHz, and I suggest you do because of the equipment, stability, and activity, you unfortunately end up with the largest physical size of antenna. However, if you chose carefully as we did, you can later use it for higher frequency work. This is what we did and why.

Our dish will initially be a quasi-parabola, looking at the side like a parabola, and from the front, a rectangle. From the description you can see this is not a readily steerable antenna for a polar mount. It is not. It is driven el-az, or independent elevation and azimuth. If your only interest is moonbounce, by all means stay with polar mount as steering becomes difficult otherwise. We intend satellite work and space shot tracking as well, and thus our decision to suffer the consequences of a complex steering arrangement. Our dish is entirely wood-of-sorts, covered with hardware cloth, and built in 4 ft. by 8 ft. panels for ease of construction and placement. Wood can be very strong and warp resistant if the right types are chosen and it is finished with the proper materials. Multi-element yagis and co-linears are being used, but bear in mind the aluminum cost, single-bandedness, and sheer size of these arrays. The collinears for example are of the 150-plus element type. The size and cost of our dish, the means of mounting and steering it using inexpensive (modified) TV rotators, brings it down to the level of many more amateurs' funds and capabilities.

The Assault

I will present you with the ideas and means we are really using to accomplish our goal – 2m moonbounce. To prove to you that no design work is necessary on your part, many hours of research on the part of the initial members of our groups has been spent compiling the following list of articles that can be directly applied to your efforts. Full credit for these fine articles appears with them, and they are lettered to tie them in with the block diagram. Just to give you an idea of what we did, some are singled out as being our choices.

K. EME to LINK Interface (same as Section C).

L. Link Transmitter (Motorola T44AAV — Transmitter TU204).

1. Same as B-1.
2. 50W on 420 Megacycles (More power for link if needed), WØWGZ, *CQ* April 1952, p. 13.

M This section covers the entire station as a whole.

1. Tracking The Moon-In Simple English, W3SDZ, *QST* January 1965, p. 37.
2. Moonbounce Problem, 28 Mc. and Up, W6VGL, *QST* September 1963, p. 20.
3. Lunar Nomograph, WA6NCT, *Ham Radio* October 1970, p. 28.
4. Appearance of the Moon at Radio Frequencies, W2TTV, *QST* May 1961, p. 21.
5. Mechanisms of Space Communications, K2QBW, *QST* December 1961, p. 22.
6. How High The Moon, WAØIQN, *QST* July 1965, p. 55.

Put this kind of line up together, using the articles for a guide, and a respectable moonbounce station will result. For the obvious cost reason, many amateurs have never tried. I hope it will now be possible for you to share costs and rewards by using a shared system. It should be monitored more, and used more, and this yields more activity.

I would like to acknowledge the assistance (both physical and research) of the following members of our group: K9LNX, K9MKU, K9RYK, WA9BHF, and WA9DTM. Further thanks to all the active moonbounce stations that have helpfully replied to my mailed inquiries. More information can be obtained by stating your question as clearly as possible and sending a SASE to Echo Amateur Radio Group, c/o R.R. 5, Box 39, Noblesville IN 46060.

INTERESTED IN ANTENNAS?

Table-top the Main Features . . . Indoors

Try reflector and director lengths, spacings, numbers, combining yagis, extended-expanded collinears, ¼ wave, ½ wave, and two-half waves in phase for 160 and 80 meters right inside your shack!

Complete construction details for an antenna test set of 432 MHz. Easy-to-build units; a 432 MHz oscillator and a tuned detector are detailed for you. These *rf* units may be used later to build a complete hand-carried solid state portable station on 432, with superhet receiver. This station is described in *73 Magazine* in the article "The 432'er Solid State."

With care and using a small iron you can also test spare or surplus VHF or UHF diodes and transistors lying around the shack, by substituting them in these *rf* sets.

Oscillator Construction.

Figure 1 is the oscillator schematic. A UHF transistor, like a 918 or RCA 2N3600, is used in a grounded-base circuit, which makes it a good oscillator right away. The copper strap over copper-clad baseboard results in quite a high-Q circuit, is easy to couple out of, and tunes over a lot more than just the 420 to 450 MHz amateur band, unless you wish to pad it down and/or remove plates from the Johnson type M capacitor. An output coupling capacitor is provided for better adjustment to the 50 ohm output cable.

Figure 2 is a top view, and Fig. 3 is the side view. This unit is similar to the one in the "432'er, Solid State" article in *73 Magazine,* making it easy to transfer it into the complete rig described there later on, if you wish to do so. There is a slight difference in the dc bias network because in antenna test work a lot (like 100 milliwatts!) of power is desirable, while for local oscillator service in the superhet receiver, lower harmonic content and less power are wanted.

Tuned Detector Unit.

The schematic is in Fig. 4, the top view is Fig. 5, and Fig. 6 shows the side view. The detector diode unit is also similar to the "432'er" mixer unit, except that the *if* coil is not installed and the dc output is brought out of the *if* jack. Be sure to leave space for the *if* coil if you want to use this detector later on as a mixer.

Operating the Antenna Test Sets.

After building the *rf* units, set up two card tables, one for the oscillator and transmitting antenna test units, the other for the receiver antenna and tuned detector, as in block diagram.

Next step. Go over to the other card table and set up the tuned detector. This is very convenient for indoor work, as you will see. For checking directivity, good gain measurements. Getting away from the "near field" are some of the reasons for the two tables.

The diode detector needs no battery but you will need a good meter, which should be a 50 mA unit for best sensitivity. You can use a heavier meter, but it will just not be as

sensitive, and will require the two tables to be closer together.

Plug the antenna cable into the detector jack No. 1, and the other end into the dipole jack. Tune the detector to 432, and you should then have current showing, if the antennas are only a few feet apart to start.

Important Notice!

As soon as possible after positioning and tuning up a dipole, reflector, and director, set up at least a three-element beam to use as the receiving antenna for the test meter, and point it at the transmitter antenna under design and test.

A simple three-element unit for 432 is shown in Fig. 7, as a sample of what can be done for the purpose of getting started. You may well tune up a *better* one which you can then scale up to six meters, ten, or whatever band you wish. Nothing prevents you from using as many elements as you want to tune up! Three elements are handy for indoor work.

The use of a three-element (at least) beam eliminates a great deal of nuisance reflection, including *yourself* as you move about. The stability of the detector meter when two beams are pointed at each other is remarkable. Such an antenna, for test purposes, can be used for reception of energy from any other type of antenna you may wish to try.

Cable Matching

You will notice a trimmer capacity on the radiator. This is an important little item, as you will see when you adjust it. It is part of the gamma match, and quite necessary (as you can find out by shorting it out). In general, use more capacity for lower impedance, with closer spacing. Use quite a bit less for the dipole alone.

I use a long-handled fiberglass screwdriver and adjust the capacitor from *in back* of the reflector, readjusting the spacing and oscillator tuning each time. This can be important. You also can vary the *length* of the gamma match and its *spacing* from the radiator.

When you get that antenna "matched to space," which is exactly what you're after, you'll see the difference.

Of course you can try other types of feed too. An intriguing type which can give you a perfect match to a 50 ohm cable is shown in Fig. 8. I "invented" this style while with a large antenna project on Commonwealth Avenue in Boston about 1957, and it won out over a "conventional" dipole with stubs and all.

Cable Length

This is also important to check. The only time cable length is *not* important is when you have a perfect match, and usually that is never! Just try it. If you can add an eighth wave or a quarter wave and not change results on the antenna, that is an absolute check on vswr.

Radiators, Reflectors, and Directors

The results should open your eyes. For example, let's see you try to tune up a three-element job with close spacing, like a tenth-wave!

Get yourself an extra roll of aluminum clothesline and some more dowel wood at the hardware store and have *more* fun. Cut reflectors, 5, 6, 8, 10, and 15% *longer* than a half-wave in free space, and see what happens. Let yourself go!

Get still more aluminum and try 5, 6, 8, 10, and 15% *less* length for the directors. You may have *more* surprises. I have only described material for two three-element beams, to illustrate the basic principles and tuneup of reflectors and directors, but don't let that stop you from adding as many more elements as you wish to try.

My biggest so far was the 36-foot-long job, with 16 wide-spaced elements on two meters that I used on mountain tops. Incidentally, each director you add to the beam should have a length of a little less than the previous one, till you get about half a dozen tuned up and placed.

Just a word about many-section yagis. After the "launching section" is tuned up, comprising those first half-dozen or so, the rest of the directors *can* be the same length. I have never found it possible so far, however, to sue the same *spacing* for numbers six to sixteen. You *can* do this, like some of the commercial lads, but I have not found this to give maximum gain which is what I've always been looking for, personally. You will be able to check this yourself with this antenna setup. You will

also see that every director you add will *increase* your gain, even the *last* one you add.

Sheet Reflectors

If you want to pursue this matter further, get some aluminum sheet at the hardware store. Better yet, for the dollars involved, get some aluminum flashing and try various sizes and spacings for sheet reflectors. Take a large piece of sheet, such as 18 x 18 inches (not critical) and mount it on a movable dowel like the other reflectors, and watch that meter. I have always found that the tuned reflector (some 10% greater length than the radiator) has better gain than the sheet reflector. Also check the front-to-back ratio with the sheet reflector; it could be better.

Two Yagis Together

As you see, this can go on and on. Don't say I didn't warn you. Just try for fun adding two yagis together. Or better, try adding two dipoles first. You will soon see that even two dipoles have to be spaced greater than a half wave for best performance. This is because the capture area of even a dipole extends out beyond the half wavelength.

It wasn't so long ago that I used to manufacture and sell collinear arrays, as owner of the UHF Resonator Co., Rye, N. Y. These were spaced only a half wave and did not have the gain they should have had. This was because a "time-honored" method of feeding a collinear beam in all the books shows the half wave line as a matching section, which precludes anything *greater* than half-wave spacing.

The day came, however, after reading about capture area for the umpteenth time, that I felt I should check this item out for the two-element yagis that compose most collinear arrays. This is a large part of the deal. The collinear, as usually made up, has *reflectors* as well as dipoles so that you are really combining two yagis together with every two sections of the collinear. And, two yagis *must* be spaced much wider than the half wave if you do not want the capture areas to interfere. When they do, you are just putting up more aluminum than you are using. Check it out for yourself.

Match up a good radiator and reflector, then make a second identical one and check it out for similar gain and directivity. Then connect both together as a four-element array composed of two yagis, using equal length cables for phase maintenance. See Fig. 9. You should join the cables close to the oscillator, or use a quarter-wave matching section of 35 ohm cable. This is because joining two 50 ohm cables makes a 25 ohm impedance at the joint.

Start with the reflectors almost touching and the yagis side by side, which is the way they are in a collinear array. Fig. 9 shows them already "expanded." When you get them set up, watch the meter as you pull them apart – what a revelation that was when I first did it.

80 and 160m Beams

Figure 10 shows a setup on 432 MHz for checking end-feeding of a half-wave antenna for 80 and 160 meters. If you have the territory, two of these, known as two half waves in phase, makes a very powerful antenna for 80 or 160 meters. This is shown in Fig. 11. Note the low capacity of the end fed coupling units. This is important, because you should *not* load a half-wave antenna directly onto a tuned circuit, and expect much tuning.

Marconi Types and Angle of Radiation

Put a piece of that aluminum flashing on the table, add a little wet earth (maybe not in the living room) and add a little salt if your shack is near the ocean. Now you can check verticals against ground, and ground effect of high gain beams, which shouldn't be noticeable if your beam is putting 90% of its energy out in front, which it must do to have some 10 dB gain.

With a little ingenuity, wooden dowels, and still more aluminum (or maybe you can use smaller copper wire for these tests), you can check scale model quads, halos, stacked halos, hula hoops, big wheels and almost anything you can dream up. Of course you're now getting near the professional style of antenna scaling. But maybe that isn't too bad.

Gain and Front-to-Back Measurements

There is a positive way of checking the

Symposium continued from page 3

FM SYMPOSIUM SEPTEMBER 24TH

The release of the repeater regulations by the FCC with an October 9th deadline for comments demanded some fast footwork by repeater groups if they were going to be able to intelligently respond to the situation.

After waiting for several days for the Northeast Repeater Association to get into gear and come up with a meeting, and after it became obvious that this group would not get together before their annual meeting on October 7th, far too late for repeater groups to return home and organize a response to the FCC order, 73 Magazine hurriedly set up a meeting place in Waltham (Mass.) and announced it in the Repeater Bulletin.

The Bulletin, by the way, was in the mail to its subscribers on Monday September 11th with the full text of the new regulations which were released on Friday the 8th! The order had been tentatively released about ten days earlier, but it took some time to actually get printed and mailed from the FCC.

The Waltham symposium drew representatives from nearly 30 repeater groups, not counting multiple representation by individuals, some of which claimed to represent up to eight repeaters. Despite repeated attempts of NRA representatives to interfere, the meeting went very well and its objectives were met.

220 MHZ BAND PLAN

The frequency coordinating committee of K1KEC, K4GGI/1 and F2BO/W1 were all present and had come to the meeting prepared to explain their plan for the modified 220 MHz band. This committee has been working together for several months organizing the New England repeater frequencies – with spectacular success and cooperation. It perhaps should be explained that this committee pre-dated the NRA and agreed to work with NRA when that group was formed since it seemed beneficial to get together with them

The committee did not expect to find NRA officers demanding that they keep their work a secret from New England repeater groups in order to give more prestige and power to NRA, but this is just what happened. NRA said no, you cannot be part of NRA if you do not do what we say – and we say you cannot present your 220 MHz plan at Waltham, but must hold it until October 7th for the NRA meeting.

When this fact became known to the Waltham symposium repeater representatives, their anger and irritation with the high-handed actions of NRA grew noticeably.

The plan was presented anyway – and adopted by the representatives. It consisted of using a 1600 kHz split with repeater input on the low end and output high, starting at 224.98 and working down every 40 kHz. This leaves a few channels in the middle to avert repeater outputs getting into other repeater inputs. Simplex 223.50. Agreed also to leave 222.0 to 222.3 open for weak signal work for the time being. Late word has it that the California Amateur Relay Council has approved the same plan – and NRA is expected to put its stamp of approval on it.

VETO REGULATIONS

The group discussed the new regulations in depth. The pros and cons of the entire order were considered and the vote was taken on whether the group preferred to go with the new regulations, hoping to change them later, or to stop everything and continue with the regulations (or lack of them) the way they were. The vote was, with one exception, opposed to adopting the new regulations.

The complete report on the Waltham symposium is in the Repeater Bulletin ($2 per year as yet).

. . .Wayne

actual gain and front-to-back ratio of beams which will not cost you a cent. This method is simply the distance method. Twice the distance (with equal power showing on the meter of the detector) is a power gain of four times. How could it be simpler than that? A gain of 3.33 in distance equals 10 dB in power. This of course is in free space. If you really match up your *dipole* radiator for maximum output and find it registers 50 on the meter at ten feet, then substitute your new tuned-up beam and find you can go out to one hundred feet with the receiver array and still have it register 50, you've got a 20 dB beam! I should warn you though that *that* amount of gain takes a beam of about six wavelengths square, which, even on two meters, is some 36 feet *on a side.*

There can also be some ground effect, so you should average it out by raising and lowering one or both of the beams up and down to check.

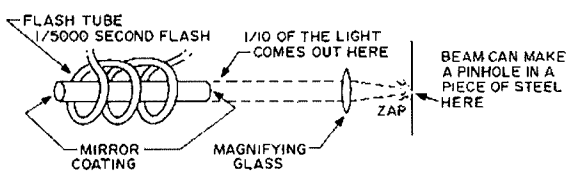
The front-to-back-ratio check is equally easy. With the main signal on, go around to the back of the beam with the detector, meter, and receiving beam in your hand. Adjust your distance in back of the transmitting beam for a low reading on the detector. This is probably what you'll get anyway. Then go around in front. The difference in distance is the front-to-back ratio, naturally. Don't forget, for the power ratio you have to square the *distance.* Good luck on that one.

Remember the law on antennas, "Gain is equal to directivity." Under certain conditions, not generally encountered nor desirable, you can get directivity without a corresponding gain, but never gain without directivity.

It is generally considered that a beam tuned for maximum forward gain does not at the same time have a maximum front-to-back ratio. This is more evident with three-element beams than with high-gain jobs. You can check yourself with these test sets, plus a little more aluminum, wood, and time.

That's about it, so hope you have as much fun as I do with these kind of tests. It seems that every time I work with antennas, even after some 44 years of it, there are still new things to be learned. . . . K1CLL

W. Edmund Hood W2FEZ



ALL ABOUT LASERS

The atomic spy stood on the shores of Jupiter's Red Lake and focused his radar binoculars on the enemy ship 1100 miles away. Then with savage sneer he drew his laser pistol. There was a resounding "ZAP" and a blinding flash. The ship was instantly vaporized.

This is the picture most junior operators get when they hear the word laser. Well kids, I hate to spoil your dreams, but it just isn't so. There isn t a laser in the world that could destroy even a toy ship. In fact, the average laser doesn't generate as much power as a 22 calibre bullet. Believe me, I know. I've built 'em. The big thing about a laser isn't how much power it generates, but how it's concentrated.

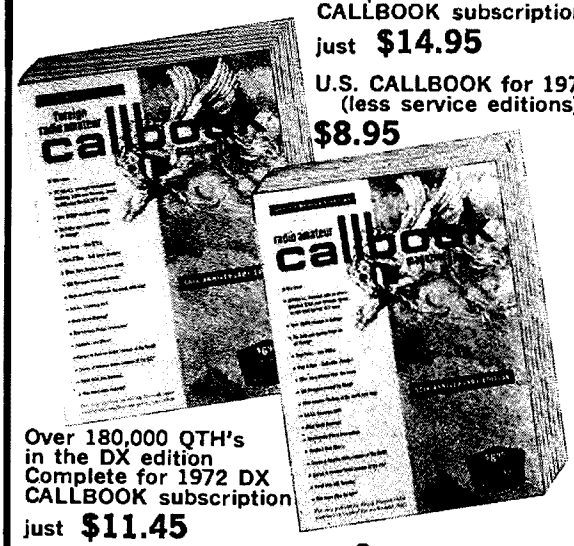
The word laser comes from the initials of the words, "Light Amplification Stimulated by Electromagentic Radiation." This means that one kind of energy is pumped into the laser, and another kind comes out. It doesn't "create" energy.

The heart of the most popular kind of a laser is a solid ruby about the size of a cigarette. (I've seen them much larger, but this is average.) Each end is plated so that it will reflect light. The plating of one end is thin enough so that it will let out about one tenth of the light and reflect the rest. The ruby is surrounded by an electronic flash lamp similar to those used by photographers, only much more powerful. The power supply for this flash lamp can weigh several hundred pounds. (That's why they haven't built many laser pistols.)

RUBY LASER

When this flash lamp goes off, nearly all the light is forced into the ruby by a system of mirrors. This starts a chain reaction in the ruby which generates more light. The light generated inside the ruby is very pure – that is, it's only one color, while the flashlamps were, like most lamps, a mixture of many colors. The light within the ruby cannot get out through the sides, so it tries to come out the ends. The reflective coatings on the ends causes it to bounce back and forth through the ruby. Each time it passes through it makes the ruby generate more, until it gets so powerful that it shoots out through the thinner reflector. All this takes place within a few millionths of a second.

When the light comes out of a laser, it doesn't spread out as the light from a flashlight would. If the beam is ¼ in. wide as it leaves the ruby, it will still be ¼ in. wide a mile away. This is what makes a laser beam so valuable. You don't lose any power at all. An ordinary light would spread out and much of the power would be lost, but a laser beam sends all the light where you want it. And, if you could see the light waves, you would see that they were all the same wavelength, and all vibrating in the same direction, or as the scientists say, they are all *polarized* in the same direction. This way, no matter how far you send the beam, you can recover all the energy at the other end.



Anybody knows if you take a magnifying glass and focus the sun's rays into one tiny spot, they will burn a hole through a piece of paper. Now sunlight contains many colors, and each color will focus differently from the rest. When you try to focus sunlight with a magnifying glass, the best you can do is come close for all but one color. Not so with a laser beam. Since it contains only one color to begin with, you

can get all the energy into one tiny point. When you gather it all together, a little bit will go a long way. In fact, a flash that lasts only 1/1000th of a second will, if concentrated by a magnifying glass, burn a hole through a piece of steel such as a razor blade. However it would be very impractical to use a laser beam to make a hole in an enemy warship. You would have to have somebody near the ship to hold the magnifying glass, and the enemy might not like it.

Seriously, though, while you can't sink the Queen Mary, or vaporize Newington CT with a laser, it still can be used to do a lot of good. For instance, hospitals use them to weld the tissue on the inside of an injured eye. Before lasers were discovered, that was an impossible operation.

So far I have only discussed the ruby laser. There are several other kinds. For instance, a gas laser, made of a glass tube something similar to a neon light, is one of the most promising kinds. The glass tube contains a neon-helium mixture and is excited by a radio transmitter. The laser beam is steady rather than a quick flash, and if the beam is modulated messages can be sent with it. A communications laser can be beamed exactly and sent to only the receiver it is meant for. Hams have long ago communicated with laser beams over hundreds of miles. One type generates a microwave signal instead of visible llight. This is called a Maser.

GAS MASER

Eventually,I suppose,somebody will figure out a way to make a destructive weapon from a laser. Meanwhile, without getting fantastic, this fascinating beam of light holds a lot of promise, and beckons invitingly from the doorway of an amazing space-age world of incredible technology.

Here is a quick-switch antenna patchbox, with built-in transmatch and dummy load.

Put 'Em All In One Box

o you already have half a dozen different transmitters, a like number of antennas, plus a transmatch, dummy-load and rf-ammeter?

OK, OK, but how do you connect up this lot, eh? My bet is with odd lengths of coax, alligator clips, or even, like me, by twisting together odd bits of flex, kept in the sockets with matchsticks . . . right the first time?

Of course this is all in the true amateur spirit, but is really the quickest way to get the wires crossed – literally – and maybe sustain a nasty rf burn (and don't they take a long while to heal up?). And it can be just as painful to the pocket when you inadvertently put things to the "smoke test" . . . such very expensive smoke!

All such dangers can be eliminated by knocking together this nifty little unit which combines a switched antenna patchbox, transmatch, dummy-load, and rf-ammeter.

You'll wonder how you ever did without it when you find you can instantaneously switch *any* of your transmitters to the dummy load or any antenna. And switch so quickly that a *true* comparison can be made between different antennas – both on reception and transmission. Valuable time is also saved in contest working.

It will be noted at once that this unit embodies only the best ergosonic principles! The various inputs from the transmitters are on the left hand side, right next to the switches so as to keep the leads short. The meter is in the center, the tuning knob is on the right, and output sockets to various antennas are on the right hand side of the cabinet. To keep them cool, the dummy-loads are on top (actually, there's no room inside), while the high-Z output for the

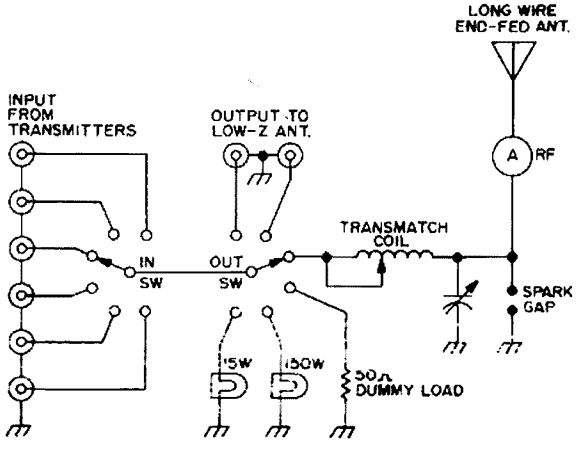

Fig. 1. Inputs from the various station transmitters enter on the left and are switched either straight-through to low-Z antenna, or alternately to the dummy-load, resistance, a load-bulb, or the transmatch "rotary-roller" tuner feeding the long-wire antenna.

end-fed longwire is way behind the capacitor, where it is more or less safe from straying fingers.

The basic requirement of this particular magic box is the Coil Aerial Tuning No. 2A for the Canadian Marconi No. 52 transmitter, currently available on the surplus market. This consists of a massive "rotary

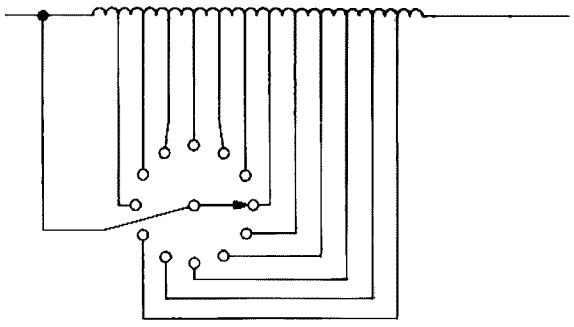

Fig. 2. No roller coasters in the junkbox? Then wind a coil of 30 turns on a 2½ in. former, and short out every few turns by means of a 12-way Yaxley switch.

roller" tuning coil and vernier dial reading up to 1326, which gives it excellent resettability. The coil is mounted on a steel metal panel, which is nicely sprayed grey, but the cabinet is typical "Army finish," and looks much better after a rubdown with sandpaper and a fresh coat of matching paint.

Although there is just room inside to mount the two switches, which were from an old TU5B unit, both the dummy-loads and tuning capacitor have to go up on top.

Now, if this particular item of "desirable surplus" is unobtainable, no need to worry, as practically *any* rotary coil of reasonable size will fill the bill – say, a coil of two to four inches in diameter, and from 30 to 40 turns.

What, no roller coasters in the junkbox? No matter, just wind a tapped coil and short out every few turns by means of a 12-way Yaxley switch, as in Fig. 2.

The tuning capacitor can be of any medium size, somewhere between 100 and 300 pF will be quite OK, but it *must* have wide-spaced vanes – at least as wide as those of the tuning capacitor in the PA tank circuit, otherwise it will spark across on peaks.

The dummy-load is a 50Ω high-current carbon resistor, ten inches long and an inch in diameter, mounted on three-inch standoff insulators. Keep it away from other components, as it dissipates all the rf output of the transmitter when in use, but as this should not be for more than a few minutes at a time under normal conditions, it can be over-run without too much harm. Switch it off when it smokes!

If you do not happen to find a large resistor of suitable value in the junkbox, wire up a string of smaller wattage ones in series-parallel to make the total resistance around 50Ω. Remember that they must all be carbon, not wire-wound, and given plenty of air space to cool them.

The meter shown in the photo is of the hot-wire variety, scaled to 1.5 A, but a thermo-couple type would be as good or even better, as its action would be quicker. The actual current shown varies considerably from band to band. Why not try an 0.5 A meter with a switch to shunt parallel resistances across it as required (see Fig. 3).

Bulb-holders should really be of the pot type, but Bakelite works all right clear up to 30 MHz. The high-impedance output to the long-wire end-fed antenna must exit through a porcelain "feed-through" type of standoff insulator, as there can be considerable rf voltage at this point on some bands.

Internal wiring should be as direct as possible, using short lengths of coax cable; please do *not* forget to ground *both* ends of the outer casing. All metalwork should be bonded with copper strip, not wire, and the unit itself bonded to both transmitters and station ground.

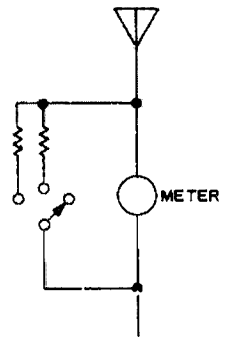

Fig. 3. If your meter knocks against the end-stop on some bands, wire a switch and shunts in parallel. Low-resistance shunts can be made out of old fire-element wire.

It is certainly not advisable to rely on the outer-sheathing of the coax cable for grounding purposes, as this can cause all sorts of problems, including getting a quick kick off the controls.

Your low-pass filter, swr bridge, and T/R relay should be wired together in the order

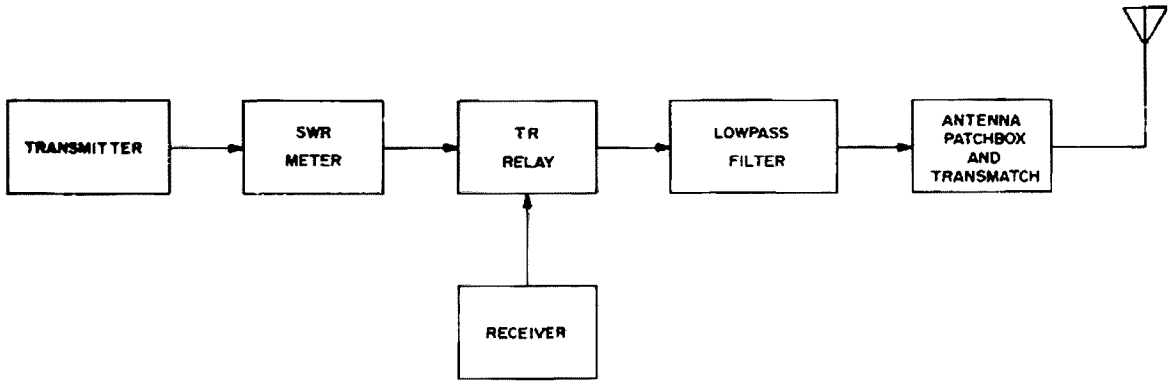

Fig. 4. The swr meter, T/R relay and low-pass filter are placed this way for minimum harmonics.

shown in Fig. 4, in order to keep harmonics down and TVI to a minimum.

Modus Operandi

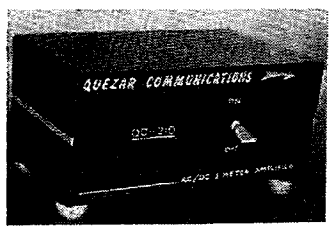
First, plug in coax leads from the transmitters, and do the same with the antennas. The output is switched straight through to low-impedance center-fed dipoles, ground-plane, and quarter-wave Marconi, but the end-fed random-length job (the one to the end of the garden!), is hitched to the standoff feed-through insulator, and fed via the transmatch.

Switch to dummy-load and tune the transmitter in the normal way. Flick the output switch to "transmatch," with the vernier dial at zero. Put the capacitor vanes at half-mesh, and wind away on the roller coaster handle until the rf-ammeter reads maximum. At this point, the meters on the transmitter should be back practically where they were when tuned into the dummy-load.

The capacitor can be used for final trimming, but remember that, when correctly loaded, the tuning should be very broad so that considerable movement of the knob will be required to produce any significant change in meter reading. This is the condition of highest efficiency, when the transmatch coil itself consumes a negligible amount of power. All the rf watts are going "right up the spout," where you want them, instead of chasing their own tail round the transmatch tuned circuit!

Although the roller-coaster coil will match any random-length of antenna into the low-impedance pi-output circuit of the transmitter, it should be realized that the actual amount of inductance required in circuit in the transmatch will vary considerably from band to band. For if the antenna happens to be a half-wavelength long (or a multiple of half-wavelengths), then it will present a high-impedance to the transmatch, so that quite a lot of coil will have to be "wound-up" in order to match the widely differing impedances. Whereas, if the antenna is a quarter-wave (or multiple) at the working frequency, then very little lumped inductance will be required in circuit.

The great beauty of the roller coaster is that there are no coils to change, no tappings to adjust, and nothing to do except wind away on that handle and stop when the rf-ammeter reads maximum. Once the correct settings have been noted (there's even a small plate provided on the front panel for this very purpose), it can be reset in a jiffy, without even using the dummy-load.



The Light Bulbs

While an electric light bulb does not make a precise dummy-load, as its resistance varies widely as it warms up, it is still a very useful guide when making adjustments to the transmitter. One instance is in modulation checks, for it gives a clearly visable sign of upward as well as downward modulation, and also the percentage of modulation as you whistle merrily into the mike. (Cries of Shame!) One bulb can be 10 or 15 watts for low-power jobs, and the other 150 or 250 watts for the QRO rigs.

The second use of these bulbs is in making a fairly accurate estimate of the actual rf output of a transmitter, together with the efficiency of the PA. For this purpose, two identical bulbs are used, one being wired to the 117V mains, and the other to the transmitter output. When they

With rack w/cabinet $115.00
TTL logic. Power line frequency counter for 3 minute or less timing and control. Easily re-programmable diode ROM uses only 27 diodes (depending on call) to send DE "any call". Low impedance audio with volume and tone control. All circuitry including PS on small G10 glass PC board. Write for full details. **HAL COMMUNICATIONS**, Box 365L, Urbana IL 61801

glow with exactly the same brilliance, obviously the wattage will be identical. A sheet of ground-glass placed in front of the two bulbs will assist in balancing, and of course keep bright lights away from the unit when judging. The efficiency of the PA is easily worked out by reading the final plate voltage and current meters. This experiment shows very clearly how the actual efficiency falls quickly as the operating frequency rises – try it and see the great difference between 80 and 10!

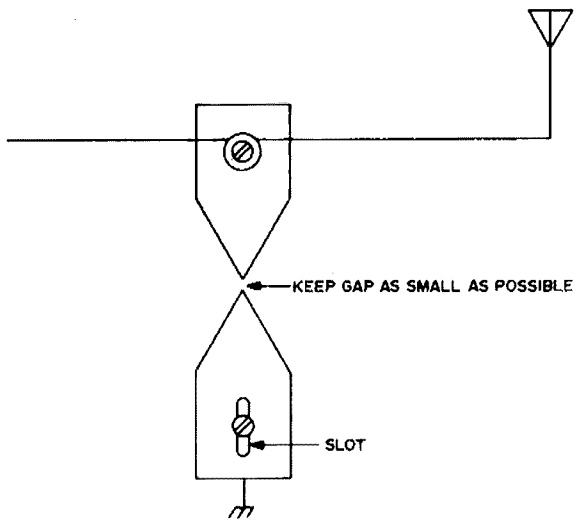

Fig. 5. This lightning-arrestor and static-discharger is easily made from odd scraps of copper strip or tinplate. In order to make adjustment of the gap easy, cut a slot in one plate so that it will slide up and down the fixing-bolt.

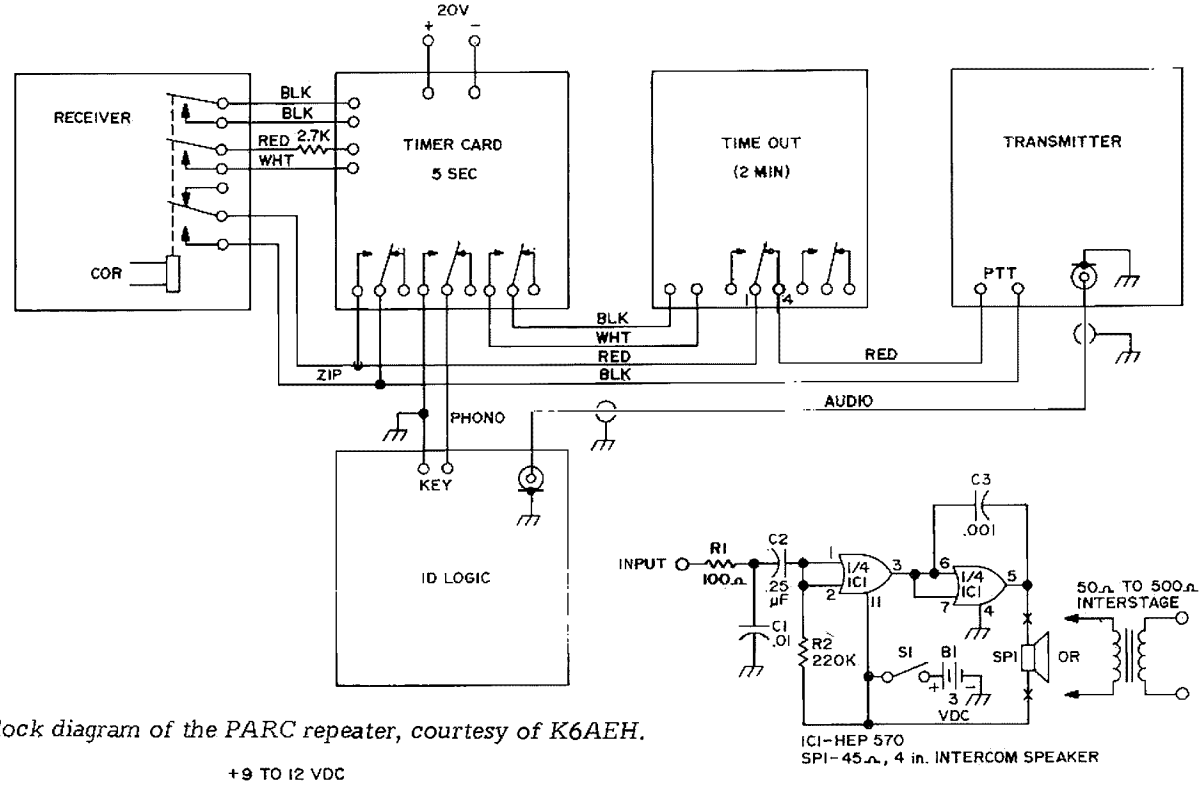
Whereas dipole antennas are normally grounded via their coax cable, the sheath going direct to ground in most cases, provision should always be made to ground long-wire antennas. This can easily be arranged inside the box by fabricating a little static discharger out of odd bits of copper or tin, as shown in Fig. 5. Keep the gap as small as possible, but not so that it sparks merrily when you press the key!

The photo was taken outdoors one sunny day with my ancient Leica. Technical details are: hand-held (very shaky) pan-X, 1/20th at f.12.6., developed in . . . but heck, what's all this photographic nonsense to do with 73 Mag?



Absolutely nothing at all, except that a lot of amateurs are also keen cameramen. And, it's one way of ending an article.

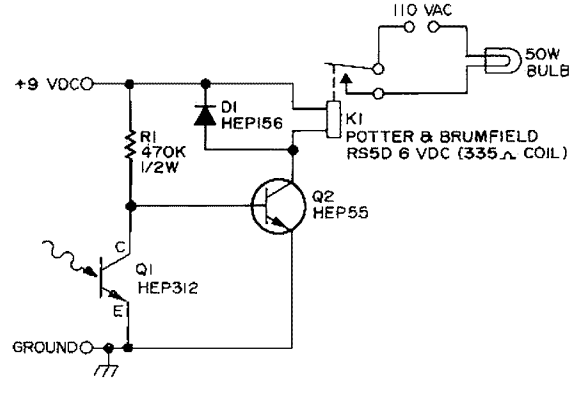
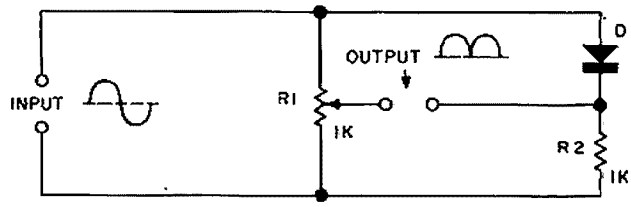
CIRCUITS, CIRCUITS, CIRCUITS...

The following circuits have appeared in the referenced books, magazines, application notes, etc. While we try to reproduce all of the information that should be needed by an experienced constructor, readers may want to avail themselves of the original sources for peace of mind.

Readers are requested to pass along any interesting circuits that they discover in sources other than U.S. ham magazines. Circuits should be oriented toward amateur radio and experimentation rather than industrial or computer technology. Submit circuit with all parts values on it, a very brief explanation of the circuit and any additional parts information required, give the source and a note of permission to reprint from the copyright holder, if any, and the reward for a published circuit will be a choice of a 73 book. Send your circuits to 73 Circuits Page, 73 Magazine, Peterborough NH 03458.



Block diagram of the PARC repeater, courtesy of K6AEH.



This burglar alarm will turn on a siren, bell or silent warning device. Additional switches may be added in series with SW1 and SW2; foil or thin wire may be used instead of SW1 and/or SW2. Courtesy of Motorola Construction Projects HMA-37.

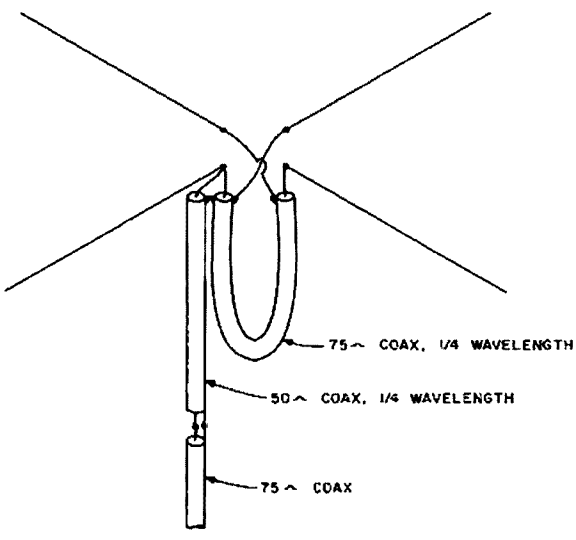
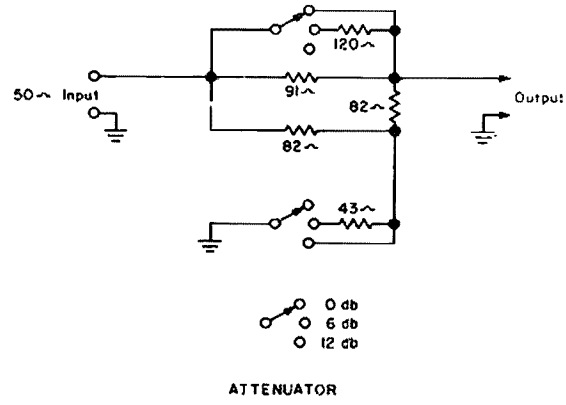
DVM adapter for a frequency counter. This circuits consists of a 200 k-ohm/volt input low pass active filter stage, a polarity detector and automatic switcher/indicator, and a voltage-to-frequency converter. The output frequency is adjusted so that 50 volts input will give a frequency of 5000 out. The three 25K pots are used for offset balancing. Any counter capable of readout to Hz is fine. Circuit by WØMLD.

Basic control unit which can be used for almost anything . . . timer, light activated relay, moisture detector, etc. The timer circuit will range from about 5 seconds to 50 seconds. Change R and C to alter range. The moisture detector normally uses a small printed circuit board with interlaced wire network to allow moisture to bridge the contacts. Light relay operates when light strikes the cell. Circuit courtesy Motorola HMA-33 Tips on using FETs.



Light dimmer which will handle up to 800 watts of incandescent lamps. 10 nF = .01 µF, by the way. Circuit courtesy of Motorola Semiconductor Power Circuits Handbook.



Video amplifier using a HEP 590 IC, courtesy of Motorola.

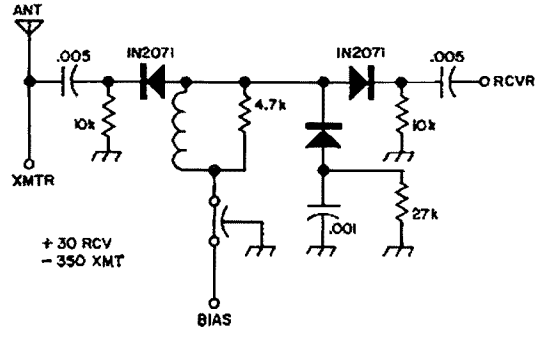
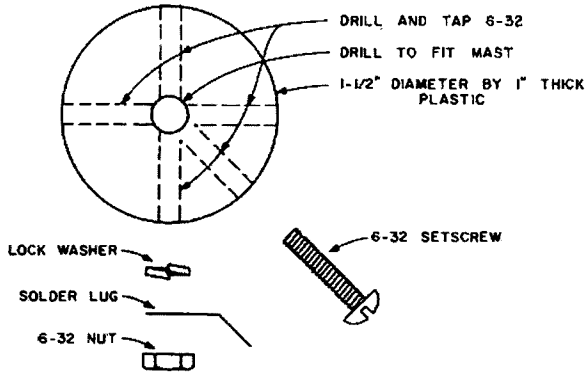
TURNSTILE HOOK-UP

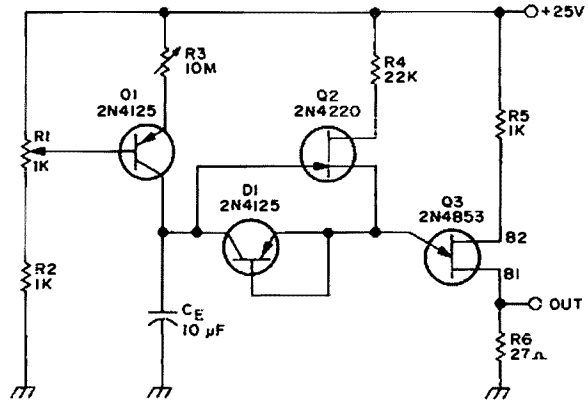


The Turnstille antenna, two dipoles phased 90° apart, is an omnidirectional horizontal antenna developed originally for mobile use. Dimensions for operation at 145 MHz are: elements — 19½" 1/8" brass rod; 50Ω coax Q-section RG59, 13½" long. Support details are shown below. From VHF Antenna Handbook by K5JKX, available from 73 for $3.00.



ATTENUATOR

50Ω attenuator circuit for a receiver front end. Use for measuring effectiveness of different antennas by listening to a constant amplitude signal.



W1OOP

This is a high-frequency antenna switch using diodes. From the Diode Circuits Handbook, edited by WA1CCH, available for $1.00 from 73.

TURNSTILE SUPPORT BLOCK

Long duration FET timer which will give a delay up to 10 hours. Circuit courtesy Motorola Semiconductor Power Circuits Handbook.

An Aural Transmitter Tuning Aid

Florian J. Fox W1KPN
219 Plymouth St.
Stratford CT 06497

A transmitter can be tuned by adjusting the various circuits for maximum power delivered to the antenna feedline. If the standing wave ratio of the antenna system has been adjusted for a reasonably low value, the antenna feedline voltage will, as in the case of an swr bridge, serve as an indicator of relative output power. And relative power can be indicated by means other than visual meter deflection.

With my homebrew SSB rig I use either of two methods to obtain rf output for tuning. In the CW mode I reduce the rf drive by adjusting the carrier injection control to such a level that the final amplifier tubes can not possibly be overheated. In the sideband mode I apply about 20 mV of 1 kHz audio to one of the mike input jacks, having previously set the mike amplifier gain so that the final plate current increases to a safe steady state value when the transmitter is tuned and loaded. Since most rigs do not have two mike input circuits, some additional equipment must be provided if this method of obtaining output rf is to be used.

One big advantage of using the "audio tone" method of generating rf output for tuning an SSB rig is that even when the tuned circuits are far off resonance, the final amplifier plate current will be the normal no signal idling current. This current will increase only when the circuits are tuned and loaded, and if the audio level has been properly restricted, the final amplifier tube, or tubes, can never overheat.

If, as is usually the case, the transmitter has only one mike input jack, it would be undesirable to require the handicapped operator to change the mike amplifier gain setting once it has been adjusted for him. Therefore, the audio oscillator should be provided with an output control so that audio level can be set without disturbing the mike gain control setting. The adjustment of the audio oscillator output is quite simple. Gradually increase its output voltage, when the transmitter has been tuned and the correct mike amplifier gain has been set, until there is a noticeable increase in the final amplifier plate current, a value that will not overheat the tube, or tubes, even if left on for a long time.

The diagram of Fig. 1 shows the tuning concept as a complete system. The circuits needed are the tone oscillator (Fig. 2), a rectifier unit (Fig. 3), and a control box (Fig. 4).

In the case of CW or AM transmitters, since they always produce rf output, the introduction of an audio tone would be useless. Some means should be provided during tuneup for reducing the output rf carrier to a safe level when circuits are off resonance.

Let us now consider the CW method of tuning commercial SSB transmitters. One of the switches will have a position marked TUNE or TUNE-CW and usually a control marked RF GAIN which is used for adjusting the transmitter rf output level. In some cases it is not possible to set the rf gain low enough to prevent the final amplifiers from overheating when the circuits are off resonance. This is why the owner will be cautioned not to tune for longer than about 15 seconds at a time. This could be a real problem for anyone who has to use an

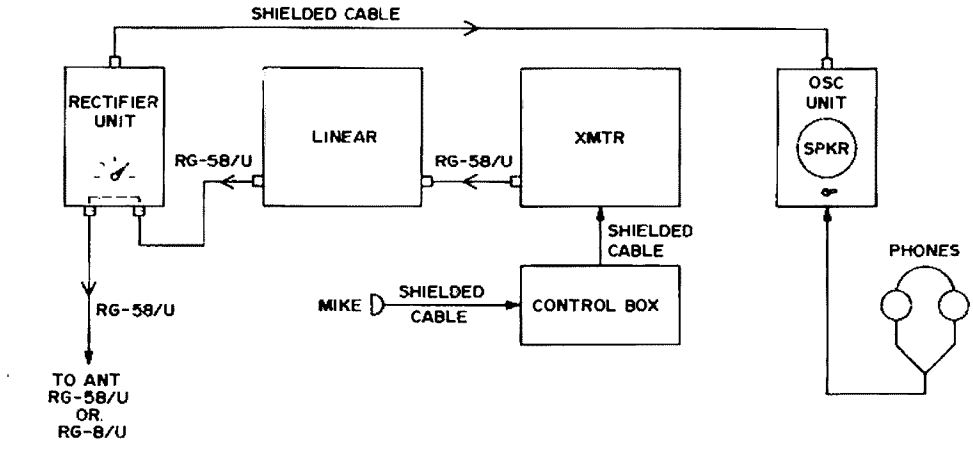


Fig. 1. Block diagram of complete installation.

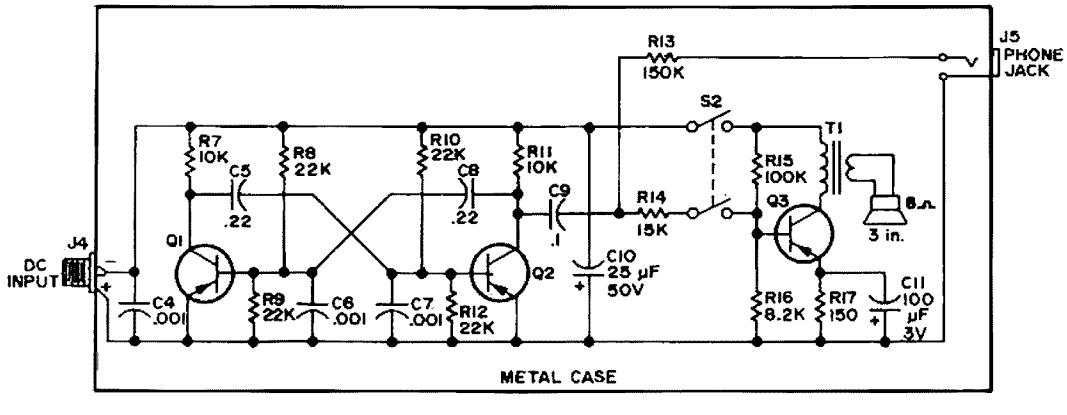
external tuning aid. It would be well to check this point very carefully before deciding which of the two tuning methods should be used. If there is any chance of damaging the final amplifier tubes, the audio tone method described previously should be used.

This tuning aid has at least two advantages over some of the others that have been published. It is not necessary to make changes or additions to the transmitter, and no external power source is required. Even though it may draw several hundred milliwatts from the coaxial line that feeds the antenna this does not matter because it is disconnected from the feedline when the sensitivity switch is turned off.

Rf voltage in the antenna coaxial feedline is rectified and filtered, producing a dc voltage which is proportional to the rf voltage. This dc voltage, which attains a maximum value when the transmitter is properly tuned and loaded, is applied to a transistor multivibrator oscillator. The output of the oscillator is fed to a headphone jack or it can be switched to a transistor amplifier driving a small loudspeaker. Any variation of the dc supply voltage will change both the frequency and the intensity of the tone produced by the oscillator. In other words, when the rf voltage in the antenna feedline increases, the frequency and intensity of the audible tone will also increase and vice versa.

Originally the tuning aid was enclosed in a single metal box, but in spite of the filtering, there was so much stray rf that the multivibrator would block at high rf input levels. The layout of the parts made it impractical to add shielding partitions, so



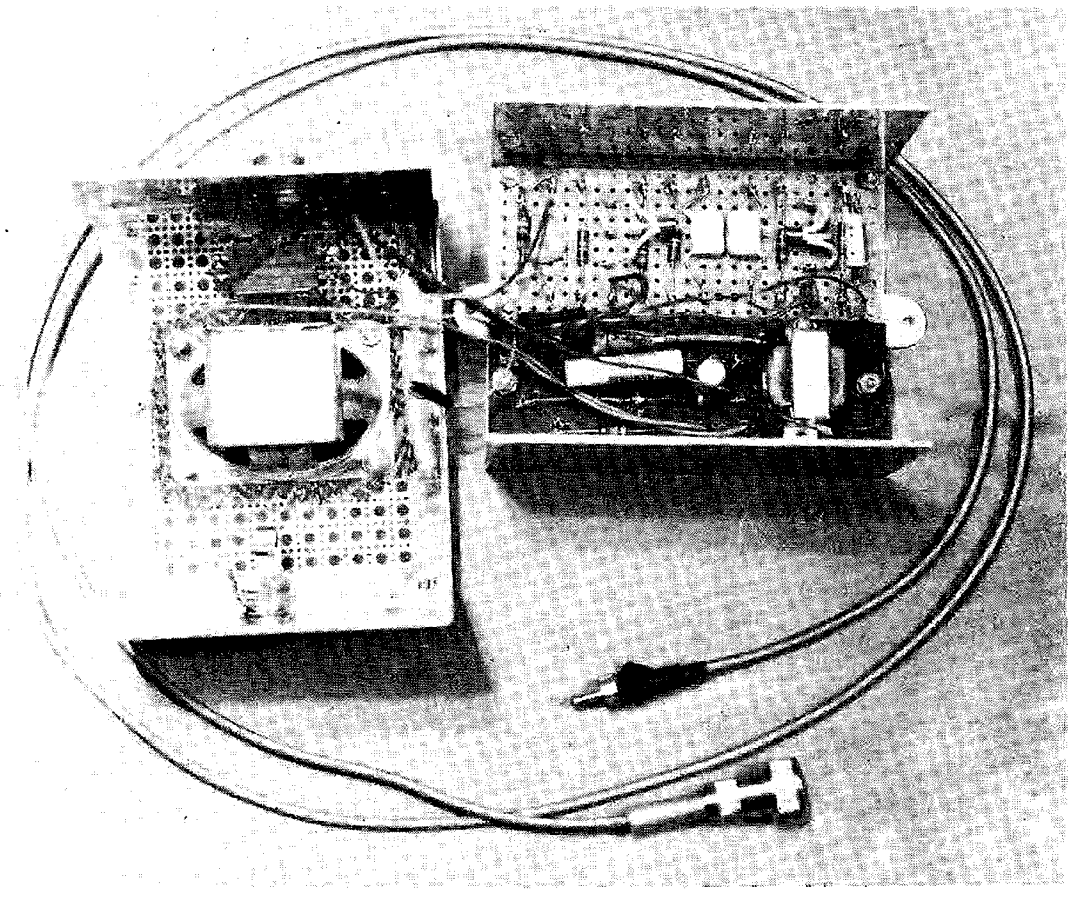


Fig. 2. Oscillator unit. Q_1, Q_2: 2N4354; Q_3: 2N270; resistors ½W size (or smaller): C_4, C_6, C_7: ceramic; rf bypass (value not critical) .001 MFD used; C_5, C_8: .22 MFD paper +/– 20% tol.; C_9: .1 MFD paper +/– 20% tol.; C_{10}: 25 MFD 50V electrolytic (value not critical); C_{11}: 100 MFD 3V electrolytic (value not critical); T_1: Output xfrm pri 1000Ω impedance (approx) sec. 8Ω or 3Ω depending on speaker V.C. – 300mW size, stancor TA43 or similar; S_2: Double pole single throw switch.

The Oscillator

the problem was solved by the use of two separate metal boxes, one for the rectifier unit and one for the oscillator. A single box probably could be used if the two sections are adequately shielded from each other.

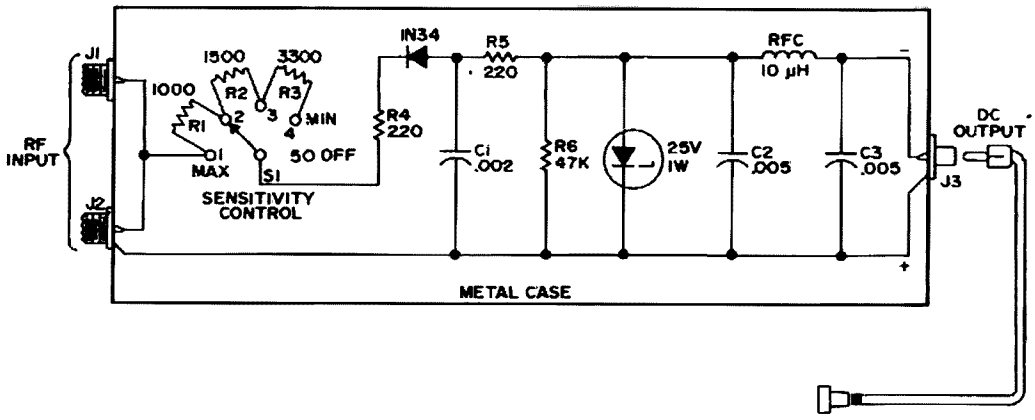
Construction

The construction is relatively simple, so a detailed discussion is really not required. And since the circuit diagrams and the photos tell most of the story, I shall confine myself to offering a few suggestions. The miniboxes I used measured 2¼ x 2¼ x 5 in. for the rectifier unit and 3 x 4 x 5 in. for the oscillator, amplifier, and speaker assembly. Anything smaller will result in crowding. Install the antenna feedline connectors close together. For constructing compact assemblies, Bakelite punch boards with insertable terminals are very convenient. After the boards have been cut to size and mounting details worked out, it is wise to make sketches, preferably to scale, to determine the most logical placement of the components for easy wiring. If the final sketch, showing all interconnections, is made on tracing paper, the sketch can be turned over so that the back side of the board can be wired with less chance of error.

The interconnecting cable between the two units must be well shielded against stray rf pickup. Coaxial microphone cable or RG-58/U will be satisfactory. The type of connectors is optional.

The frequency variation of the audible tone will decrease when the sensitivity of the tuning aid is reduced. This is due to the increased series resistance in the rectifier circuit. For best results, hold down the transmitter output as much as possible so that a more sensitive setting (less series resistance) can be used. If there is a linear amplifier, tune the exciter first, then reduce the sensitivity and tune the linear.

The headphones should be of the high impedance type – the higher the better. If more volume is required, reduce the value of series resistor R13, but not below 47 kΩ.



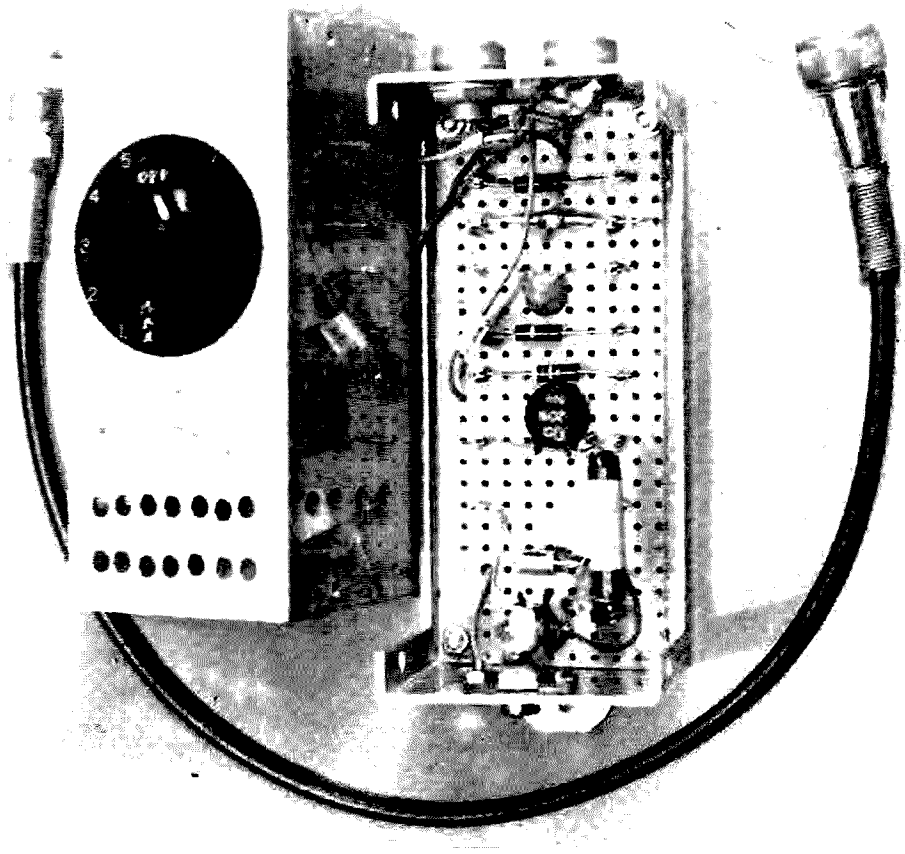


Fig. 3. Rectifier unit

The headphones should be of the high impedance type – the higher the better. If more volume is required, reduce the value of series resistor R13, but not below 47 kΩ.

If more loudspeaker output is required, the 15 kΩ transistor base limiting resistor (R14) can be reduced to about 4.7 kΩ as a limit. If still more output is required, base bias resistor R16 can be increased to around 12 kΩ. But since this will cause the transistor to draw more current, there will be some reduction in the range of the tone variation. It might be better to shop around for a more sensitive loudspeaker.

When using the headphones for tuning, switch off the loudspeaker. This reduces the current required by the unit, which increases the dc voltage variation, and this in turn increases the change in pitch and intensity of the tone.

The speaker switch can be eliminated if you can find a phone jack having two separate normally closed switching circuits

The Rectifier

which will open when the phone plug is inserted.

To install the tuning aid, first select a location for the rectifier unit so that it will be easy for the operator to find the sensitivity control. Remove the antenna feedline from the transmitter output receptacle and connect it to one of the rectifier rf receptacles. (I should have mentioned earlier that these rectifier receptacles should preferably be the same type as used on the transmitter.) Make up a coax jumper cable to go from the transmitter to the other rectifier rf receptacle. Next find a convenient location for the oscillator unit. Make up and install the interconnecting cable between the two units.

If it is desired to tune in the SSB mode by injecting an audio tone into the mike input jack of the transmitter, it will be necessary to make a small audio oscillator having an adjustable output. Its frequency can be between 400 and 1000 Hz and its maximum output need not exceed 50 mV. A compact transistor oscillator, powered by a single penlight battery, can be made up with little effort. The oscillator, a mike jack, a switch, and a shielded output cable should be installed in a small metal box, as shown in Fig. 4, to enable the operator to inject the audio tuning signal by simply throwing a switch. Be sure to procure the same type of jack and plug that is already being used on the microphone and the transmitter.

...AND MORE!

Enclosed is our 3-year renewal check. Because of our comparatively long term as subscribers (10 years) we feel entitled to a "beef."

Why must your layout-man make the working drawings of schematics and PC board layouts so very tiny as to be impossible to use effectively and yet he wastes much good space (almost half pages) for just the titles of articles. True, the layout is attractive, but the space might better be utilized in making the diagrams and drawings larger and more easily legible – without microscopes.

Bob Cardinali WA2ZXT
Fulton NY

You said it. . .

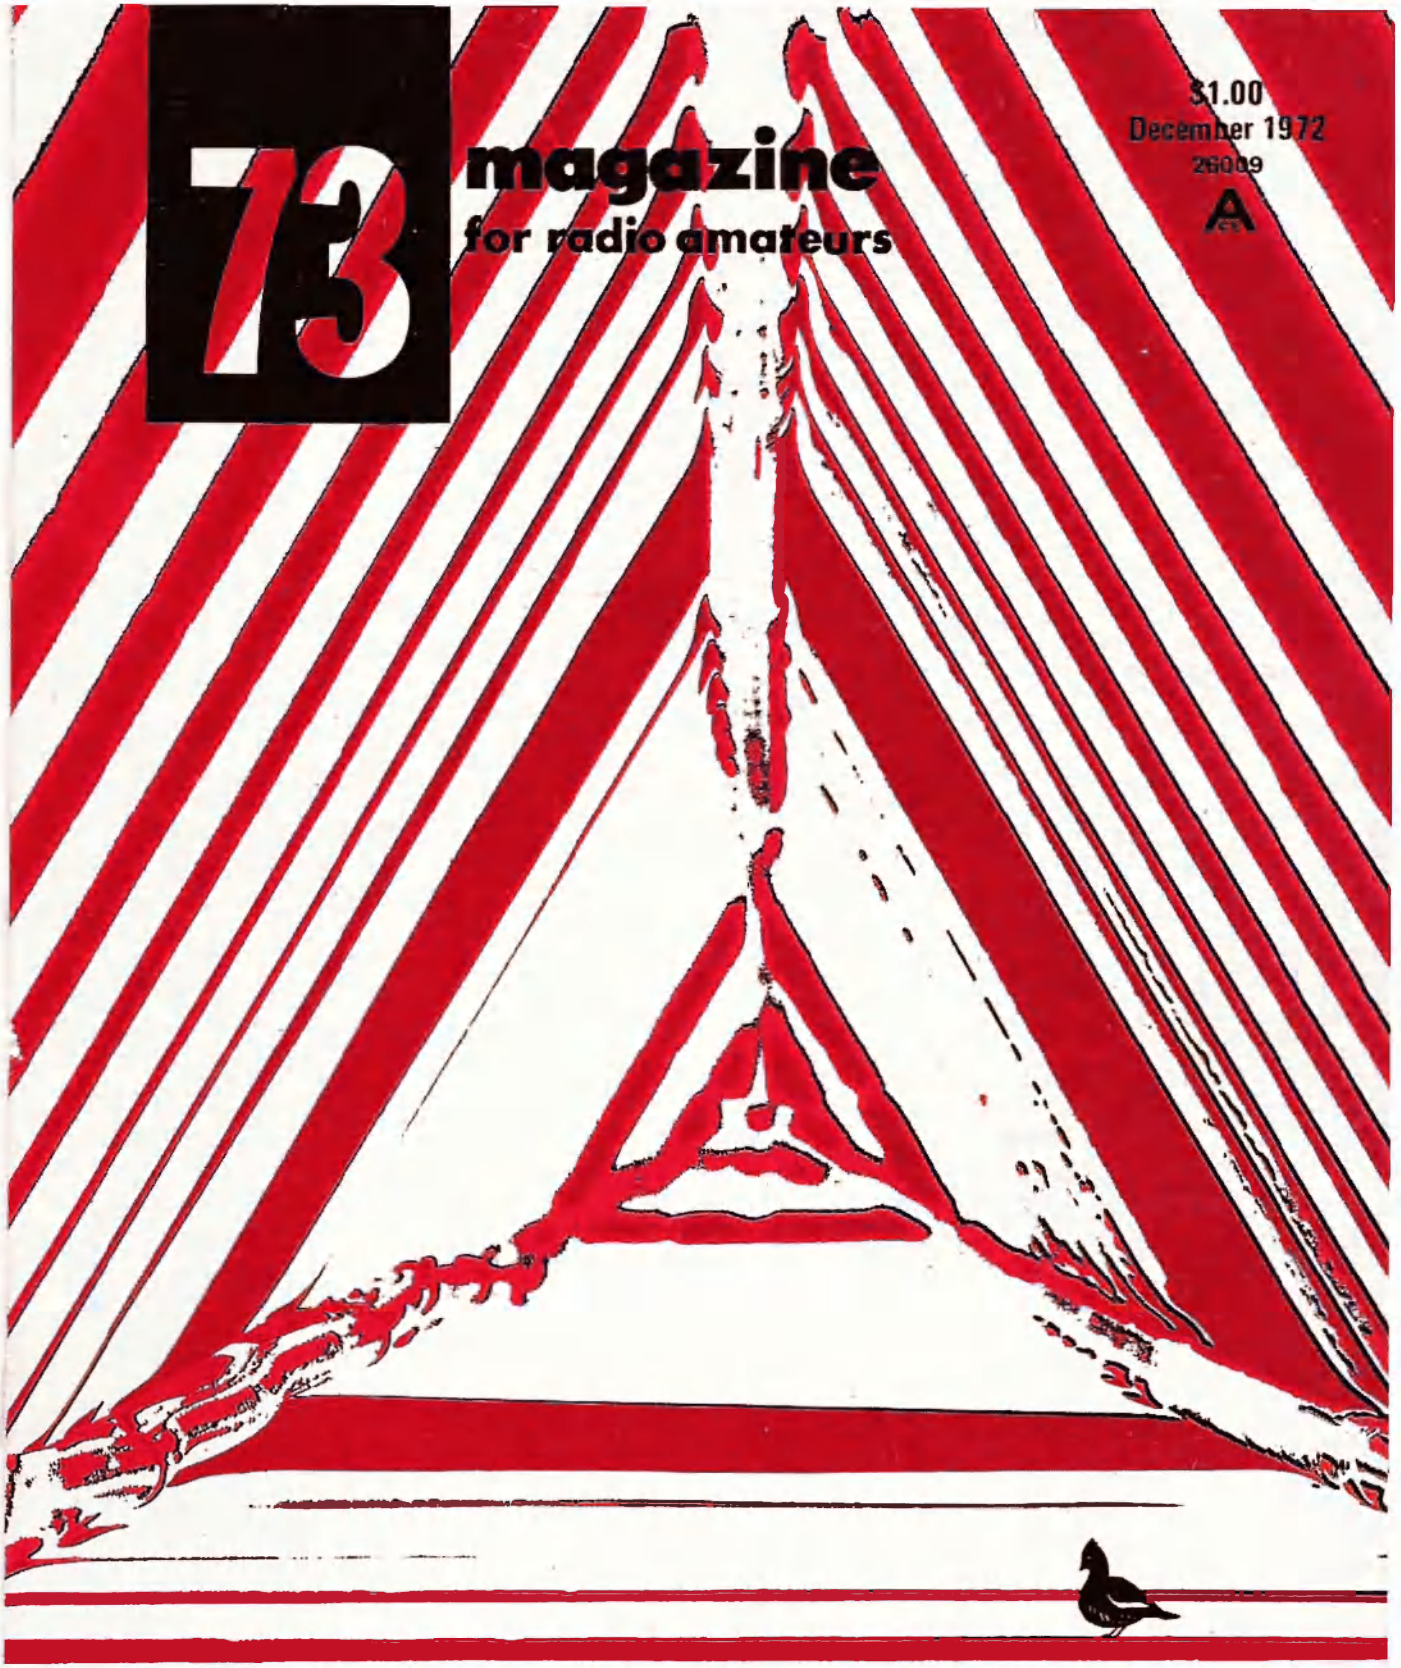
Having subscribed to your publication for a number of years and enjoying every issue, or I wouldn't buy every three years, I'd like to offer a suggestion that in my opinion is VERY important.

If you still delve in tubes you obtain a manual and as a rule find out what you need to know. We're now in the tens of thousands of solid state devices and more coming up. You'll never get a manual that will cover the info you want.

It is my suggestion that every schematic printed have the "bottom view" showing E/B/C/ etc. Present prints are good on IC's but they sure could make building a lot easier and the originator has this info.

Fred Pursell W1DEM
Mont Vernon NH

The article (The HW-16 on Phone, by Jim Reichler WN2REW) in the August 1972 issue was of great interest to me. There is only one problem, the HW-16 does not have selectable sideband. Since 40 meter phone is on lower sideband and the rig receives upper sideband, even with the filter modification described, you would still be unable to copy 40 meter phone.



Or did I miss something in the fine print.

E. I. Fullmer WB6MKA
Glendora CA

What you missed was the schematic showing a switch shorting out the crystal filter. Shame! With the filter gone could you really expect the transceiver to retain seletable sideband?

COVER: The pattern of covers from September to October to November obviously was heading us to disaster in December. Amateur radio just isn't ready for a nude cover yet, even if we could arrange such a thing. So, thanks to W2ANT, we have a nice picture of a tower which, hopefully, will not lead to too many adulterous thoughts. If you still have such thoughts, then we suggest a visit to your minister.

73 Magazine is published monthly by 73, Inc., Peterborough, New Hampshire 03458. Subscription rates are $6 for one year in North America and U.S. Zip Code areas overseas. $7 per year elsewhere. Two years $11 and $12 overseas. Three years, $15, and $16 overseas. Second class postage paid at Peterborough NH 03458 and at additional mailing offices. Printed at Menasha, Wisconsin 54952 U.S.A. *Entire contents copyright 1972 by 73 Inc., Peterborough NH 03458.* *Phone: 603-924-3873.*

You liked the November issue? Something like that could happen again if you don't stop spending money on your hobby and having fun with FM and such. The January issue promises to be another whopper — in case your subscription is running out — or you have a friend who needs a hernia.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

OPEN LETTER TO W2TUK

Okay, Harry, you've been president of the League for nine months now and you've had time to get settled into the job.

Your speech at the Hudson Division convention was particularly interesting to me – especially that part about talking with amateurs in other countries from a handy talky via satellite. It would have been gross of me to pop up and ask you right then, in your moment of glory, on what band this great QSO was going to take place. But I sure wanted to.

The main bands that could have been used for this were the amateur 1200, 2300, 3300, and 10,000 MHz bands – all of which were lost for that purpose at Geneva last year. Harry, how are you going to go about getting those bands back again so that mythical contact can take place?

The ITU left us with parts of the low bands – 144–146 MHz – 435 438 MHz, and above 24 GC. There isn't possibly enough room for what you proposed in the 145 and 435 MHz bands, so this sticks it up on 24 GC. Harry, unless you know something I don't, we don't even have a hint of an idea of how to set up anything useful for that band – we don't even have anything in prospect that might someday develop.

My open letter, in lieu of being the gadfly at the ARRL convention, asks you to tell all of us what the ARRL intends to do about getting back the recently lost satellite amateur bands. Since the future you held out in your speech would seem to be possible only by the use of the lost bands, there is an implicit promise of a return of these frequencies.

It is my understanding, in talking with the FCC and many, many others who are intimately involved, that these amateur satellite frequencies have been irrevocably lost – and lost through a lack of preparation for the ITU conference. It comes down to this: either you have some plan for getting back the lost frequencies – or you have some great breakthrough for 24 GC – or you were giving a political speech with nothing to back it up. That would be cruel.

Harry, the pages of 73 and QST are open to you for an answer . . . if you have an answer.

The FCC and ARRL

A quote in a recent issue of CB Magazine is quite illuminating. Richard Everett, attorney for the Amateur and Citizens Division of the FCC was asked: "What is the relation between ARRL and FCC?"

Mr. Everett: *"The ARRL started in 1913 and represents about one-third of the amateurs. They have older members and are very technical minded and file information on rule-making. None of the older members* (of the FCC) *are now members of the ARRL and most of the staff members have resigned from ARRL, especially the ones in my section."*

What can ARRL do to change its image? How can ARRL regain its lost prestige? Though the number of younger amateurs is down, for several obvious reasons, something really should be done to make the ARRL more attractive to them so the average age of the members doesn't continue to climb – it's over 40 now, isn't it?

The FCC and 220 MHz

A recent issue of *Electronics* had a very interesting special report on the EIA and FCC plans for our band. Quote:

"The FCC is on the verge of taking some action on EIA's proposal, confirms Prose Walker, chief of citizens radio operations at the FCC. But any decision in favor of citizens radio is expected to come hand in hand with a requirement that citizens-band transmitters be equipped with automatic identification circuitry."

Well, there it is. Do you still really believe that the EIA is not able to get action by putting pressure on congress? Do you really believe that the 220 band woulc not be perfectly safe if amateur radio had a good Washington lobby? There is no question about this in the mind of anyone who knows politics.

You know, if every amateur spent one half dollar a year on a man in Washington, we could have an expert, complete with a healthy expense account, to stick up for us where it counts the most.

NEW YORK SYMPOSIUM DECEMBER 7TH

The first New York FM Symposium will be held Thursday evening, December 7th, at Lazzeras Cafeteria, Maiden Lane and Pearl Street in downtown Manhattan. This will be hosted by the WAS2SUR repeater in cooperation with 73 Magazine and the Repeater Bulletin.

The symposium will be in three parts – the technical sessions – a rap session for groups with inter-repeater problems – and a frequency coordinating meeting for repeaters interested in changing channels.

The technical symposium will come first with discussions of duplexers, circulators, intermod problems (and their solution), narrowbanding receivers, and such.

The gathering will start at 7:30 for dinner. At 8:30 the regular Symposium will start. At the end of the technical sessions there will be an opportunity for the repeater representatives to get together and try to solve their inter-repeater problems. This will be the first forum provided in New York for this. If it seems worthwhile there will be more.

After the hassle and hock session there will be an opportunity for groups in search of coordination to get together and work out channel problems. The frequency coordinators are under a mandate from the recent repeater association meeting not to hold pairs away from repeater groups that need them and are ready to use them.

Would it be possible for the New York repeater groups to start the nationwide swing to one meg splits with 20 kHz separation? They need the 48 channels of repeaters more than any other part of the country – so who knows?

The Symposium is a joint venture of the WA2SUR repeater and 73 Magazine, by the way. If enough people turn out for this meeting and the opinion is that there should be more, there will be more.

HOW MANY REPEATERS?

A group of repeater owners recently cheered when someone got up at a meeting and said he thought 27 repeaters in any one area was plenty.

The discussion had been on suggestions that repeaters change from the present system of being 30 kHz apart and move to 20 kHz spacing – to-

gether with a 1 MHz split between input and output. This would provide about 48 repeater channels where there are presently only 27, and would also make it far simpler to set up repeaters with sensitive receivers.

How many repeaters are best for any one area? There is no way to tell from the pattern around New York, Chicago or Los Angeles, for all are different, and all leave a lot to be desired.

There are about 25,000 licensed amateurs in and around New York City. Fortunately for the local repeaters only about 1500 of these are active on FM so far. Interest is growing rapidly though and the number is escalating. It is possible that we could see one third to one half of the total getting into the FM act in the next two or three years. The rigs are inexpensive – the repeaters are there – and it's loads of fun.

In New York there is one repeater with over 400 active users – WA2SUR. It is a madhouse – typical of New York. There are a few small repeater groups who discourage non-members from using their channels. There are a few medium sized repeaters – perhaps two hundred users, such as WA2KEC and WA2PDJ. Some of the northern New Jersey repeaters are fairly busy too. There are about twenty two meter repeaters in the area at present.

If 10,000 amateurs go FM in the New York area; 27 repeaters will all sound even worse than WA2SUR. Forty-eight repeaters will make a lot more sense.

And what if the number of amateurs should increase and we should find that we have 20,000 FMers in New York? We will sure be glad for 220 MHz!

TAGGED FEEDLINES

Some repeater operators were a bit piqued at the FCC requirement that remote transmitter feedlines and antennas be tagged. They felt that this would help those who might be bent on mischief to cut the right coaxial or control cables at repeater sites. They were also put out that amateurs should have to do this when business repeaters have no such mandate.

The complainers were quieted by others with the argument that, after all, this isn't a serious problem – and since so many other of the new regulations are so much worse and so much more worthy of battling about, that it would be better to swallow a few minor bruises than to fuss about so many things. By accepting this restriction they felt that the FCC might be more inclined to give on the more bitter pills.

STANDARD ID TONE

An excellent suggestion came up the other day for standardizing the tone used for repeater identification – why not use 1020 Hz for this and build rejection filters into our receivers which will keep us from hearing it unless we want to?

Why 1020 Hz? That's the tone used by aircraft, so the filters are already available in quantity at low cost.

It is nice to find out what repeater you are using when you aren't sure, but once you know it is a bore to have to stop and listen every few minutes as it identifies day in and day out.

FM = FRIENDLINESS MACHINE

Have you ever called in on a repeater when you were visiting a new area only to be met by someone with a crabby disposition? It sure sours the experience. It happens to me every now and then.

If you have a regular user of your repeater who takes delight in putting newcomers down, why not form a posse and try to explain that FM is supposed to be fun and friendship – and that putting people down may be fun for him and build up his faltering ego, but it is a drag for his victims.

You can easily set the stage to dump on virtually every new user of your repeater and have a ball making everyone feel bad. For instance, you can set up a rule that says that no one can call in saying "break." Fine. You'll have loads of customers for a put-down, since virtually every FMer has been trained right from the beginning to put in a "break" before jumping onto the channel.

With a no-break rule you can work out a little passion play for your victims. When the visitor calls in for the first time with a break, you exclaim in exaggerated panic – "breaker on frequency – emergency – come in the breaker with the emergency!" While you may not cure the visitor of being an FMer forever, you will certainly have made him wish he had never tried to talk with your group. And don't think that a condescending explanation is going to smooth things over. There is no way to repair the damage you've done.

Another favored put-down is to break in on a conversation on "your" repeater and frostily announce that this repeater is for emergency use and that rag chewing should be done on other channels. This is the YYQ approach to driving people off FM and it has been used indiscriminately. It is guaranteed to make everyone involved madder than hell – if that is what you want. It is insufferable childishness like this that brings on jamming and profanity.

If you have any really raunchy rules for your repeater – rules which are certain to generate more heat than fun, perhaps it is time to think them over and amend them. FM should be fun – fun for the regulars – fun for the visitors – fun for everyone involved. When new FMers call in, expect them to need some help and be nice about it – make FM fun for them, even if they cause a little aggravation the first time around.

Any comments?

SINGLE FREQUENCY REPEATERS

Motorola has a license (KQ2XQU/ Ft. Lauderdale FL) to experiment with a single frequency repeater on 557 MHz. We assume that this may be done with a time splitting arrangement via a chopper circuit. If anyone has any details on how this might be done the readers of 73 will certainly be interested.

DXers ARISE!

How are your QSL bureaus doing for you? 73 has received zero letters of complaint, so it is assumed that everything is going smoothly. Funny how no one notices the bureaus much when they work – but when something goes wrong – wow!

The W2NSD/1 cards have been coming through the Northern New Jersey DX Association QSL Bureau without a hitch for quite a few years now. Surely no other bureau can be doing better than this group. Huzza for the dedicated DXers who sort through thousands upon thousands of cards every month – with no pay – and with darned little praise.

If you have worked any DX you undoubtedly have some cards gathering dust in the files of your local QSL bureau. They're listed in QST, so the next time you work a League member, you can ask him to look it up for you. The bureaus normally keep cards for three years before throwing them out. And they really hate filling trash cans with cards from JT, CR9 and other really rare ones – but out they go! If you haven't an envelope with your bureau, better get on it.

What's With RACES?

Non-hams using our precious Fm repeaters? You bet! Apparently I need some more information on just exactly how RACES is set up. I was under the mistaken impression that this was supposed to be an emergency use of amateur bands and that licensed radio amateurs were supposed to be organized in nets – including FM repeater operation.

But apparently in some areas of the country the local RACES director has

set up non-amateurs with equipment to work through the repeater using the repeater call and a unit number instead of a regular ham call.

Fellows, when you run up against non-licensed users of our bands please make an inquiry and send all the details you can to *73*. There may be some emergencies where none of us would have any objection to non-ham RACES personnel using our bands, but I think most of us would like to encourage regular users to get their ham licenses.

WINDJAMMER OPPORTUNITY

There is an interesting opportunity for one or two amateurs with marine knowledge and experience to get a half fare rate on the Yankee Trader around-the-world cruise. The regular rate is $18 per day - but someone who could help to operate and service the loran, radar, and radio gear could have the adventure of a lifetime for about $9 a day. The gangplank goes up soon, so get cracking.

Can the Amateur Industry Organize?

There would seem to be some persuasive reasons for the manufacturers of amateur equipment to get together and work out some solutions to the more pressing amateur radio problems - like how to get more hams – how to keep the FCC from taking away the ham bands – how to keep the FCC from cutting back, bit by bit, on amateur privileges.

The industry has attempted to organize in the past, only to be thwarted by the ARRL, which may not do very much to help the hobby grow, but is ever alert to any possible threat to their power.

An investment of one percent of the gross receipts for sales of amateur equipment would provide a fund which could be used to encourage the growth of the hobby. How much would it really cost to have one retired ham, knowledgeable in public relations, who could organize the better ham writers to provide articles and stories about the hobby and sell them to the top magazines? Almost every major magazine would love to have a good ham radio article now and then – unfortunately there is no one (or group) to organize this, so we get no exposure and our hobby is confused with citizens band.

With a little promotion the growth rate of amateur radio would be right back up there where it was in the 50's – maybe better. This would bring new life to our clubs – more enthusiastic operators to fill in the empty bands – and maybe even more QRM on Sunday afternoons, if that is possible. One million amateurs would not seriously strain the spectrum we have available, but it could bring about a great deal more respect from the FCC and perhaps save us from the devastating rule changes.

MENSA NET

More and more amateurs have been joining Mensa and the result is a regular net. It meets on 14.280 at 1800 GMT on Saturdays according to WA6KGP. Amateurs interested in joining Mensa can drop a note to 73 Magazine, Peterborough NH 03458 and get a little brochure telling about it. The only qualification is an IQ of above 152.

MORE COLUMNISTS

There are two more aspects of amateur radio that we would like to cover regularly in the 73 newspages – contests and certificates. It is possible that we might be receptive if someone who was seriously into these things offered to keep the 73 readership informed.

We might even be able to add some pecuniary interest to your amateur radio hobby.

If you have better than average connections on keeping up with certificates and awards, and are interested in preparing capsule facts on them for the 73 newspages, drop a line to us.

Ditto contests. Readers would like to know what contests are being run, when and enough data to get started in them or send for full rules. We do want to leave CQ as the source for exhaustive details on contests and just bring a synopsis to 73. Anyone with good bona fides interested?

NOVICES UPTIGHT

One of the most persistent complaints heard at the Hudson ARRL Convention was a chorus of gripes from Novices about the latest CQ action. It seems that CQ has been sending Novices a note telling them that they will receive a six month free subscription to the magazine. Then, after an issue or two, along comes a note saying that this subscription is an impossible burden and they really should foot their share of the cost and how would they like a two year subscription for $6.00?

ARTICLES NEEDED

Quads. Interest is high in quads and it would be nice if we could run a special issue full of quad articles. How about it you designers and builders?

Matching of VHF beams could use some coverage too – any "experts" out there who own a typewriter? And please write it so the average VHFer can use the material – forget the Smith Charts and gobbledegook and keep it to practical how-to-do-it instructions.

Slow scan – almost anything that hasn't been printed on this should be – we can use a whole bunch of articles.

FM – although we are not packing every issue with FM articles, we still want to keep ahead of all the other ham magazines. Circulators – isolators – solutions to intermod – to desensing, and, like slow scan – anything that hasn't already been published should be. We'll run articles, books, just circuits, whatever you have.

Antennas – if you have any new ideas they should be written up and we hope you'll give 73 first choice.

Novice VFO's – let's go on this one!

Several readers have asked that we try to publish more articles for the beginners, keeping in mind that there are readers who are not only non-engineers, but who are still not really sure about how a volt-ohmmeter works. Some of you readers who have been teaching the General license exam might make a note of the points that need to be covered and provide helpful articles on them. We could also use some simpler construction projects for the amateur who has always wanted to build, but who has been afraid to get started.

Wayne

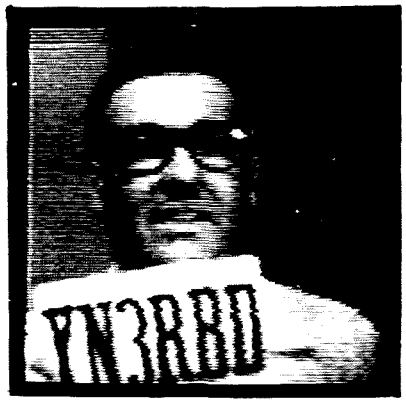
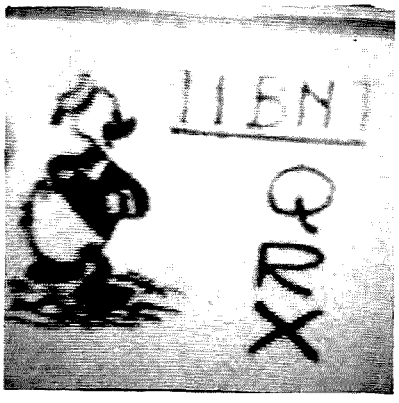
Birmingham AL 35210

An item of growing interest in slow scan conversations is binary, or computer types of, storage devices. Although present costs are considered high, this should drop in the near future as manufacturing methods advance. MOS Storage, or "memory" units can be used to store a slow scan picture in the form of "bits" of sync and video information. Naturally, this can be "programmed" or "replayed" at will. Quite a group of possibilities, eh? The present cost is approximately 1 (one) cent per "bit" and a typical slow scan picture has around 12,000 "bits" of information, so immediately there's a cost of $120. However, watch this interesting market. A substantial price reduction will no doubt open new slow scan horizons, such as

ZS3B's African cartoon as received by WB6LSX – good detail for such DX.



all electronic I.D. units, or slow scan stored and fast scan reproduced pictures (which could be viewed on your regular TV). And, if this can be accomplished with one frame, it can be accomplished with three – one red, one blue and one green, which again could be viewed on your regular color TV.



W1VRK as seen on the slow scan monitor of ON4DN.

Mohammed, 9K2AM, has been rather active on slow scan lately. If you would like to work him try watching 14.230 kHz around 1200 GMT. This is also a good time to watch for ET3DS and ET3KH, two more newcomers to slow scan.

I understand Mike Tallent is developing a direct sampling circuit for fast scan cameras, that will require no internal connection to the camera. Just connect it to the fast scan output and it gives out with full slow scan. Possibly in 1973 this will become available on printed circuit boards, as his monitor circuit is at present. I can see the results now – slow scanners clamoring to TV stations, sampling rigs in hand, and slapping them on the TV station's switcher output. Then recording a pile of programs with full zoom pictures, studio lighting, special effects – gad, what a ball!

YN3RBD transmitted this slow scan picture to K4TWJ on 20 meters – very little QRM!

IIBNT transmitted this picture to ON4DN on 20 meters – without QRM.

Word is just in from Franco, I1LCF that the third worldwide Slow Scan Contest, sponsored by *CQ Elettronica* of Italy, will be held Saturday, February 10 and Sunday, February 18, 1973. Full rules will appear soon; however no radical changes from last year's contest are expected . . . should be a real blast.

As slow scan Christmas cards whiz to and fro, may I take this opportunity to wish you a very Merry Christmas

73 . . . Dave, K4TWJ

REPEATER ASSN LAYS BIG EGG

It seems likely that Bob Waters and Gordon Pugh bit off more than they could chew when they tried to expand Gordon's Northeast FM Repeater Association to include everything from Maine to North Carolina and out west to Ohio. It didn't jell.

There is an obvious need for associations of local repeaters, but once you get outside of a couple of hundred miles the repeater groups have no need to get toegther – and they won't.

It seems as if what is really needed is repeater councils for areas of the country – and then perhaps a yearly meeting of all of the repeater councils from all over the country.

When the Northeast Repeater Association , Inc., had its annual meeting in Pennsylvania recently only 33 groups had joined out of about 215 in the association area. And when you consider that most of those had joined on a temporary basis, just to see if the idea was worthwhile, the support for the association seems too slim for survival.

As a result of the fiasco, repeater groups in New England are working up a repeater council for the greater Boston area and a similar plan is afoot in New York City.

NORTHEAST LAYS BOMB

The October 7th meeting of the Northeast Repeater Association drew only a handful of repeater delegates, despite its attempts to attract groups from Maine to North Carolina and out to Ohio. The count was 85 present and only 36 out of the approximately 200 repeater groups in the area signed on even temporarily.

There were several reasons why the interest of repeater groups was so low. One of the most important was that no one could think of any substantial reason for the Association to exist. There were no known benefits to anyone to join or come to meetings.

Another major problem was the size of the area covered by the Association. When an organization stretches out so far that it takes the delegates from each end about six hours to drive to a meeting – and six hours back, there has to be some powerful reason for the organization. There is no reason for this organization other than to have officers, dues and by-laws.

Thirdly, the early history of the Association was unsettling. Many of the repeater groups felt that much of the business was done under the table – and their confidence was not improved at the October meeting when the officers slipped a great big one by everyone, apparently laughing up their sleeves at their cleverness.

Readers who are interested in the exhausting details of the sneaky Association doings would do well to

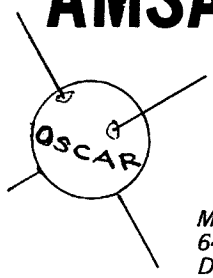
subscribe to the Repeater Bulletin, wherein these shenanigans have been covered at length.

The big one slipped by everyone in October had to do with the Association newsletter. This started out as a typewritten letter for the first two "issues," so the delegates had no way of knowing that anything was afoot when they okayed the sale of copies to anyone wishing to subscribe – it was mentioned that a few people had asked about this. Nor were they alerted when it was asked if anyone had any objection if some advertising was accepted to help defray the cost of publication – who could object to that – every club bulletin has a few ads – right?

Would you expect that these innocent agreements would get you into the publishing business in a big and expensive way? The delegates from the 73 Radio Club sat back and stifled broad smiles as they watched this one slip by. And there in the back of the room was a manufacturer who reportedly had the remaining bones of defunct RPT . . . in his pocket, desperately looking for someone to publish. The post office takes a very black view of manufacturers who try to publish magazines, the last we heard, so some third party is needed.

The way of the splinter ham magazine is a rough one and we wish luck, of sorts, to the Association in their new role.

NEW STANDARD REPEATER



One of the first production models of the new Standard Communications repeaters was set up at the WA1KGO (73 Radio Club) repeater site in lower New Hampshire. Even though the antenna setup was far below the minimum recommended separation, the repeater worked and worked well. What a pleasure to have a repeater you can take out of a box, connect to twelve volts, plug into a couple antennas, and turn on!

When it first arrived and was unwrapped, it was set up in the 73 offices and plugged in, just to see. The result was an instant repeater which covered about ten to fifteen miles – just perfect for any town or small city. The 73 HQ is about 200 feet below the average terrain, as defined by the FCC.

Up on the mountain the Standard repeater was suddenly one of the big boys, permitting amateurs in Boston (80 miles or more) to talk with FMers just about anywhere in that radius. With the proper antenna spacing the rig would work even better and the coverage would probably go out to 100 miles.

The crew at Standard is certainly to be congratulated on putting out a fine little repeater.

AMSAT NEWS

Mike Frye WB8LBP
640 Dauville Dr.
Dayton OH 45429

OSCAR 6 was launched on schedule at exactly 1719 GMT on Sunday, October 15th. THe launch went beautifully and there were few problems. I have picked up the satellite in my area but have so far been unable to transmit through it, possibly because of area conditions.

Monitor CODESTORE on board Oscar 6 and the AMSAT Nets for orbital information. There is also a number you can call in Washington for up to date information (daily between 2300–1200 GMT (202) 386-4483).

AMSAT has a standard reporting form that is available. The form is self explanatory and deals with signal reports, times, and atmospheric conditions. One can be obtained by writing to AMSAT directly, or sending a SASE to me and I will send you a couple of copies.

AMSAT, P.O. Box 27, Washington D.C. 20044.

AMSAT NETS

On Sundays of every week

1200–1300 GMT on 14.280 MHz SSB

1300–1400 GMT on 21.280 MHz SSB

1800–1900 GMT on 14.280 MHz SSB

1900–2000 GMT on 21.280 MHz SSB

On Mondays at 0100 GMT on 1855 MHz SSB

FIGURING ORBIT TIMES

Period of orbit – 115.138 Minutes

Change per orbit – Add 28.81 Degrees

Inclination – 107.76 Degrees

Beacon frequency – 29.45 MHz

Orbit No.	Longitude West	Time GMT*
1	323.97	1824.99
2	352.79	2020.24
3	021.60	2215.48
4	050.41	0010.42
5	079.22	0205.96

*Depends on launch time; add or subtract minutes from 1719 GMT.

OPERATING PROCEDURE

After calculating where the satellite is, the following is a recommended method of using the two-to-ten meter repeater.

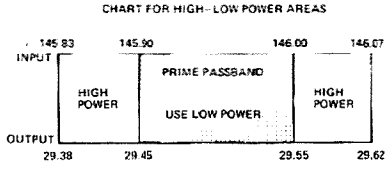
When the satellite comes into range begin listening for the morse code beacon on 29.45 MHz. The beacon sends the message HI . . . . .

After you have located the beacon on 29.45 MHz, tune up the band and begin looking for the signals from the repeater in the 29.45 MHz to 29.55 MHz range.

Before beginning to transmit, a few simple steps should be taken to insure that you do not overload the repeater. If you are going to use high power (greater than 80–100 watts erp) transmit your signal a little off the normal repeater passband.

This will ensure that you do not overload the repeater and cause the agc to go into action. It will also make sure you are not using more of the repeater than your share and you won't blank out weak stations that might be trying to call you.

When transmitting, start by sending a test signal, preferably a string of dots, on this frequency (f_2). Listen for your own signal retransmitted from the satellite on the corresponding ten meter frequency (f_{10}) found from this formula.



$f_{10m} = f_{2m} - 116.45$ MHz $\pm f_{Doppler}$

where $f_{Doppler}$ = +4.5 kHz near beginning of pass

= 0 kHz at middle of pass

= (–) 4.5 kHz near end of pass.

For example a signal transmitted on 145.92 MHz will be retransmitted on 29.47 MHz ± Doppler. This is where you signal will be, if you can hear it, others can too.

OSCAR 6 FACT SHEET

Input frequency range – 145.90 to 145.00 MHz

Output frequency range – 29.45 to 29.55 MHz

Passband is not inverting, in other words upper sideband remains upper sideband and vice versa.

Beacon frequency – 29.45 MHz

Beacon modulation – A-1

Repeater bandwidth – 100 kHz flat

120 kHz at 3-dB down points

150 kHz at 6-dB down points

240 kHz at 10-dB down points

Operating modes SSB and CW are recommended. AM, RTTY and SSTV can be used with less efficiency. FM is not recommended.

Repeater power output – 1 to 1.3 watts CW into half wave dipole

Input sensitivity – Approximately

100 dBm (2 mV/m) for full output. Ground power required – 80–100 watts of effective radiated power produces full output from repeater at maximum range of 2000 miles.
Intermodulation – 20 dB down
AGC
Up to 26 dB gain reduction
0.1 sec. attack time
2.2 sec. release time (highest efficiency with SSB).
Receiving antenna – Dipole can be used but beam is preferable.

WB8LBP

DETROIT ARA ON 220

At the September Board meeting of the Detroit ARA, a proposal was adopted to sponsor a "DARA 22 MHz System" which would include funding to members for constructing transceivers to operate into a repeater. Personal construction was encouraged as part of our educational training, due to the lack of commercial transceivers for this band. The FCC has now released Docket 18803 which allocates the 222-225 part of this band for repeater use. Now it is up to the clubs to follow through and make use of this excellent band which is partically QRM free. This is another area for an excellent autopatch from your car, or a portable system for emergency operations. At least 26 members signed up to work on the project at the last meeting.

73 CRUISE

Plans are firming up for a 73 sponsored Windjammer cruise to leave Antigua on the first of May 1973 for eleven days of sailing and visiting rare Caribbean countries.

Some of the more interesting islands on the route are Dominica, a remote and lush jungle of an island, complete with Caribe indians, a visit to the very French Martinique and a get together with some of the FM7 boys you'd like to work. Your wife will enjoy the shopping and the beauty of the spectacular cliffs and coves along the coast. Captain Bligh's "Breadfruit Isle," St. Vincent, still unknown to the tourists. The beautiful beaches of Grenada – skindiving – fishing. The sandy beaches of Carriacou. Venezuela – will we be able to keep the YV5's from capsizing the boat? – St. Lucia, a combination of British and French – and, don't forget Antigua and the steel drum bands that are world famous.

Will there be a rig set up on the ship? What a foolish question! You'll have the chance to make half the world eat its heart out as you DX. Of course you may prefer to spend your time lying on the deck, soaking up the Caribbean sun – or you may prefer fishing – or skin diving – or visits to islands – to fantastic beaches – or taking photographs for the radio club back home – or you may want to devote your time to eating the great meals.

Whatever you like, you'll be in the company of enthusiastic amateurs where you can swap DX lies and antenna put-downs. After having run two very successful ham tours, we can tell you that traveling with hams is real fun – a whole lot more fun than just any group.

The ship leaves Antigua on May First and returns on May 12th. The weather is guaranteed to be perfect.

The cost, per person, starts at only $290 for the whole trip, including just about everything except the booze. Special cabins are a bit higher – $365, and go up to $410 for the most lavish cabins. First come first served on accomodations.

The yacht is not to be sneezed at, by the way. We will be sailing on the Fantome, formerly Onassis' yacht, which is 262' long – almost as long as a football field. This yacht was built for the Duke of Westminister as a private floating palace. Onassis planned to give the yacht to Prince Ranier and Princess Grace, but it was never delivered. It has private baths, air conditioning and red carpets. There is room for fifty or more on the cruise, which may seem like enough except that almost twenty have alread signed up and the word has hardly been leaked out as yet.

Drop a line to 73, Peterborough, NH 03458 if you want to join this happy group. It will be informal – barefoot – and fun. And do bring the wife. If she has trouble with the sea she should know that this great big boat is very steady and seasickness is virtually unknown on her. If the wife won't go, maybe you have a secretary or good friend who loves the sun and the sea?

MARS

Harry Simpson A4SCF
73 Magazine
Peterborough NH 03458

Harry Simpson A4SCF

People wonder why we keep our ham magazines for years after we receive them. I usually explain that my interests are in a certain sector of electronics at any given time, and an article that was only of passing interest in November, 1970 might be of supreme importance in November, 1975!

This MARS Column is a distinct example – the first effort, printed many months ago, gave an address for Navy MARS that was incorrect, although it was the address printed on the MARS brochure. The same article used my home address, rather than the 73 address in Peterborough. I am still receiving mail addressed to my home, complaining about the inability to contact Navy MARS at the address given! Come to think about it – you are not alone! In spite of numerous phone calls and letters asking for information, and asking that I be placed on the mailing list for Navy MARS publications, I have yet to receive a single word from them! *Quien sabe?* Perhaps that organization is only a figment of some overworked imagination!

Obviously I am being facetious. There *is* a Navy-Marine Corps MARS and it is quite active, its members numbering into the thousands of public-spirited amateurs. It's just that you have to be a member of Navy MARS in order to find out how to join! For the record, here's the latest address I have: *Chief, Navy-Marine Corps MARS, 4401 Massachusetts Ave., N.W., Washington DC 20390, Mail Stop 394.*

To cut down on the workload, let's do it this way – if you would like to join *Army MARS*, and would like further information on this splendid program, write me in care of 73 Magazine. I will answer your questions, and also pass along the name and address of an Army MARS member in *your* area who can tell you about the program on a local basis. On the other hand, if you would prefer another service, I suggest that you contact them directly, since I have already told you all I know about them. For several months I have been sending out an average of two hundred letters per month in answer to your queries, and at my own expense. To the ten hams who included SASE's with their queries – I am grateful.

This article is being written while on vacation in the southeast – at the moment, Pensacola – and the most amazing thing that occurs on each vacation, is the realization of the broadening scope of 2 meter communications! In the Third U.S. Army MARS area – North and South Carolina, Georgia, Florida, Tennessee, Alabama and Mississippi – there are over *thirty* MARS repeaters, covering most of the very large area! Several other machines are being readied, and pretty soon you'll have to turn off your transceiver to get away from it all!

A word about prefixes: In Third Army area, W is changed to A, K becomes AA, WA is changed to AD, WN and WB are changed to AL. KP4 and KV4 are *both* changed to AE6 (a paradox that might cause some trouble in the event we sign up both KP4AA and KV4AA . . . they would *both* be assigned the call AE6AA!).

Listen any evening on 4001.5, 4015, 4020, 4025, 4030 and 4035 kHz for our typical operations, and then write for more details. We'd like to have you!

See you next month . . . *A4SCF*

DEEG DIGS NEW HAMPSHIRE

Here is Fred Deeg K6AEH, the sales manager of Standard Communications, making a nice DX repeater contact from the top of Pack Monadnock, the site of the WA1KGO repeater. The antenna on the side of the fire tower behind Fred is the receiving antenna for KGO – height 2300 feet above sea level and radio horizon about one hundred miles. It took one of the worst muggy spells in the history of New Hampshire to get Fred on his way back to "sunny" California.

The new Standard repeater is now set up in the same tower and providing fine FM coverage for a good deal of New England.

And what hand unit is Fred using? A Standard, of course!

73 FILES PETITIONS

There have been six petitions filed by 73 on the new repeater regulations so far – with more in the offing. The new rules have some advantages, to be sure, but the disadvantages seem to overshadow them and 73 has filed with the FCC on the sharpest points of objection.

For instance there is the matter of the prohibition of cross banding of repeaters. There has been no example known to the 73 staff of any serious problems arising from this practice. To the contrary, those few repeaters which have this function have been most popular and have provided a valuable service interconnecting the groups using one band with those using another.

The FCC, the Amateur Division of the FCC and the Commissioners need to be reminded that this is amateur radio – it is a hobby – and that we need latitude to experiment and develop systems of communications. The Commission deals 99% or more of the time with commercial users and perhaps this has biased their judgment for the new regulations seem more fitted to commercial operations than amateur.

If the Commission would restrain itself and provide regulations only when there is a clearly demonstrated need for them – only when amateurs have demonstrated that they are unable to manage their own affairs, then the growth and technical development of the hobby could move forward relatively unimpeded. The fact is that even though we had no regulations covering repeaters, we had no real need for them. One would wish that the Commission would ignore the requests of amateurs who need the security blanket of exact and detailed rules.

Repeaters have shown, more than any other amateur groups, that they are able to regulate themselves. The cooperation has been epochal. Interference has been kept to a minimum – intergroup hassles have been ironed out just about everywhere – jamming has been coped with – frequencies have been coordinated – standards have been agreed upon and all but a few really hardheaded repeater groups have fallen into line.

In the face of this truly remarkable progres, the FCC repeater rules are an insensitive slap in the face. We have little for which to thank the few amateurs who initiated this action several years ago. Perhaps it is only fitting that Gordon Pugh W2GHR is one of the hardest hit by the new regs.

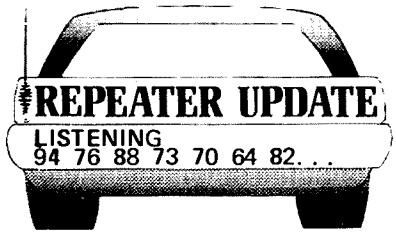
1973 Friendly Firebird QSO Party

Date: From January 6, 1973 at 1800 GMT to January 7, 1973 at 1800 GMT.

Group: General Motor's World Wide Employees and Retirees.

Call: "CQ Firebird" on phone or "CQ FB" on CW.

Exhange: Signal report, State (or country) and Handle plus Firebird members will send a four-digit number corresponding to his General Motors Operating Unit (i.e., "0101" for AC Spark Plug Division). Send SASE to W9MDW for cross reference sheet.



Scoring: One point per QSO. Work each station only once regardless of frequency.

Multiplier: Number of different operating unit numbers.

Total Score: Total QSO points times total operating unit numbers.

Frequency: Any frequency, but suggest 3.985, 7.285, 14.285, 21.385, 28.785, 50.520, 145.440 MHz and near bottom of each novice band.

Logs: Send to Dick McClain W9MDW, 1613 Cherry Hill Lane, Kokoma, Indiana, 46901 by February 15, 1973.

UPDATES REQUESTED

The next printing of the full list of all repeaters in the world is scheduled for the April issue of 73. It would be appreciated if every repeater group would send in at least a card giving all possible repeater information for your area – including the frequencies of your repeater, the town it is located in, a mailing address for correspondence – a list of all other repeaters in your area – calls – towns of location and channels used. It is much easier to make up a list with too much information than too little.

The FM Repeater Atlas is updated three times a year, so it is important that all changes in repeater channels, calls, or location be reported as soon as they are known. Thousands of amateurs depend upon this atlas to help them to keep in contact with repeaters as they travel – don't disappoint them by letting your listing or that for your area get behind.

SAROC

Disappointment

The FM program at Saroc last year left a lot to be desired so I offered to set up an FM Symposium for this convention that would hopefully be better. Along about the time I had things nearly organized, I got a call from Leonard Norman, the chap who runs the convention – someone had threatened not to exhibit if I ran the FM program – it was all off, he would set up his own FM program.

Was it an advertiser who has been banned from the pages of 73 or a fellow publisher in a panic after seeing the November 73? Unless I have some very secret enemies, I can only think of about three possible people who could have pulled that one.

Whoever it was saved me a lot of time and expense. They also cut my enthusiasm for Saroc by about 98%. If it weren't for the chance to sit and talk with a whole lot of good old friends, I would pass it up. Las Vegas is a gaudy, expensive, plastic bore. Sour grapes – right?

Wayne

50 MHz BAND

Bill Turner WAØABI
5 Chestnut Court
St. Peters MO 63376

K8LEE reports an opening to South America on the 19th of September around 2240 Z. A few minutes earlier, weak signals had been heard from Florida (W4GDS) and these continued intermittently during the approximately one hour the band was open. Wayne, WA8PEB and K4JBV worked LU8AHW (CW and SSB), LU3EX and HK3OK (AM) during this period. Tapes played over the telephone confirm the excellent signals received. There was apparently no connection between the two openings. Florida was weak E while South America was rather strong TE, peaking at times to S9. Wayne reports these signals were also heard in Indiana but were rather faint there. Did anyone else manage to work this opening?

Jim, K7ZFG/6, passes along some further information relating to the carrier null instability sometimes experienced with the Swan 250. "In mine, the carrier balanced with the start of transmission, drifting to near full carrier after about a minute. Eventually the control was so far off center that the carrier couldn't be balanced even at the start of transmission. My solution was to replace R1305 and R1309 with 47K, 1 watt resistors and replace R1306 and R1310 with 100K, 1 watt resistors. After this, the carrier balanced in the center as it did when new, and hasn't caused trouble since . . . it might be advisable to use 2 watt units for additional stability and also replace R1307 with a 1 watt resistor."

I might add that it is not uncommon to find a new 7360 which will not balance with the original resistors; often it is inconvenient or impossible to try several tubes in order to find one which will work properly. The solution is to reduce the fixed resistance on one side of the circuit and increase it a like amount on the opposite side. The unbalance caused will correct the unbalance within the tube. Decrease the resistance on the side to which the null pot must be turned to come close to a null. The amount of resistance change is determined by the unbalance in the tube. Try 20 0/0 for starters. This change may also be used to temporarily cure the problem in a rig with an old tube which has become unbalanced with age. This will allow you to stay on the air while a new tube is being obtained.

K5MTK writes from Fort Worth to say that he has found the problem in his Globe Hi-Bander and will shortly be back on the air – this time with a new 5 element beam. Elmer also passes along the information that the Arlington Radio Club meets Monday evening at 2000 local on 50.8 and the Tarrant County Six Meter Emergency Net meets every night at 2100 on 50.7.

Lowell, WB4WNV, asks "Do you know of any net type operations on 6 meters in the north Georgia area? How about even any individual stations that operate regularly?" I don't know of any active nets or individuals in your area. Georgia has always been rare in this area either because of the distance or lack of activity. I have always assumed it to be the latter. Perhaps one of our readers will offer your group assistance in getting on the air, and let us know about the local activity, too.

Peter, WA6HXM, writes to say that he and WB6ECD have both worked and confirmed contacts with VE1ASJ. There seems to have been some confusion about the comment in the

October column to the effect that Andy had not made a California contact. This comment was in reference to the July 18-19 DXpedition to Prince Edward Island only, not the season as a whole.

The "K2OAW" frequency counter has been in operation for over a month at this writing . . . it works perfectly. I would highly recommend it to anyone in need of a frequency measuring device. The next project for this station will be an outboard mixer to combine the vfo, carrier oscillator and heterodyne oscillator signals and allow continuous monitoring of the receive and transmit frequency. First thoughts are for perhaps a pair of 40673's – comments from those who have accomplished this already, would be appreciated.

The December openings won't be far off by the time you read this – is your rig in good shape and ready for the "Second Season?"

WAØABI

NEW CERTIFICATE THREATENED

It obviously had to come to this: a certificate for making one contact! The Navassa DXpedition crew of KC4DX have announced a certificate which is available to any operator who managed to get through the tremendous pileups and make a contact.

It is hard to believe that anything as nice as this is available for only one dollar! Why, that barely covers the postage and handling, not to mention having a little left over for the Atlanta club to put toward another expedition.

If you are one of the few lucky and persistent DXers who did contact KC4DX all you have to do to have this outstanding award is send a confirmation of the contact to His Eminence Chaz Cone, Box 11555, Atlanta GA 30305, include one dollar (minimum – no maximum has been set, but the members of the DXpedition do go around on bended knee a lot when hints of donations are made) – why not make it $2 – you'd spend that on a movie.

WITH THE FCC

MORE REPEATER RULES

Applications filed after October 17, 1972 – All amateur applications filed on or after October 17, 1972, must comply with the new rules adopted in Docket No. 18803.

Existing stations – A station operating as a repeater station, and/or one authorized for remote control, whose license was granted as a result of an application filed prior to October 17, 1972, should comply with the new rules adopted in Docket 18803 to the extent possible after that date, but must fully comply by no later than June 30, 1973. Applications for such stations received prior to October 17, 1972, will only be granted authorization for operation for the balance of the original license term without payment of additional filing fees. If a renewal or additional privileges are requested, normal filing fees will be required. Applications for station license modification filed after April 30, 1973, may not be processed in time to permit continuity of operation.

Waivers – The granting of waiver requests except under the most exigent circumstances are not contemplated.

Intra-community – The Report and Order and the rules speak of limiting repeater station coverage to intra-community amateur radiocommunications. In consonance with the rules limiting to two the number of repeater stations operating in tandem, intra-community is considered the maximum area covered by such a network.

Call signs – Beginning October 17, 1972, a license issued for a repeater station will authorize a call sign having the prefix WR followed by the number of the applicable FCC district. The suffix will be three letters assigned systematically starting with AAA.

AND MORE...

Rules amended to exclude business and commercial third party traffic from amateur operation; new rules proposed to permit limited compensation and to modify logging requirements.

Part 97 of the Rules has been

amended by the Commission to prohibit amateur operators from transmitting messages over amateur radio stations for business and commercial parties (Docket 19245). (Third party traffic is defined as amateur radiocommunication by or under the supervision of the control operator at an amateur radio station to another amateur radio station on behalf of any one other than the control operator.)

In a separate but related action, the Commission issued a Notice of Proposed Rule Making concerning possible limited compensation for amateur club station control operators and possible relaxation of the logging requirement for third party communications.

In a Notice of Inquiry released May 5, 1971, the Commission requested comments on whether any restriction on the use of amateur radio stations by non-amateur organizations was needed, and if so what those restrictions should be. The inquiry resulted from petitions to change the present rule (Section 97.39) which prohibits certain organizations from obtaining amateur station licenses or having an amateur operator use his station in their behalf.

The Commission said that radio communications, the sole purpose of which was to facilitate business and commercial traffic, was not in keeping with the intended purpose of the Amateur Service, and should not be allowed except for emergency communication. Amateur licenses will thus not be issued to schools, companies, corporations, associations or other organizations. The Commission explained that to prohibit third party traffic entirely would tend to stifle one of the basic purposes of the Amateur Radio Service, which is to provide a voluntary non-commercial radio service, but to allow all third party communications would tend to cause increased congestion in the amateur bands.

The rules become effective December 1, 1972.

The provisions of Sections 97.114(b) and 97.112 prohibit the American Radio Relay League's long standing practice of providing compensation to the control operators of station W1AW, which transmits code practice and informational bulletins of particular significance to amateur licensees. In a Notice, however, the Commission proposed rules which would allow this compensation and granted a waiver of the Rules to W1AW to permit it to continue operation pending final action on the Notice. It said that other club stations providing similar services may also apply for waivers. The Commission invited comments on whether to allow any *bona fide* amateur organization to operate a station and provide reasonable compensation to the control operator when the station transmits material solely related to the Amateur Radio Service or whether to create a new class of amateur station.

Comments were also invited on the usefulness of the Section 97.103(b)(3) of the Rules, which requires that an amateur radio station log include a notation of third party messages sent or received, including names of all participants and a brief description of the message content.

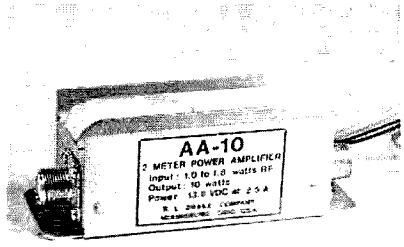
Comments are due by December 20, 1972, by Report and Order and Notice of Proposed Rule Making. Commissioners Burch (Chairman), Robert E. Lee, H. Rex Lee, Wiley and Hooks with Commissioner Johnson dissenting.

AMERICAN AMATEURS MAY EXCHANGE SATELLITE DATA WITH GERMAN AMATEURS

The FCC issued a Public Notice on the above on October 5, 1972. The text follows:

Information has been received by the Commission that the Bundes Post of the Federal Republic of Germany has no objection to the exchange of third party traffic with German amateurs relating to an exchange of technical data in connection with the launch of OSCAR 6 amateur satellite and throughout its orbit period.

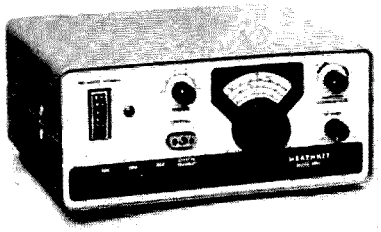
Such third party traffic may be directed to other amateur operators in Germany only concerning the subject satellite operation. There is no change in the status of the general conditions relative to normal third party traffic between the Federal Republic of Germany and the United States. The Commission concurs, therefore, with the limited relaxation of third party traffic concerning OSCAR 6 and has no objections to Amaerican amateur operators engaging in such exchanges of information!



How many OM's recognize Rod VK3CR?

NEW PRODUCTS

10W AMPLIFIER FOR THE TR-22

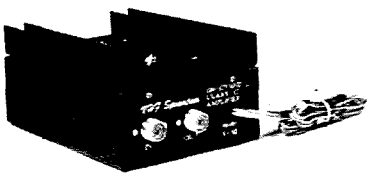


The R.L. Drake Company has finally expanded their FM line with a small piece of gear that will no doubt increase the happiness of a lot of already happy FMers. The specific unit is the AA-10 FM amplifier designed to be driven by the one watt available from a TR-22. Rated at 10 watts output, it will give you that extra punch that is lacking when just using the transceiver. While 10 watts alone is not exactly a high power figure compared to some of the mobiles running around today, the 10 dB gain available from this amplifier is bound to make a big difference in the number of repeaters that you can get through to.

Inside the case nestles a TRW PT4544 transistor mounted on the neatest circuit board you've ever seen. The T/R switching is all automatic through the use of diodes . . . no relays to clutter up things. The instruction book is very good and identifies each part along with complete directions on how to retune the unit if the need arises. I tried touching up the output a bit but was thoroughly disappointed. The Drake people had the audacity to sell us a perfect product! All the coils were exactly pretuned at the factory. There's just no fun in it anymore . . .

The amplifier is rated to operate with inputs between 1 and 1.8 watts. Feeding approximately 2/3 of a watt into it still produced a respectable output of 8 watts. With its compact size, a neat little transceiver could be wired up using those small commercial receiver and transmitter modules. Mount the boards and crystals in an attractive little case and mount the AA-10 on the rear. Right outside where it looks the best. the AA-10 sells for $49.95. Also available is a matching ac supply, the AC-10, for $39.95. From *R. L. Drake Co., Miamisburg OH.*

QRP TRANSCEIVER



Heathkit has announced its entry into the QRP transceiver field with a new three band CW rig. The HW-7 is designed for 40, 20 and 15 meters with vfo or crystal controlled operation on all three bands. The receiver is claimed to have better than 1 μV sensitivity, which is pretty good considering that it is not a superhet but a direct conversion Synchrodyne. The transmitter input power is 3W on 40, 2.5W on 20 and 2W on 15 meters. While this is nowhere near enough power to leisurely earn a DX certificate (at home . . . in your spare time) you would be amazed at the contacts possible with only a few watts. In October WB2WYO stopped up at 73 while on vacation and I got a look at his nearly full log book. He runs 2W from a rig inside his camper to a piece of tuned wire strung out to the nearest tree. With this simple setup he manages to work across the country with 579 signal reports!

The best features of low power operation are portability and freedom from external power sources . . . ooops, don't forget fun! The HW-7 is designed to operate from an external ac supply or 12V batteries. Just plug in a fresh set and disappear into the wilderness for a while. What could be more appealing than operating portable VE8 from the banks of a wild river in Canada?

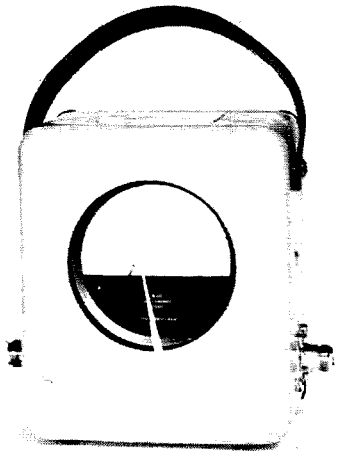
The HW-7 features push button band switching, sidetone and a relative output meter for tuning convenience. It sells for S69.95 from *Heath Company, Benton Harbor MI 49022.*

50W FM AMP

VHF Specialists offer a new Model 5-50 two meter amplifier for the serious FMer. Featuring two Balanced Emitter Transistors, it exhibits extreme sensitivity and tolerance to VSWR changes. No need to worry about damage if your coax is open or shorted. Although the input is rated at 5 watts for an output of 50, the high gain input transistor will amplify only one paltry watt enough to drive the output stage to 40 watts output! With such a wide range of input powers that can drive this amplifier to a respectable output, the unit makes an ideal "universal black box" for FM work. The only possible complication would be the failure of the relay transistor to get enough rectified rf under low power conditions. No real problem though . . . for the circuit manual gives complete instructions on how to compensate for this by trimmer adjustment.

It is amazing when you think about a seemingly small thing like package design in amateur equipment . . . a lot of manufacturers mount their circuit boards in a metal box and just drill holes for the power leads and connectors somewhere near the place of connection to the boards. Whoever packaged this little amp had some idea of what most of us would be doing with it – tucking it up out of the way somewhere. Notice how the power leads and both connectors are mounted on the same side of the case. With its small size of only 5x7x3, one should have no mounting problems. $89.95 from *VHF Specialists, P.O. Box 167, Vienna VA 22180.*

NEW HEATH SCANNER



The Heathkit GR-110 Scanning Monitor brings you up to eight crystal frequencies to cover the active VHF bands in your particular locality.

The GR-110 can be tuned in either a manual or automatic mode. To tune manually, you simply depress the front panel "manual" switch to step to any desired controlled channel 0 through 7, which is read out by the digital channel indicator for fast identification.

In the automatic mode, the monitor scans rapidly through all eight channels and locks on to the first one that starts a transmission. It stays locked on that channel as long as the transmission continues. If transmission stops, the monitor will release the channels after four seconds and resume scanning. To bypass channels during the scan, front panel pushbuttons let you lock out any channels you desire. A priority channel is also provided which takes precedence over all other channels. The monitor automatically locks on to this channel whenever a station is transmitting even though it was already locked on another channel. The scanning monitor works equally well as a home or mobile unit. Line cords are provided for 120V ac or 12V dc battery power. A price of $119.95 and four evenings of your time will get you in on all the repeater action. *Heath Company, Benton Harbor, Michigan 49022.*

NEW BIRD WATTMETER

The new model 4342 Dual Wattmeter-VSWR Monitor displays the three prime rf transmission measurements at once on a single meter face: Forward and reflected power are indicated by individual pointers and VSWR is monitored on a third scale from the intersection of the two power pointers.

Unlike most VSWR meters, the model 4342 does not require *any* adjustments to full scale deflection, or any switching before VSWR readings can be taken. The entire set of three transmission parameters is read out simultaneously during normal rf operations or during maintenance adjustment procedures.

Power and frequency range of the new Bird Dual Wattmeter-VSWR Monitor depend on two plug-in elements selected from more than eighty choices available with the company's popular THRULINE Model 43. Full scale power levels at ±5% accuracy range from 10 to 5000 watts for reflected, in discrete frequency

THE AFSA IV SSTV ANALYZER

Slow Scan TV has three key frequencies; 1200, 1500, and 2300 Hz. When receiving, the most critical is 1200 Hz, the sync frequency. When transmitting, the 1500 to 2300 Hz range is the critical area of concern. Here is how to build a unit which will solve both tuning problems.

The ideal method to find out what is happening to an SSTV signal would be to instantaneously analyze every Hertz generated and comparatively display them on an oscilloscope. The limits would be seen, plus gray scale, gamma correction, and transients. As a bonus, RTTY can also be displayed and instantaneous shifting errors analyzed. Complicated? Nope. $10 worth of IC's and transistors should do it, along with a surplus 'scope tube.

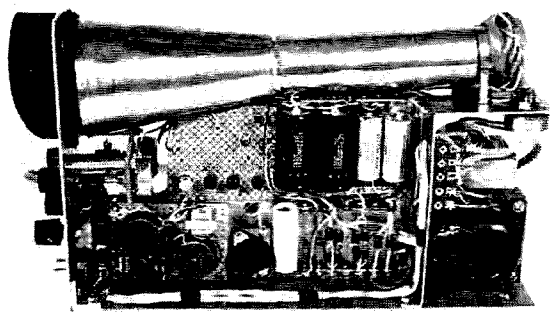
Theory

This unit measures the time the positive going portion of each cycle takes. For each Hertz, an oscilloscope sweep is triggered when the incoming signal crosses 0 and starts positive, and a vertical pulse is generated 180 degrees later when the signal again crosses 0 and starts negative. The trace is begun at the right side of the screen near the bottom and continues at a linear, semi-logarithmic or

AFSA as built by K7YZZ. Semi-logarithmic sweep.

logarithmic (your choice) rate towards the left near the bottom. The higher the frequency, the shorter time the Hertz will take, and the pulse will appear closer to the right side of the screen; whereas a lower frequency will approach the left side of the screen the closer it approaches the sweep frequency.

Three previous versions have been built and used by many of the active SSTV'ers over the last two years. AFSA IV uses an active high pass filter/limiter with a gain of 500, and a cutoff of 1200 cps with a rolloff of 40 dB per octave. Following this is a non-critical NPN transistor which acts as an inverting, clipping and interfacing stage to drive two TTL singleshots.



Positive going portions of the incoming frequencies trigger the delayer singleshot. Since the highest frequency of SSTV is 2300 Hz, the pulse at the end of the sweep would always take over 200 microseconds to occur, and if the sweep was triggered at the beginning there would be a considerable amount of wasted sweep. However, by using a variable singleshot delayer, the sweep may be initiated just before the expected 2300 Hz pulse.

The sweep op amp has a circuit which allows the user to select any rate and linearity desired by varying the ratio of two potentiometers, R3 and R4. The ramp linearity may be anything from exponential through linear (sawtooth) to logarithmic. Feedback is taken from the emitter of the high voltage output transistor to both improve the resulting ramp shape and the stability. Previous designs suffered from horizontal drift, but this one stays within 10 Hz from cold to very hot.

Back at the interfacing transistor, when the positive half of the Hertz is done, the vertical pulse generating singleshot is triggered. Size and clarity of the pulse can be varied with R1. Following this IC is a high voltage transistor which drives one 'scope vertical plate.

Construction

At the present time, I don't know of two identical AFSA's circuitwise, much less layoutwise. The 'scope tube may vary from 2 to 5 in., but most prefer the 3 in. size. A 3HP1

AFSA of K7YZZ. Inside right view. Utilized AFSA II circuitry. (Toroids instead of active filter, RTL instead of TTL Singleshots, not drift compensated. Used more parts.)

would be nice since it has a rectangular face 3 in. wide by 1 in. high. Some AFSA's are built as a separate unit, while I prefer to include it on the same chassis with my monitor.

The electronics are very non-critical and similar IC's and transistors may be interchanged with little effect. The ones specified are the simplest and cheapest that I had available. The layout should be in a rather straightforward manner to prevent feedback around the input/limiter stage, but other than that just keep the adjustment pots accessible. My power supplies are part of the monitor, but any reasonably well regulated design should work fine.

If you are building this unit strictly for RTTY usage on the standard mark and space frequencies, lower the active filter resistors from 9.1K to 5.6K and from 4.7 MΩ to 2.5 MΩ. This will then raise the cutoff frequency to around 2000 Hz.

Tuneup

At this point you have to make a decision on what you would like to do with AFSA. If you build AFSA IV as given, then use Table I or Table II to initially set the adjustments. Note that you have the choice of semi-exponential, linear, semi-logarithmic, or logarithmic.

My SSTV choice is semi-logarithmic. This gives an expanded portion around the sync frequency range of 1200 to 1500, but still doesn't crowd the video range of 1500 to 2300 too badly. The linear sweep settings

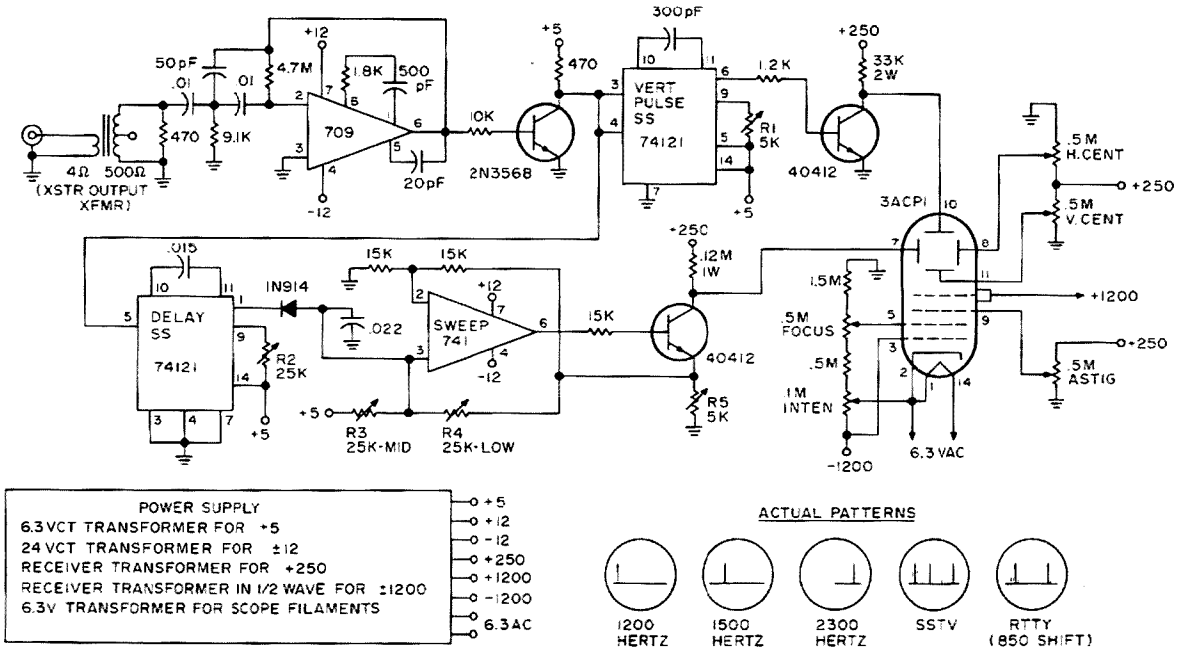


Fig. 1. Schematic diagram of the AFSA IV SSTV analyzer.

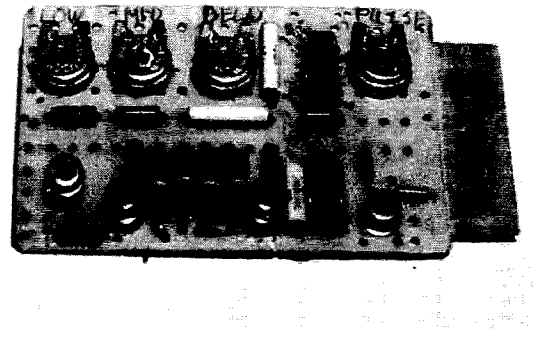


will give a logarithmic display of frequency which seems to crowd the high end. It does give a very good indication of unstable sync pulse frequencies and transients occurring in the range between 1200 and 1500. The logarithmic sweep will produce a linear display of frequency (e.g. 1200–1300 Hz will be just as much separated as 2200–2300 Hz). This display is good for measuring and interpolating frequency departures from the standards.

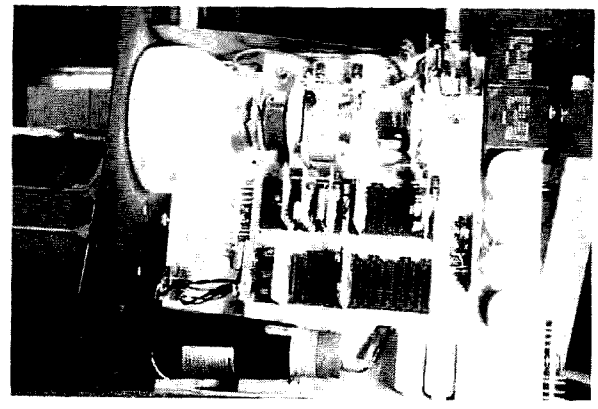
For RTTY use, logarithmic sweep will enable straddle tuning, but it tends to make 170 Hz shift signals difficult to tune due to the small separation in frequency. Linear sweep produces a nice picture, and a semi-exponential sweep would give even better separation to the narrow shift. However, straddle tuning becomes quite difficult unless fine calibrations are made when calibrating the scope frequencies with linear or semi-exponential shift.

I set up the sweep for SSTV use by using an audio generator at 1500 Hz and adjust the sweep width (R5), horizontal centering, and vertical centering for a horizontal line that just sweeps the entire face of the 'scope about 1/3 up from the bottom. The pulse should appear somewhere around the center of the screen. Adjust the pulse width control so that the pulse is a sharp line extending up from the base line to about 1/3 down from the top of the screen.

Next I set the generator to about 2500 Hz and adjust the delay (R2) to get the pulse just inside the right edge of the screen. After this low sweep (R4) is adjusted to that 1100 Hz is just inside the left edge of the screen. Middle sweep (R3) is adjusted so that 1750 Hz for logarithmic, 1600 Hz for semi-logarithmic, or 1500 Hz for linear occurs in the middle of the screen.

For RTTY, I adjust sweep width (R5) using 2400 Hz. Adjust delay (R2) using 3100 Hz. Adjust low (R4) for 2000 Hz. Adjust middle (R3) so that 2400 for semi-

AFSA III Circuit card of WØLMD. Except for some slight changes, identical to AFSA IV card. Input stage on another card in monitor.



exponential, 2450 for linear or 2550 for logarithmic occurs in the middle of the screen.

Since the adjustments interact, it is necessary to go through the adjustments several times. A 'scope attached to the output of the HV transistor will show the effect of the changing ratio of R3 to R4.

Using

After tuning, swing the audio oscillator through the SSTV or RTTY range. You will notice that the pip will exactly follow the audio oscillator's output frequency. You can now calibrate the screen using a felt tip pen, tape, or decals. For SSTV, calibrate 1200, 1500 and 2300 Hz with long lines. Then calibrate 1300, 1400, 1700, 1900, and 2100 Hz with shorter lines. For RTTY, I place long lines at 2125, 2295 and 2975 Hz. Shorter indications are placed at the crossover points of my TU at 2210 and 2550 Hz.

Now hook up AFSA to an SSTV signal, preferably your own in closed loop at this point. You should notice a considerable amount of "grass" in the 1500 to 2300 Hz region corresponding to the video information. At 1200 Hz there should be a faint pip, brightening on the vertical sync pulse. Now, for a bit of fine reading. You will notice faint pips in the "dead area" between 1200 and 1500. These are transients caused by sync time switching in the middle of a Hertz. Some stations use severe clipping to achieve a contrasty picture. When looking at these on AFSA a world of transients appears. This shows why these pictures sync so poorly. AFSA shows that very few stations use the full video range. Most stations crowd the white frequency (2300), the black frequency (1500), or both, which results in a lack of gray scale (naturalness). The correct picture as displayed on AFSA IV will have few transients in the "dead area," no dominant bright lines at 1500 and 2300, but a lot of action in between.

Top view of monitor and AFSA IV. AFSA IV card is immediately above 3ACP1 tube socket. Monitor is IC magnetically deflected using a 7 in. tube.

When QRM increases so that the gray scale is not so important, contrast should be increased so that 1500 and 2300 begin to show brighter lines, but not so much that transients appear in the "dead area." Note that your 1200 Hz horizontal sync pulses dance around a bit. Mine are stable within 20 Hz of 1200, but some stations may wobble up to 70 Hz. And that hurts! (Pun intended.)

Those stations with excess transients and sync wobble are seldom copyable except under ideal conditions. I believe the sync wobble is caused by lack of symmetry in the

Table I – SSTV

	R1 (Pulse)	R2 (Delay)	R3 (Mid)	R4 (Low)	R5 (Width)
Linear	2K	18K	20K	13K	4K
Semi-log	2K	18K	10K	22K	4K
Log	2K	18K	5K	25K	4K

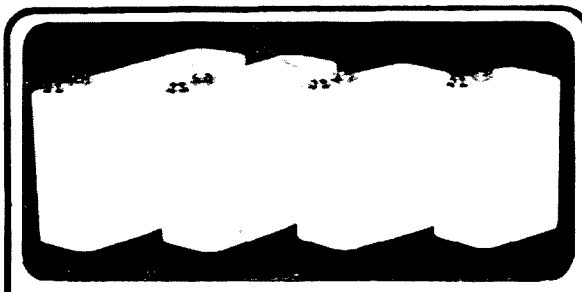
Table II – RTTY

	R1 (Pulse)	R2 (Delay)	R3 (Mid)	R4 (Low	R5 (Width)
Semi-exp.	1.5K	15K	25K	3K	4K
Linear	1.5K	15K	7K	4.5K	4K
Log	1.5K	15K	2.5K	9K	4K

multivibrator section of the camera, too sharp of a filter following the MV, or frequency cutoff in the transmitter or receiver.

With RTTY, a similar situation exists. AFSA should just show bright lines at the mark and space frequencies with less than 25 Hz wobble, and a slight amount of switching transients in the "dead area." Few RTTY stations are this clean. Most show considerable "chirp" caused by dirty and/or corroded contacts, very poor AFSK units and low pass filters, and passband troubles in transmitter or receiver. After seeing all of the "crud" transmitted, it's quite a tribute to the machine. It copies anything. As with SSTV, this is why some stations are wiped out by the slightest interference.

Parting Pips



1. A 709 & 741 in the metal can have a tab next to pin 8.
2. The 74121, and 709 & 741 in the dual in line case have an indentation on the top between pin 1 & 14 (8).
3. Polypaks, Allied & Newark handle most of the parts.
4. The transmitter inverter can be any switching NPN.
5. The output High Voltage Transmitters may be any capable of at least 250V and a few megahertz.
6. AFSA requires a noise and QRM free signal for best frequency discrimination. Avoid giving reports under marginal conditions.
6. A future improvement that I am going to add is a blanking circuit so that only a dim horizontal line is visible compared to the vertical pips. The vertical pips will then also provide an unblanking pulse. For a method of blanking, refer to *73*, June '66, p.15.
8. A dual trace 'scope tube should be considered. On SSTV, use a 5 in. dual gun P7. Use a yellow filter for the SSTV monitor and a blue filter for an AFSA display at the top or bottom of the screen. For RTTY use a dual gun tube with a medium or fast phosphor decay and build a "flipping line" display at the top and AFSA IV exponentially swept at the bottom.

SINGLE CONVERSION TWO METER FM RECEIVER

Four transistors and an IC

The following is a description of a build-it-yourself two meter FM receiver using two new components to achieve a single conversion job for narrow-band FM amateur use. It produces plenty of good, clean af from a total transmitter deviation of 10 kHz.

The Trend to Multi-Function IC's

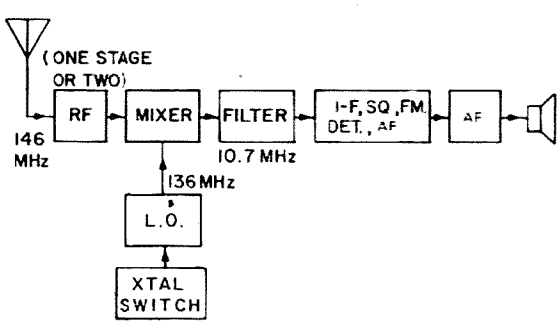
Once again the broadcast industry has created a component of considerable interest and utility to amateurs. This is the RCA 3089E chip, in a plastic 14 pin case, ¾ x ¼ x 1/8 in., containing some 63 transistors, 30 resistors, and 14 diodes. The major block functions and transistor count in each follows: i-f amplifier (22); quadrature FM detector (10); audio preamp (13); level detector and meter circuit (15); squelch drive (4); bias supplies (10); agc buffer (1). The price of all this? . . . $3.63.

The Trend to Ceramic or Crystal Filters

This has led to a unit ¾ long x 3/8 in. thick, in a two pin metal case, which furnishes all the selectivity needed for narrow-band FM in the i-f section. This little tin can takes the place of quite a number of tuneable coils and stays right there on frequency at 10.7 MHz. You can't change it even if you want to. It works!

Receiver Block Diagram

Figure 1 shows how simple it all is (?). Here we are back again with a single conversion, after decades of double and triple conversion jobs. The individual circuits of each block, the rf, mixer, L.O., i-f and af, are all shown in detail, with two-terminal connections between each block, so no overall schematic is needed. Many pages could be written on the philosophy of design, but this is a construction article, so here we go right into the thick of it.



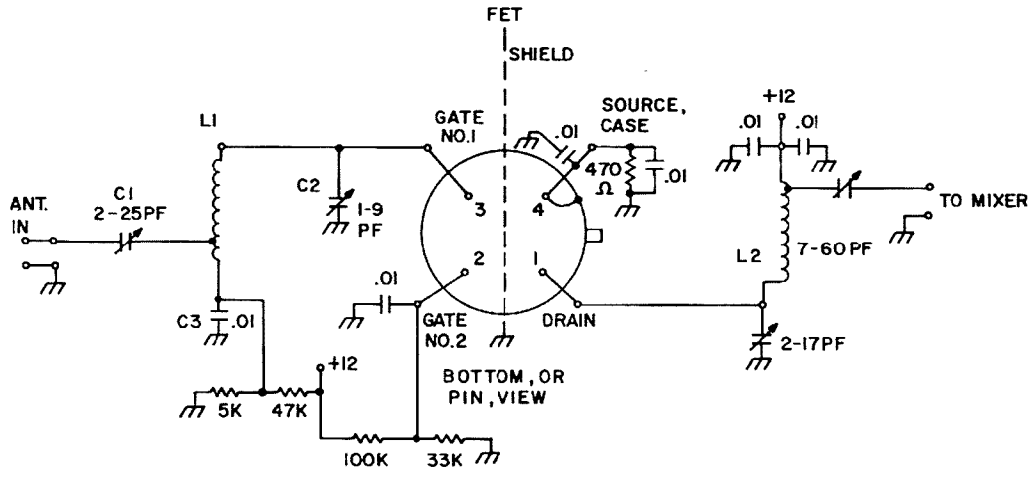


Fig. 1. Block diagram of 2m FM receiver.

The Tuner

Figure 2 shows the rf stage schematic using the "insulated protected dual gate metallic oxide semiconductor field effect transistor" (to give its true full name). You can treat these little gems almost like a tube. The "almost" refers to the need for fixed bias as well as self bias if you want maximum gain as well as anti-spurious, anti-inter-

Fig. 2. FET rf stage.

modulation, and anti-overload characteristics all in one tiny package. These features are aided by *separate* bias adjustments for each of the two gates. While this is optional and not critical, it helps.

There is one place in the rf stage you must pay attention to in order to allow full gain without neutralization. You must use the shortest possible leads and low inductance capacitors (preferably no leads at all) on the source bypassing. This is the transistor element similar to a cathode or an emitter. If you don't, it will oscillate when lightly loaded. Fortunately gate No. 2 is so arranged internally that it acts as a shield, somewhat in the manner of the screen grid of a tube. Use short lead bypassing also, although it is not as critical as the source.

With these precautions the FET stage will give high gain and low noise without neutralization. One rf stage is shown, but another can be used for maximum sensitivity and minimum noise figure.

Mixer

This is another dual gate job, with the nice feature of having the signal on one gate and the L.O. on gate No. 2, just like two grids in the old mixer tubes. Here is where careful adjustment of *both* fixed bias voltages will pay off in rejection of spurious, intermodulation, and overloading. You can leave it as is in the schematic, or make checks yourself if special conditions occur at your location. One thing I found (there are always things to trip you up which are not "in the book") that you should watch for, is oscillation due to the fixed bias on gate No. 2 being too high.

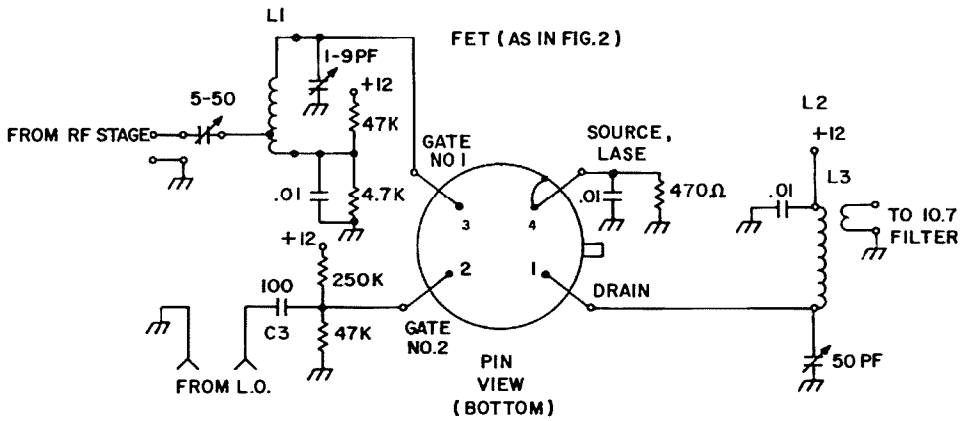
Testing of Front Ends

In order to get everything right, promote smooth tuning and operation, determine best component values, whether or not any component or voltage is critical, and to find out in general what makes a given circuit tick, I use a broad-band, low sensitivity i-f for the first go around. With the rf stage in front of the mixer this was simply an AM detector tuned to 10.7 MHz, a dc meter, and plenty of audio. With no limiting, no FM, everything you do to the front end shows immediately. This method also accommodates easily to a low cost signal generator, whose attenuation is never sufficient for a sensitive receiver.

Final Word on Gate No. 2 of the Mixer

Reworking the component values for the mixer, I again ran into oscillation when the dc bias was too high, this time showing up in the rf stage, even though there was no trouble there. So keep your eye on gate No. 2, it's a little touchy if you try to raise the mixer gain by too much bias. It does go up that way but being a form of regeneration, it

rapidly becomes unstable. A good stable second stage of rf is much better – and safer.



For maximum mixer sensitivity use plenty of L.O. power and gate No. 2 will operate fine without any dc bais. Just use a 47K resistor to ground.

Local Oscillator

This 45.3 MHz crystal oscillator and tripler to 136 is more or less standard, with the exception of the electronic switching of the different channel crystals. Building diode switching into the rig from the start allows you to put the switch anywhere you wish, one of such places being on a small panel under the dash of a car while the rig is out of sight back in the trunk or a similar concealed location. Some number of crystals should be decided on, such as 6 or 12, or leave enough space to install later as many as you decide to use. With this type of channel receiver no other type of tuning is available, so plan ahead.

Figure 4 shows the circuit, and if you haven't yet worked with electronic switching, don't let it worry you, it works. The switching diode is simply in series with the crystal; or rather, there is a diode in series with each crystal, and if no dc is applied to the diode to turn it on, the oscillator feedback path is cut off. When one of the diode resistors is grounded, making it conductive, current flows through the diode and, presto, you're on the air. Yes, there is some attenuation through a single diode, but inasmuch as L.O. power required is never very large, this is not troublesome if you provide for it. L.O. "tweaking" is provided by capacitor C1, which also is in series with the crystal. C2 also provides some frequency adjustment to the precise center of a given channel. Remember that between various rig and crystal manufacturers, quite a few cycles of variation can be expected – and indeed shows up – between what one considers to be, for example, "146.940 MHz" and the next. Presumably, a properly functioning counter can be used to correct this problem. However, I present the following two facts: Almost all rig makers install tweaking capacitors, and expensive ones at that, on both receivers and transmitters; secondly, two of the strongest repeaters I receive here on "146.940' heterodyne each other at something like 500 cycles. So put those tweakers in your rig, too.

You have only one conversion to think about in this receiver, but then you do have the sharp filter to consider. This is up to the maker, of course, and the first one I tested was well within the capability of the two tweaking capacitors mentioned above. The user (you) will probably think that for around $10 the manufacturer should be able to put it right on frequency, but if you have ever tried to make and sell something for "anybody" to use, you know there is

L1 = 3T. COPPER, NO. 14, 3/8"O.D., 1" LG., TAP AT 3/4 TURN FROM LOW END

L2 = 50 TURNS, NO. 34 DCC ON PHENOLIC FORM 1/8"O.D., 1/2 LG. WITH 6-32 IRON CORE TUNING SLUG OR SIMILAR. TUNE TO 10.7 MHz

L3 = 3 TURNS

Fig. 3. FET mixer stage.

another side to that story. At any rate, it works, and works well.

The tripler gives out with plenty of 136 MHz power, although you must get this into the second gate in proper fashion. After trying various types of cable connections, I found it better to go right into the gate from the top – or hot end – of the tripler coil. Of course, be very sure that the tripler *is* on 136 MHz by using a grid dipper or tuned diode to check this. Do *not* rely on a sensitive receiver. It is best to couple the tripler output into a diode receiver and meter, with audio to check on spurious, and test carefully for smooth tuning of both oscillator and tripler and also for switching and power. Do *not* allow marginal operation anywhere along the line such as "just on" or "just enough power" which will surely cause you trouble later on with a low battery, aging, etc.

The 10.7 MHz Filter

There is not much you can do to this one. It only has two terminals on it, one input and one output, and a ground connection and absolutely no tuning. It's well worth the price if you consider the alternatives of a lot of i-f coils plus tuning up.

The i-f, Detector, and af Preamp Block

The RCA CA 3089E FM i-f system is quite a device, for my money. The internal block diagram is shown in Fig. 5. This little ¾ x ¼ in. flat pack is of course the heart of this whole receiver. The moment I hooked it up and threw the switch, things happened, with no waiting around. Plenty of "interstation" noise, because I always leave the squelch until last, and tremendous sensitivity at the input. One inch or so of wire touched to the input and SW stations all over the world start piling in. With everything flat on a copper clad baseboard and/or in a metal box, it works fine for 3 dB points. This is for the i-f alone, without the front end. FM demodulation is by quadrature detection (of which more later). A logarithmic type meter output (S meter) is buffered, and the delayed agc for the rf is, also. AFC, which you may not use right away, is also brought out, and last but not least the squelch noise amplifier is included as well as the proper af input for the dc it produces.

The quadrature detector deserves and gets special mention here. When used in a BC FM set, its single tuned coil is shunted by a resistor and it is fed from the i-f by a choke coil in order to demodulate total deviations 150 kHz. To demoduate narrow-band FM, down to a total deviation of not more than 10 kHz, a high Q coil, no resistor, and a low value capacitor to the coil from the i-f must be used. The quadrature type detector used instead of a discriminator has seen long service in TV work. It functions, simply put, by virtue of its high Q which stays more or

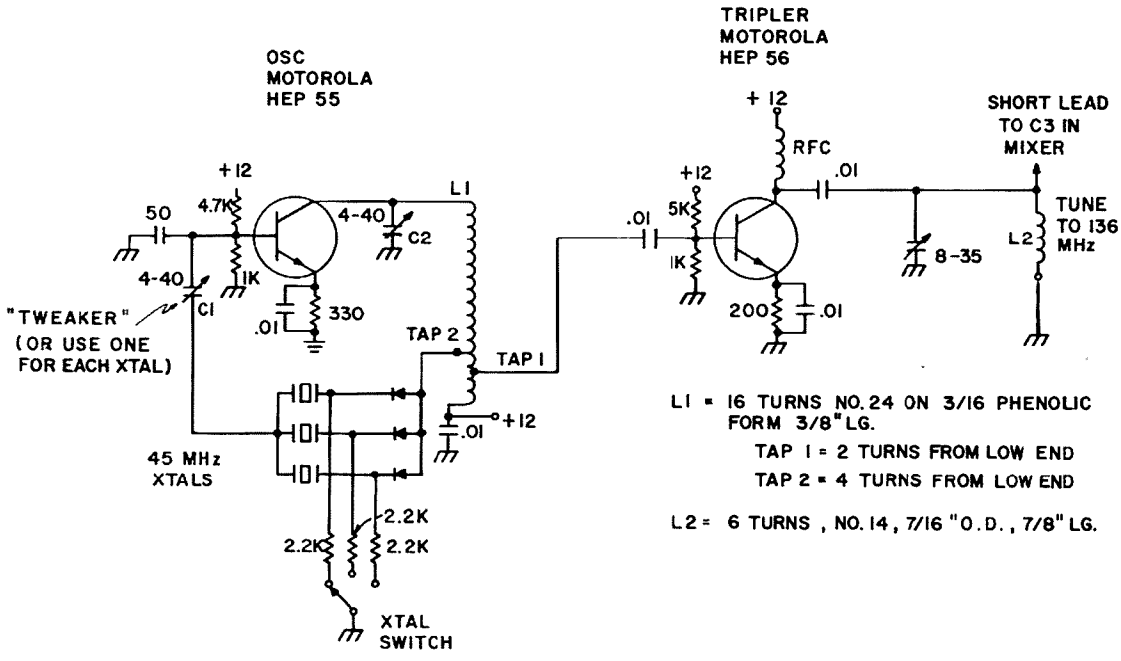


Fig. 4. Oscillator and tripler.

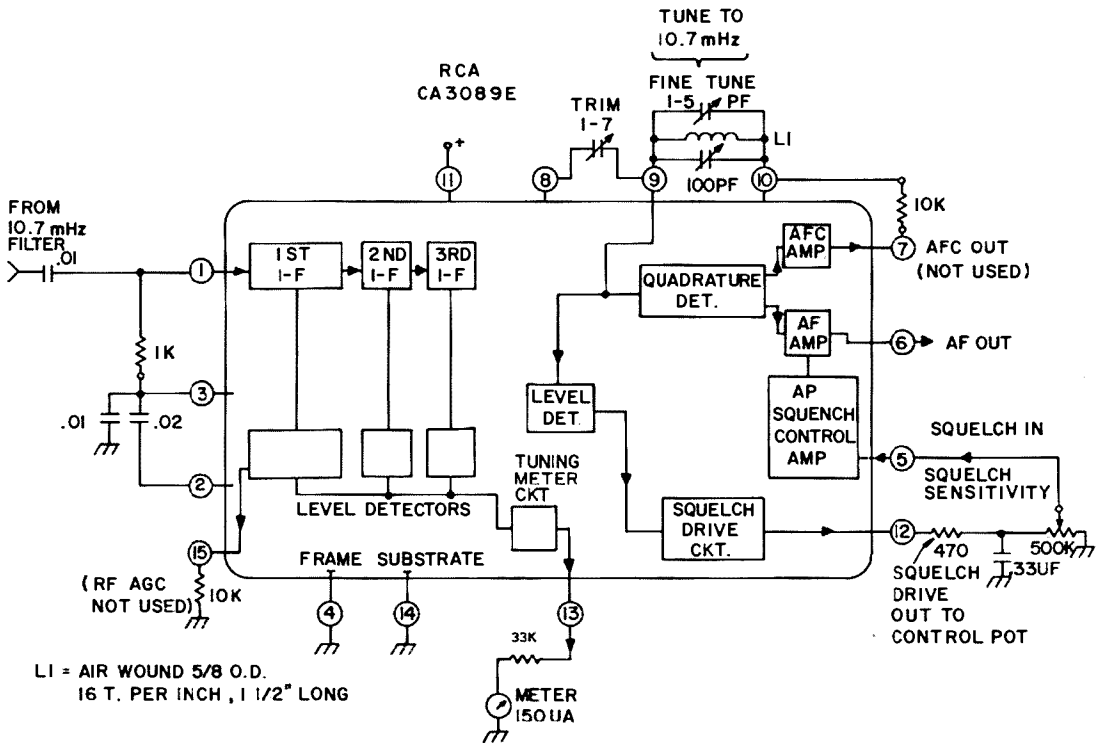

Fig. 5. I-f, audio, and squelch connections to CA3089E.

less on frequency – 10.7 MHz – while the incoming signal dances up and down with FM modulation above and below, unbalancing the detector which then produces nice, clean audio.

In order to do this correctly, the high Q coil must be tuned in exactly at the right spot, at 10.7 MHz, with a precision of a few hundred cycles at least. Actually, in practice, it isn't all that difficult. I just use a small fine tuning capacitor of 5 pF across the main 100 pF capacitor recommended for high Q, and on repeater voice modulation it is no more difficult than tuning a good receiver. And of course you then leave it that way. The series capacitor can be used to sharpen this tuning or broaden it, as you wish. Then it also is left alone. I'm just giving you some of the fine points of tuning up the quadrature detector, which is actually easier than tuning up a discriminator.

Just for fun, Fig. 5 shows you the various functional blocks in that miracle chip. Those "level detectors" shown are summed and sent to the tuning meter. This produces tuning indication even on strong signals, which are limited out at the detector. Detector "side-tuning noise" is greatly reduced by its careful application, all done internally for you by RCA to the squelch output, a nice feature. I recommend RCA Application Note ST-4698, "Advances in FM Receiver Design" for a more detailed description of everything that goes on in those 63 transistors in that little box. *(RCA/Solid State Division, Somerville, N.J. 08876)*

AF

This is the old story here, the tried and true one watt Amperex TAA-300. You can use your own favorite af if you have one. Five watts might be a little better in a noisy car. The Amperex is flat from 25 Hz to 25 kHz, leaving you plenty of room to trim response as you wish.

Results

I have logged so far 13 repeaters here, up to about a hundred miles, with a 38 in. piece of vertical aluminum, gamma matched to some 50 ft of ten-year-old 58/U cable.

This is a practical and working single conversion two meter amateur narrow-band FM receiver. It has been constructed and tested and circuit details furnished for the do-it-yourself crew.

P.C. boards are available from Bill Hoisington.

THE MOS-TONE ENCODER

This tone burst encoder for 2-meter FM repeater access is literally built around an MOS quad NOR gate (RCA CD4001/D or CD4001E), and boasts the following features:

- Miniature size – volume less than 0.5 cu. in.
- Very low current consumption – less than 3 mA with average operating conditions during tone generation
- Excellent temperature stability
- Simplicity – a dozen readily available components
- Versatility – can be easily adapted for multiple tone operation

The photographs tell the story about the compactness of this neat little gadget. W9ZDI's original unit is encapsulated in epoxy and mounted inside the case of his handi-talkie. Incidentally, if the MOS-Tone is used with a battery operated rig, or with any rig with a well regulated power supply, the voltage regulating components R1, C1, and Z1 can be omitted.

W9ZDI ran temperature stability tests on the tone generator, with very pleasing results. At room temperature the unit's output was trimmed to 2,250 Hz, which is the access tone for the local Milwaukee repeater, WB9ADX (146.34/76). The temperature was then lowered in a cold-chamber to -70°F (a little colder than it gets in a car that has been parked outside all day in Milwaukee in January), at which point the tone had increased a mere 7 cycles (0.3 of 1 percent!). When the unit ambient temperature had been elevated to 200°F the tone dropped but 18 cycles (0.8 of 1 percent). Hence we cautiously proclaim this unit suitable for mobile mike installation in most climates. If further information is desired on the temperature compensating features of this integrated circuit oscillator, as well as the derivation of the RC time-constant equation, see RCA Application Note ICAN-6267 (2/70).

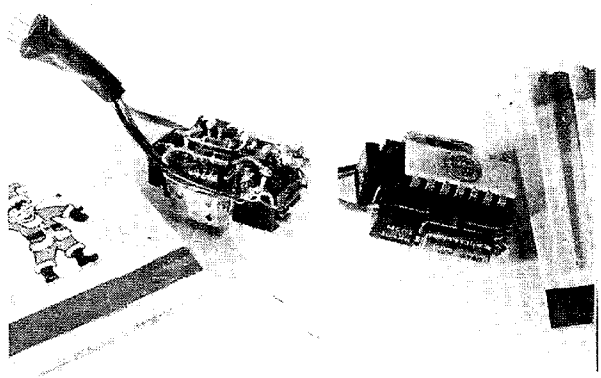

Fig. 1. MOS-Tone assembled by W9LCD measures 1" x 3/4" x 5/8".

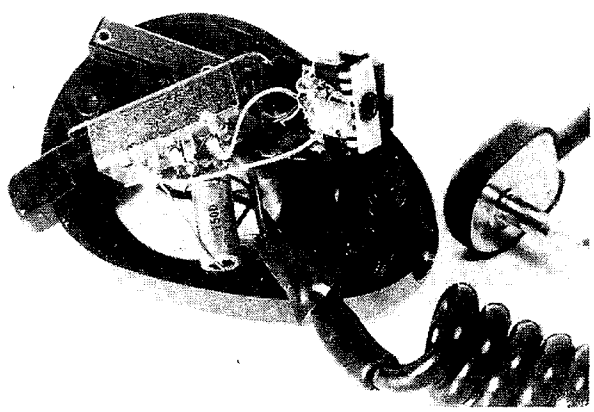

Fig. 2. MOS-Tone built into Regency HR-2 microphone by W9KQD. Long rectangular object in upper left is trim pot.

Theory of Operation

Referring to the schematic diagram of Figure 3, the first two NOR gates (pins 1-6) are connected as a multivibrator, the operating frequency of which is set by the time constant of R3-C2. Table 1 shows the approximate values of R3 for tones from 1,800-2,500 Hz, provided C2 is 820 pF. Fine frequency adjustment is accomplished by varying R2 (see Construction Notes). The third NOR gate (pins 11-13) is a buffer from which the output is taken. The output at pin 11 swings from 0 volts to the full B+ voltage; so R4, R5, and R6 attenuate the tone so that you can "talk over it." To decrease the tone still further, decrease R6 or increase R4. The final NOR gate (pins 8-10) is the timing circuit. The time constant of C4-R7 is about 0.5 second. As C4 charges, pin 9 goes "lo", which is inverted by the NOR gate to a "hi" at pin 10. This "hi" appearing at pin 6 shuts down the multivibrator. The buffer is deactivated in the same manner at pin 13, and prevents any possible chirp on the tone as it is cut off from reaching the output.

Construction Notes

All components are soldered directly to the pins of the dual in-line IC socket. Those that won't fit between the two rows of pins are left with slightly longer leads and are bent up around the sides, top, and bottom of the socket. The exact arrangement will depend upon the parts you come up with and your ingenuity. While the wiring is not critical, lead lengths should be kept as short as possible since stray capacitance will alter the tone frequency. One-eighth watt resistors are adequate. R3 and C2 should be high quality parts since their temperature coefficients govern stability. R3 should preferably be a thin-film, 1-percent precision type, and C2 a mylar or

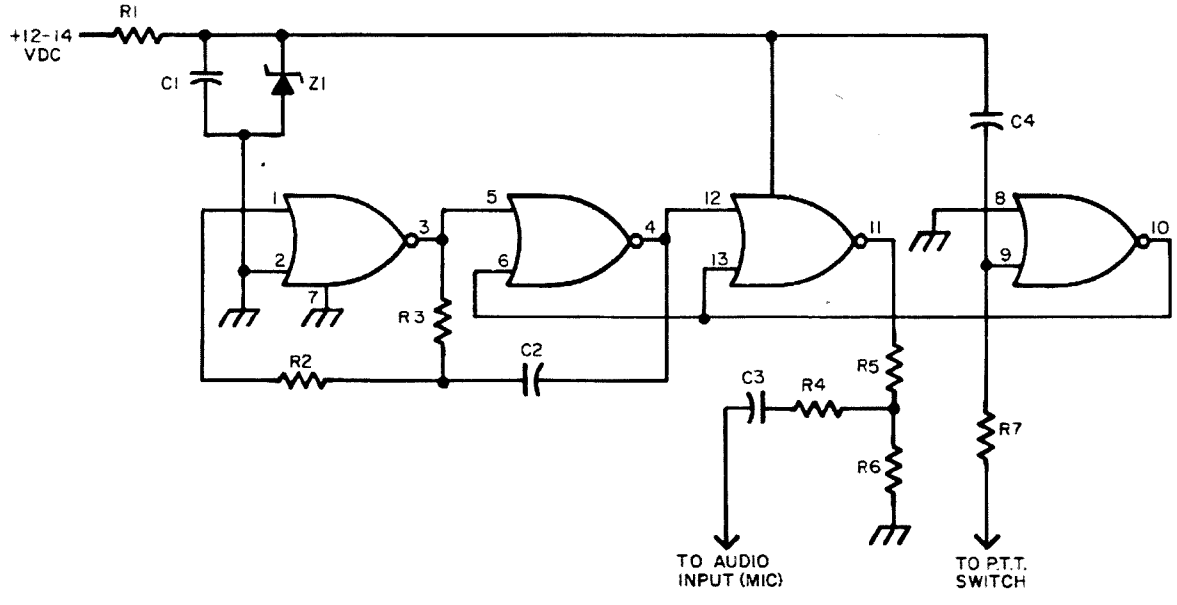

Fig. 3. Schematic of the MOS-Tone generator.

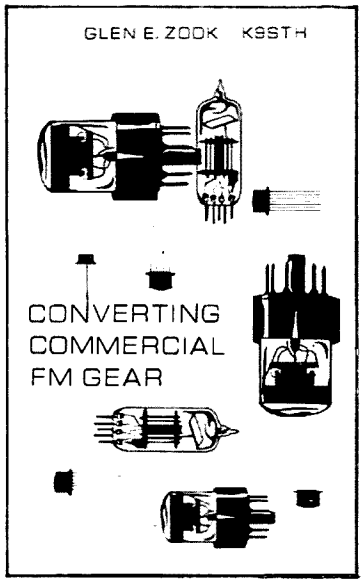
silver mica. The easiest way to fine adjust the tone frequency, if you have room for an additional component, is to connect a miniature trim pot, (100 k ohms or so) in series with R2 (see microphone photo). If it is desired to have the encoder adjustable to several different tones (for mobiling in areas where there are two or more repeaters), two schemes are available: (1) substitute a pot for R3 or (2) install a multiple-position rotary switch to select from several different small value resistors in series with R3. (These resistors could be 5 percent carbon types.) The switching arrangement shown is for use with rigs that use +12 volts to activate the push-to-talk relay, or the B+ line can be keyed. Still other arrangements are probably possible.

Conclusions

Several of these units have been built up by 2-meter FM ops in the Milwaukee area, and all are giving good service. If you wish an assembled and tested MOS-Tone, write W9ZD1 giving your frequency, tolerance, and size requirements.



Tone (Hz)	R3 (k-Ohms)	Tone (Hz)	R3 (k-Ohms)

A SHORT TONE BURST DECODER

For simple time control functions

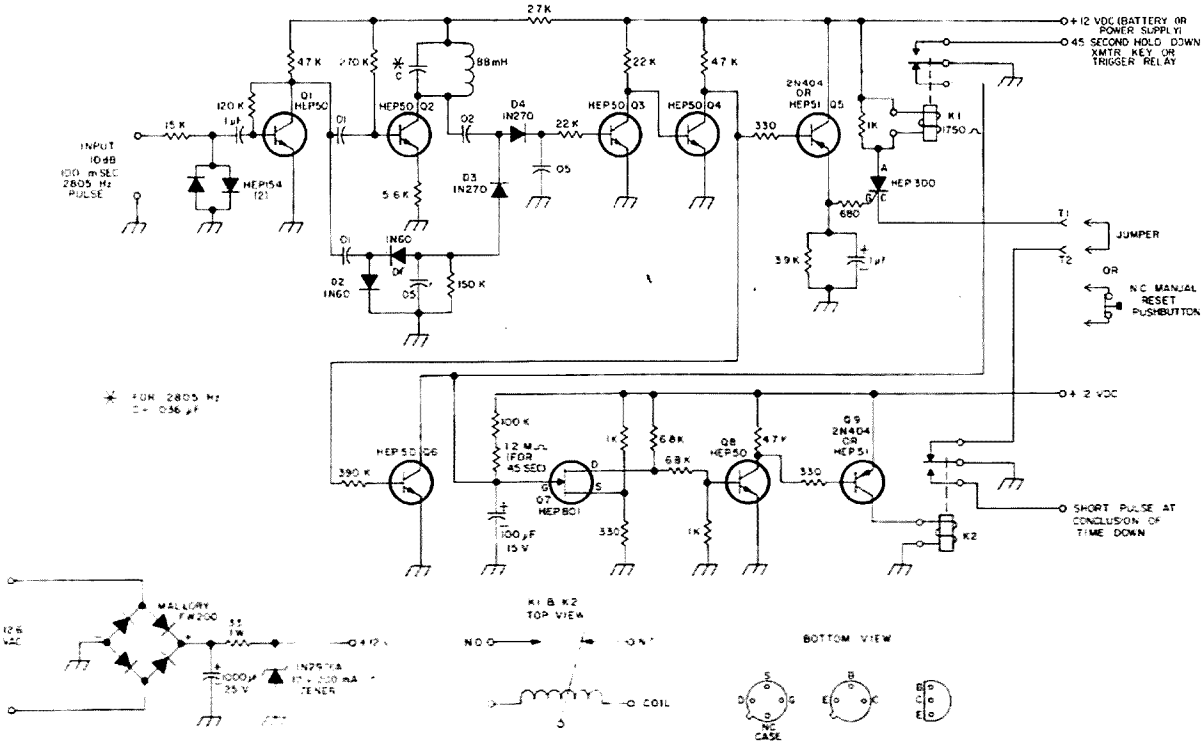
Certainly many articles on repeater control have appeared in the pages of 73 Magazine. Actually, more so than in any other journal both amateur or professional. One thing that you may find interesting, however, is that these unique applications do not necessarily have to apply to FM. All sorts of applications can be devised using small signal activated timers which are accurate, reset themselves, use somewhat standard voltages, and are able to withstand continuous service at very low power drains.

The following circuit was built for a paging application, but serves well in many other applications without modification. It could easily provide accurate control for FM repeaters – as well as something as simple as turning on your front door light with a toot from your (yours alone) auto horn . Other applications include: an automatic answer-back circuit for autostart RTTY, or by switching in a solenoid – snap an automatic picture from a SLOW SCAN MONITOR with the world's first SSTV autoscan.

The Circuit

The outstanding feature of this decoder is that it will respond to a 100 ms pulse of no greater amplitude than -10 dB. Anything greater or longer is a waste of time and energy. The keying bandwidth is less than 50 Hz and that's plenty of selectivity.

The tones activating the decoder, therefore should be relatively high in the band pass and in this case we chose 2805 Hz, because the lower frequency voice components of 100 ms duration could easily trigger the unit.



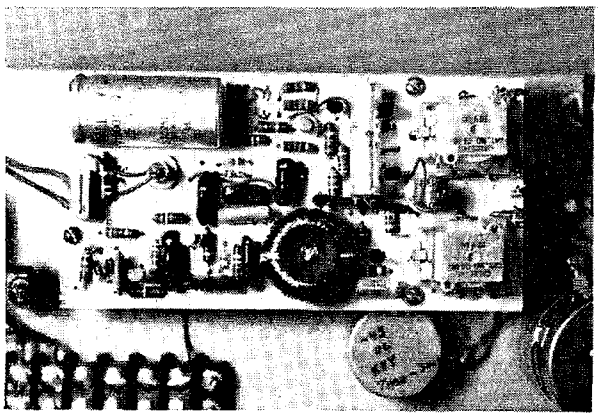


Fig. 1. Schematic of short tone burst decoder.

By sticking together some previous RTTY circuits (see Fig. 1), and using some of the suggested circuits in the current HEP Technical Tip Brochures (HMA-33), plus a few refinements, the following circuit does the job very well.

A signal of very low amplitude is unimatched to the base of Q1 (with clipping added if the level is not controlled). No matching problems were encountered and we have been successful in triggering everything from 3.5Ω to 20K with little or no signal loading or adverse effects in keying. Q1 amplifies the slightly clipped signal and drives Q2 and the 1N60 diode (negative) voltage doubler. Q2 amplifies the signal further and drives the collector LC circuit tuned to the desired triggering frequency. The combined amplified input and insertion loss of Q2 just about equals but is slightly greater than the output of the negative voltage doubler driven by Q1. The positive voltage doubler is connected in its parallel leg, not to ground, but by way of the filtered output of the negative supply. The combination keeps CR4 from supplying base/emitter current to Q3 until the positive voltage derived from the LC leg overrides all other audio on the channel. Q3 is made to conduct switching off Q4. This supplies an amplified pulse to Q5 and Q6. Q5 is normally off and when switched, supplies an inverted gate current to the Thyristor. In my original experimentation, the current draw required to hold the Thyristor into conduction was not enough so the relay K1 was loaded down by the 1K resistor. Although this was not the best thing to do, I later discovered that the very light load on the relay minimized the effects of heating or inductive spikes.

The relays are identical DPST imports made by the Calectro Corp. (DI-967, 12V, 5mW). They were selected because of price and size. The NC pole of the relay holds the timer gate of Q7 to ground until the Thyristor gate is keyed by Q5. The relay then supplies a ground to the NO contacts which can be used to key the transmitter or a slave relay of higher power. Ground to Q7 is released by this action and the 100 μF capacitor is allowed to charge through the 1.2 meg resistor. It takes 45 seconds for C1 to charge sufficiently to "pinch off" Q7,

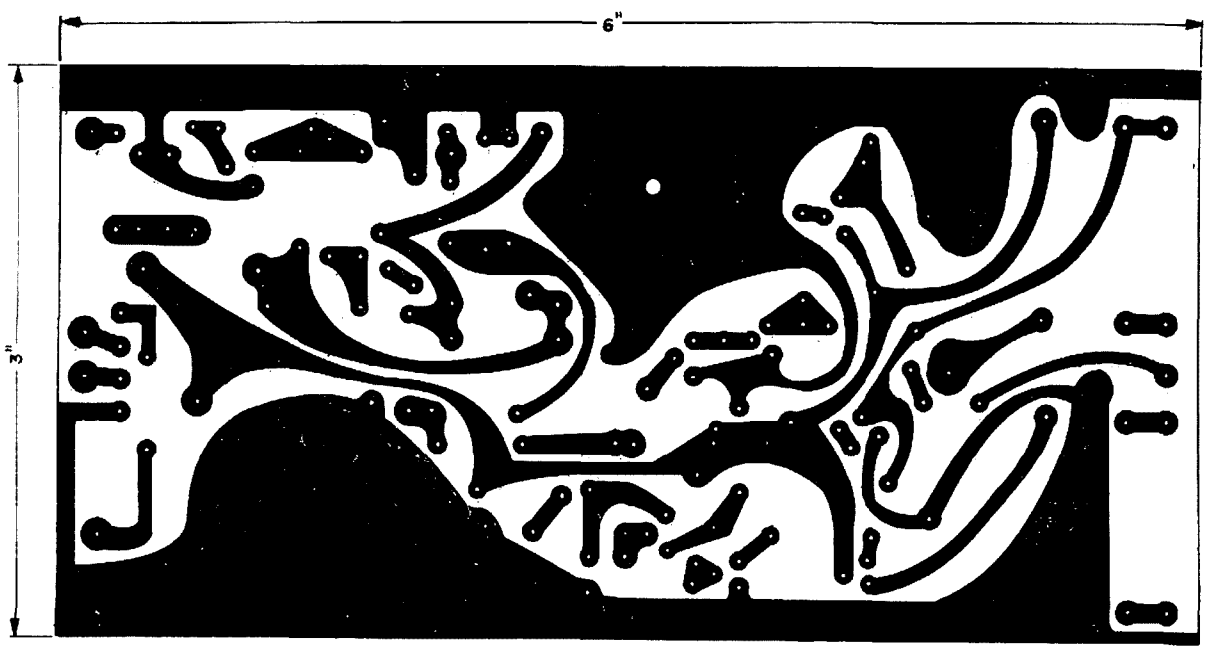

Fig. 2 Circuit board of decoder shown foil side up. (80% reduction)

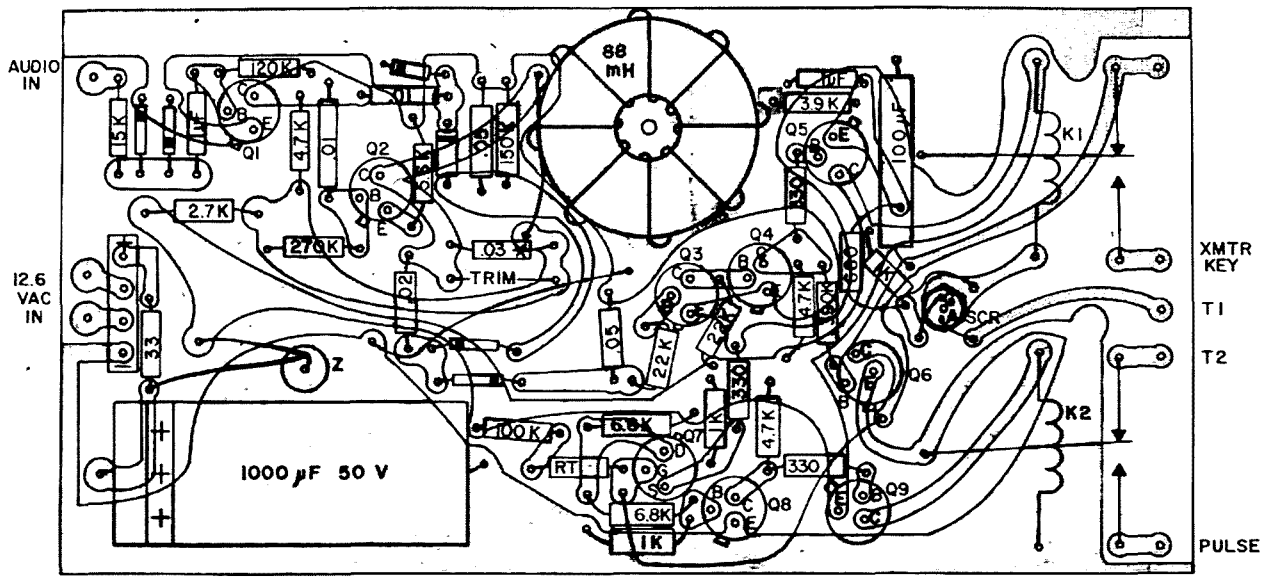

Fig. 3. Short tone burst decoder parts layout.

an N-Channel FET. With Q7 off, Q8 conducts causing normally conducting Q9 to cut off and release K2 momentarily. A short pulse to ground is one result which can operate the time out function, and at the same time the cathode of the Thyristor is momentarily broken with the other relay contact resetting the entire circuit.

Rt (at Q7)	TIME
1.2m	45 sec.
820K	30 sec.
390K	15 sec.

OR: use a 5M variable for 0–2 min.

Should a new pulse be received during the 45 second time down, Q6 switches on providing a fast discharge path to the timing capacitor without dropping out any relays. The general operation then is that the unit will remain on "until 45 seconds after the very last pulse is received." This is a convenient feature for repeater applications as the time of the tone burst can be very short and can be accomplished anytime during the time out period. As can be seen, there is also a degree of fail safe features which protect "stick-on."

Printed Circuit Board

After initial check out, I was concerned that no component would overheat or be in a "marginal state of operation." Long life and dependability were foremost. As can be seen from the photograph as well as the schematic, all components fit snugly on the board with only two over the top cheat wires used. My pc skills are still on the bottom of the learning curve. The board also includes a zener regulated power supply. Any great variation in supply voltage will of course affect the time period and this was considered a must under poor power regulation conditions experienced with repeater outposts. The total dissipation of the unit is 25 mA during standby and about 45 mA during time down.

This small dependable unit was used to control a wire-line controlled transmitter. It was a back-up system to dc control in the event the line would become shunted to ground (not necessarily interrupting audio) the "Phantom" control method might fall out. By preceding each control with a short tone burst, the circuit activates and is paralleled across a normal control relay. If the control relay fails to operate, the decoder takes over. If the relay does operate, the reset function "makes" and the decoder is made to reset at once.

There are all sorts of fancy applications possible with this unit and it is hoped that by making something a bit more simple to understand you will want to take a ham break and build something to amaze your neighbors with your resourcefulness.

A UNIVERSAL IF AMPLIFIER FOR A STANDARD OR PANORAMIC RECEIVER

The key considerations of good receivers are: high selectivity and image rejection; high overload – low cross modulation; and low noise factor.

If you built your own receiver, it also has to be rather easy to put it together and align it.

The described i-f amplifier uses two crystal filters in order to give 500 Hz and 5000 Hz bandwidth. It requires no alignment work, is uncritical to assemble and provides a high image rejection in standard receiver systems due to the operation at 9 MHz.

The gain is 46 dB and it can take.5 volts across the input terminals before cross modulation starts.

You can choose between the 500 or 5000 Hz bandwidth simply by actuating a dc switch.

Using the i-f amplifier in a standard receiver.

Although the intended prime application for this i-f unit is a panoramic receiver for two meters, you can build a standard receiver

The tuner and mixer and local oscillator units can be built in a standard manner. The i-f amplifier described follows the mixer stage, and no AGC is required because of the large signal handling capability. As usually done, AGC should be applied to the rf and also to the second part of the i-f amplifier. This second i-f amplifier does not require any selectivity and provides simply the additional gain needed to drive the detector. Any of the recent op amps or wideband amplifiers that meet the gain bandwidth characteristics may be used.

How to build a panoramic receiver.

This amplifier is ideally suited for VHF panoramic receivers. Figure 2 shows the detailed block diagram. The gain of the rf

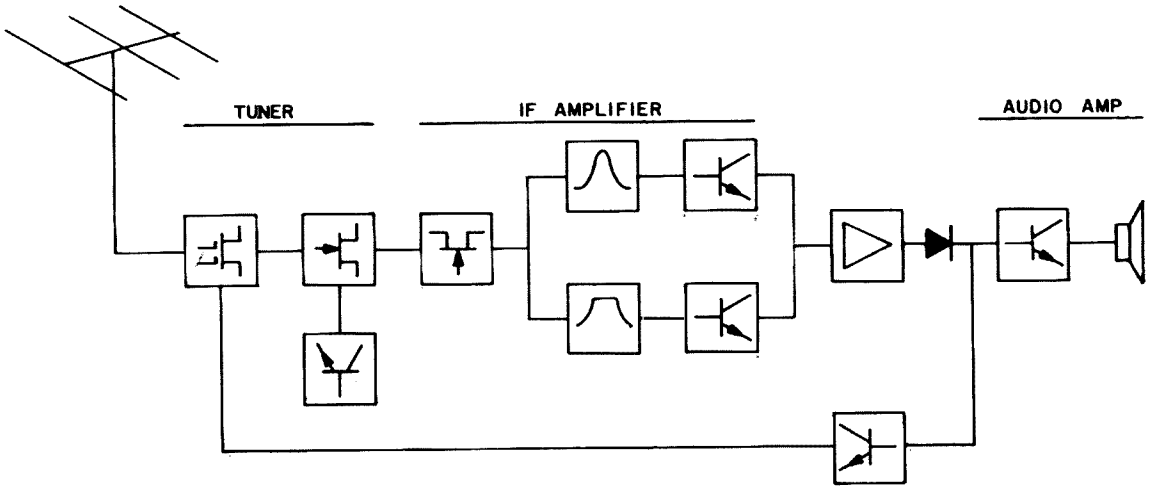

Fig. 1. Standard receiver block diagram.

amplifier and the mixer should be kept relatively low and not exceed some 15 dB in order to prevent overload of the following stages. In panoramic receivers AGC is not recommended, so al stages preceding the selectivity block must have extremely good signal-handling capability. The gain partitioning among the different functions of the receiver has to be made carefully.

The input signal passes the input attenuator which can be a passive and frequency-compensated resistive network. One can also use a dual gate MOSFET as rf amplifier and use several "preset" two voltage gates in order to provide fixed attenuation levels of say 0, -10, -20 and -30 dB.

The mixer should use FET for better cross modulation and low noise performance.

The local oscillator unit consists of the VFO, operating from 21–23 MHz, and an X-tal oscillator at 131 MHz. The oscillator mixer is followed by a band filter to provide the oscillator frequency of 153–155 MHz.

The attachment provides a simple sawtooth driver circuitry using unijunction tran-

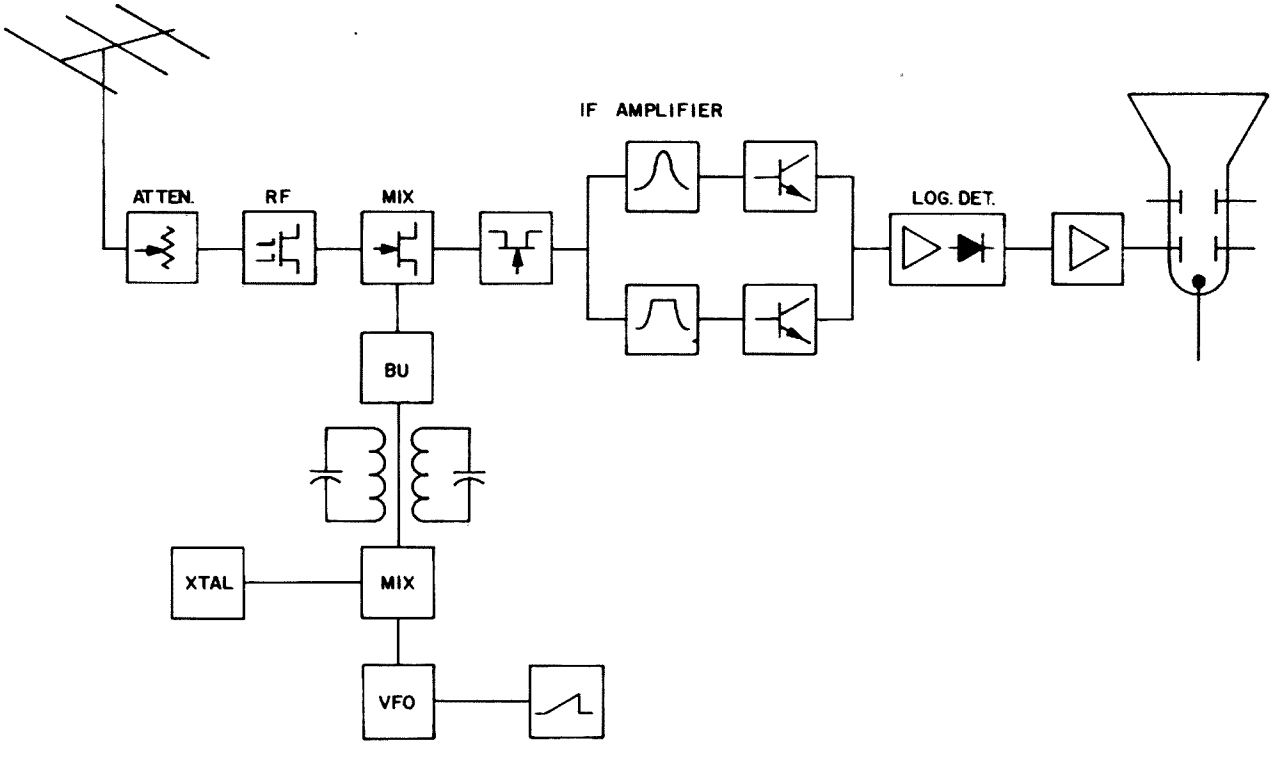

Fig. 2. Panoramic receiver block diagram.

sistor and FET, and the 21 MHz local oscillator using varicaps.

The i-f signal coming from the tuner is fed into the described i-f selectivity and gain block which is followed by a logarithmic amplifier. This logarithmic amplifier can be made by using operational amplifiers combined with diodes or transistors in the feedback path in order to simulate logarithmic characteristic. The dynamic range of this amplifier should be 50 to 60 dB

The two different bandwidths allow: a) scanning of the whole 2m band with a (sawtooth) sweep frequency of 15 Hz which is, depending on the used display tube, just above the level where the flicker effect becomes negligible (the bandwidth in this case is 5 kHz); and b) scanning a section of the whole 2m band and obtaining a high resolution. The bandwidth for this is 500 Hz. This small bandwidth allows an accurate analysis of the signal for instance to determine the modulation depth, the bandwidth, the sideband symmetry, etc.

The i-f amplifier unit.

The complete amplifier is shown in Fig. 3. It consists of a periodic FET preamplifier, the solid state bandwidth switch section, the two crystal filters, and the post amplifier which provides most of the total gain of the whole amplifier. The purpose of putting an FET as amplifier ahead of the filter and the switch is to achieve a high signal/noise ratio and to overcome the losses of the filter and the switching arrangement. Also the FET can withstand high signal levels without causing distortion, especially if the device is operated in common gate mode.

Generally filter losses are in the order of 1 to 4 dB depending on the selectivity and frequency of operation and any losses ahead of an amplifier add directly to the system noise figure.

Other advantages of a common gate mode FET are: a) low input impedance – no tuned circuit is required. In most cases tuner and i-f amplifier are separate "building blocks" which are physically separated. They normally are interconnected by a low

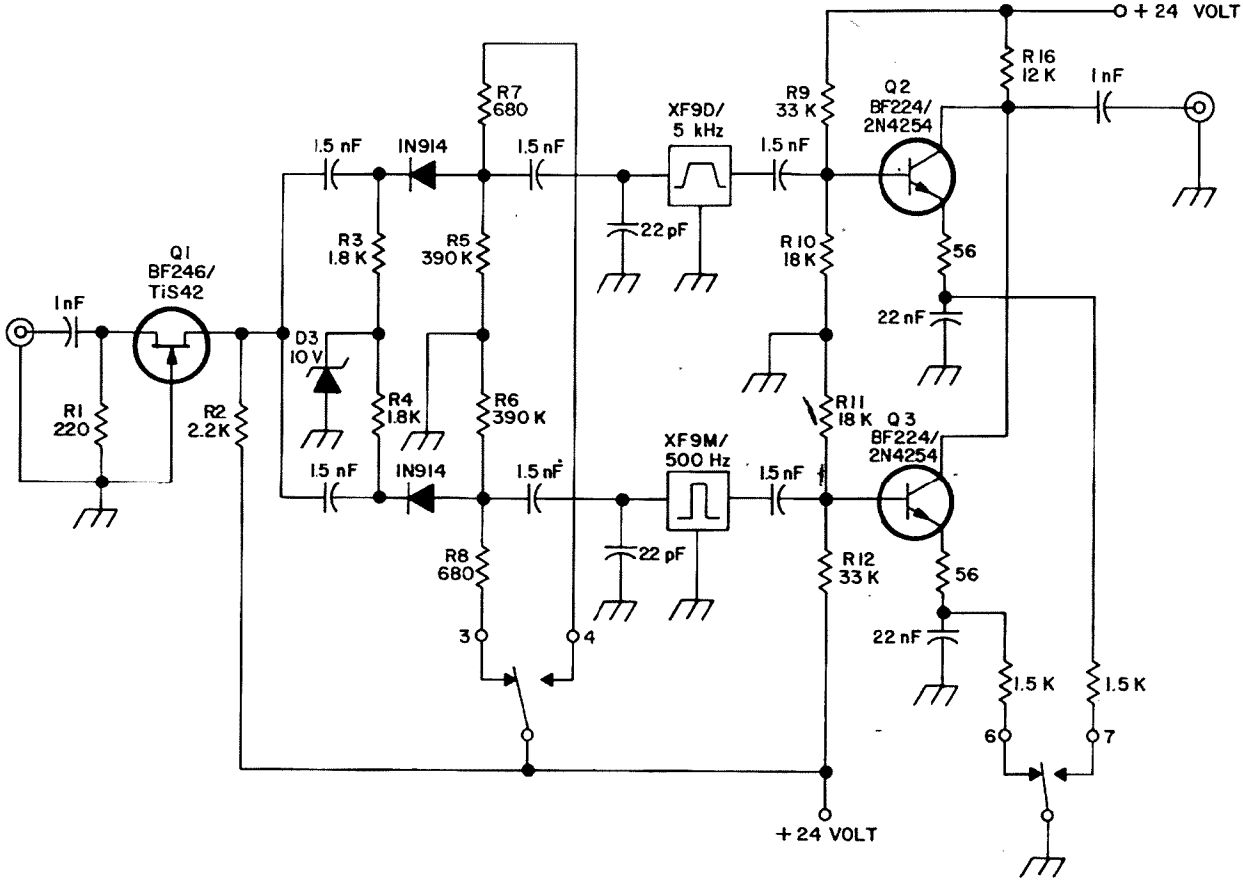

Fig. 3. i-f amplifier circuit diagram. Note that a few capacitance values are given in nF. 1 nF = 1000 pF = .001 μF.

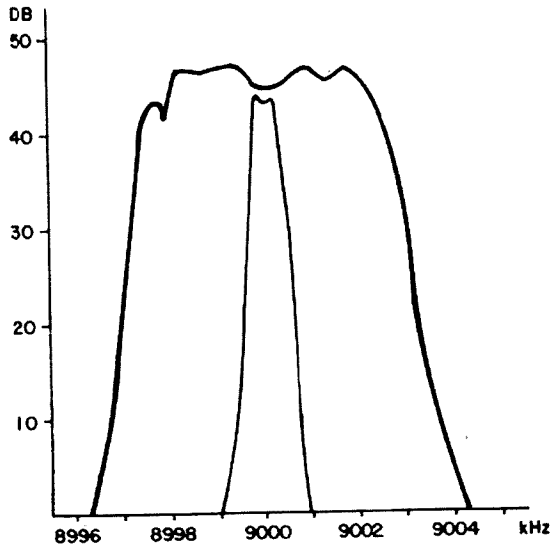

Fig. 4. Amplifier filter response curves.

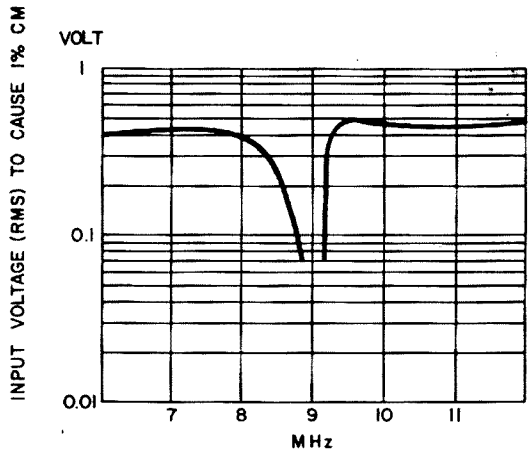

Fig. 6. Cross-modulation performance curve.

impedance coaxial cable. b) The stability of an FET in common gate is excellent. and c) The biasing is extremely simple, the gate of Q1 is tied directly to ground and only R1 of 220Ω is needed to set the drain current at approximately 8 mA.

The voltage gain is Vu = Yf x RL where RL is the equivalent parallel resistance of R2, R7 and R3 respectively, R2, R4 and R8.

The selectivity and bandwidth is switched from 500 Hz to 5000 Hz by the two switching diodes D1 and D2. If D1 is switched on, by applying a positive supply voltage to the terminal 4, D2 is automatically reverse biased by -10 volts due to the zener diode, D3, and the biasing resistors R4 and R6.

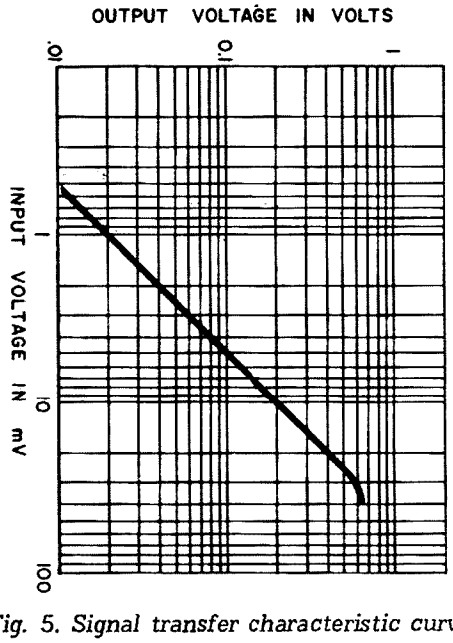

Fig. 5. Signal transfer characteristic curve.

The passband characteristic is very sensitive to the matching conditions and both filters are matched at the input and output terminals to see 500Ω and a parallel input capacitance of 30 pF.

The actual filter response is shown in Fig. 4. The two curves were taken across the input and output of the amplifier unit. The flatness is only 1 dB for the 500 Hz and 3 dB for the 5000 Hz filter.

Q2 and Q3 are individual amplifier stages for the two filters. Using individual amplifiers adds significantly to the channel separation. D1 and D2 are switched on for the 5000 Hz channel, while D3 and Q3 are in the off stage and vice versa for the 500 Hz channel.

The voltage gain is 46 dB and the output swing is linear up to 5.5 volts RMS. This corresponds to an input level of 27 mV. The transfer characteristic of the amplifier is given in Fig. 5 while the cross modulation performance can be seen in Fig. 6. The measurement condition for this test were set as follows: the desired signal is 1 mV across the 50Ω input terminal. The undesired signal was 100% modulated. The undesired signal to produce 1% cross modulation is plotted as a function of the frequency deviation. The graph shows that cross modulation only occurs at input level of 400 to 500 mV RMS. If one uses a 16 db tuner, the input level can be as high as 83 mV at the antenna terminals.

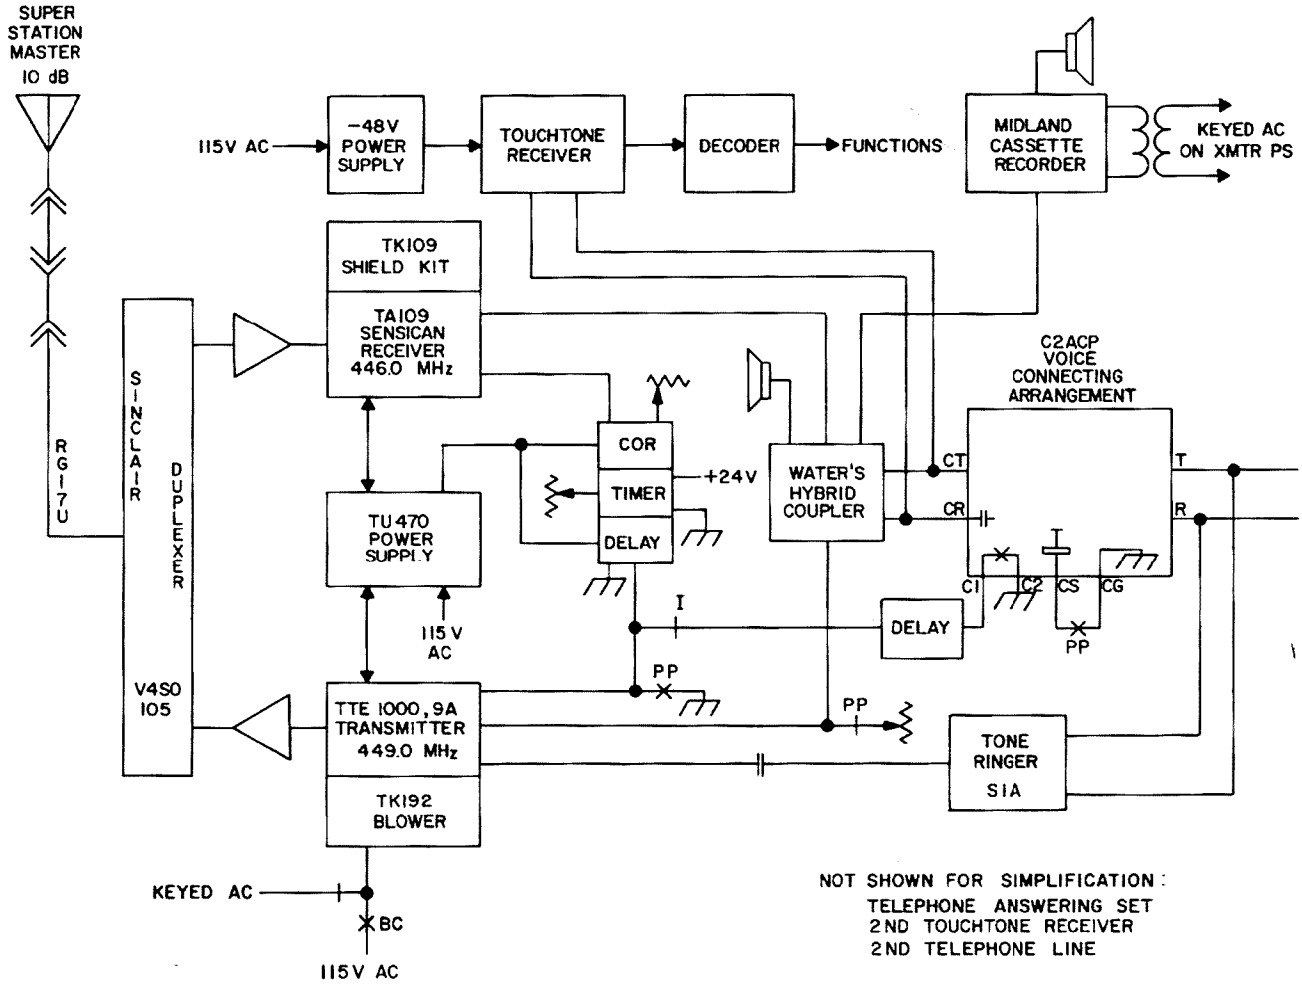
TOUCHTONE AND TELEPHONE CONNECTING ARRANGEMENTS

Until recently, auto-patch connections to the telephone lines have been on the shady side. Most hams prefer touchtone. Bell Telephone has approved tariffs for the use of customer-provided tone address signaling (touchtone dialing). Bell's "automatic voice coupling arrangement" type C2ACP must be used. It is available for $10 installation and $3 per month.

This coupler is a two-way device providing the customer with a contact closure when ringing is received, with a control lead to seize or operate the coupler, with limiting and isolation to protect the telephone network, and with dialing connections if touchtone is not available. It is worth the effort and price to have a legal patch that can be shown to anyone.

Figure 1 shows it connected to WA3IGS repeater/auto-patch. All leads are designed on the diagram.

Bell Telephone will provide you with a Technical Reference #PUB42207 when you order the coupler, if you request it. It gives full details of operation and interconnections.



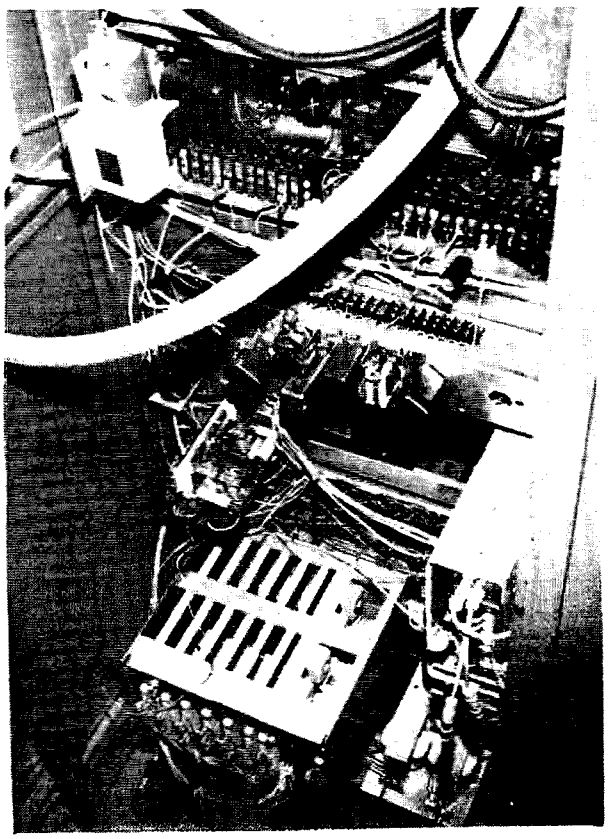


Fig. 1. Block diagram of the WA3IGS auto-patch repeater.

Touchtone dial mounted on the front of a HT series handie-talkie.

Rear view of the WA3IGS repeater showing the A3 Touchtone decoder.

Pads

Touchtone pads for the auto-patch are readily available from many suppliers, including Greybar in Philadelphia and Stromberg Carlson in Rochester, New York. The 35A3A type dial (ITT #3200G450) is available from Greybar for about $21. The Trimline miniature dial type 82A2A is available from Stromberg Carlson for about $24. These are identical to Western Electric types. Both are the 12-button version.

The picture shows the Trimline dial mounted in a minibox and attached to a Motorola H24DCN HT. This makes a neat portable telephone that even AT&T envies. The 11 and 12 buttons are used to enable and disable the patch. If you are afraid to drill the HT cover, you can order another from Spectronics at a very reasonable cost and drill it up. The Trimline is not limited for use to the HT series. It will work just as well with any other FM rig. Figure 2 shows the Trimline schematic and its connections.

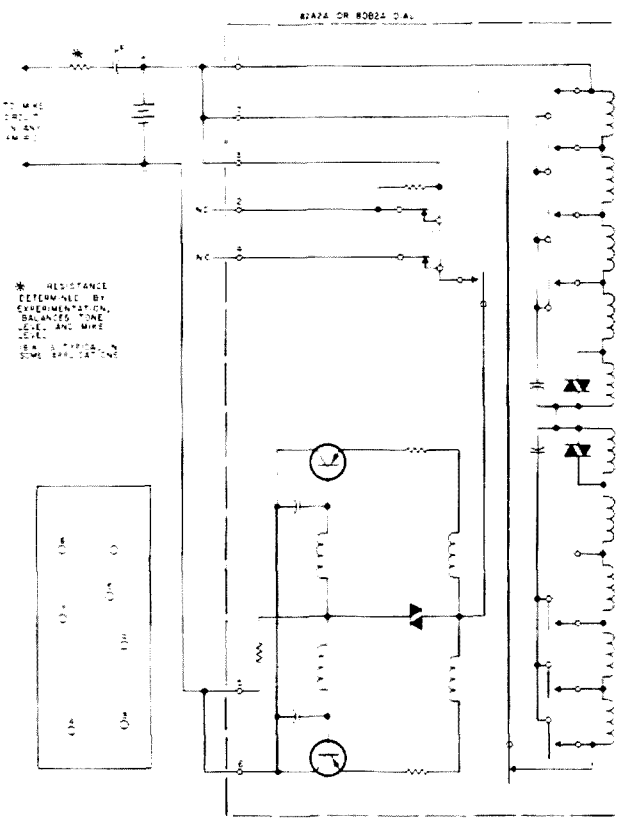

Fig. 2. Trimline schematic and its connections to an FM rig.

Decoders

Touchtone receivers are needed in a

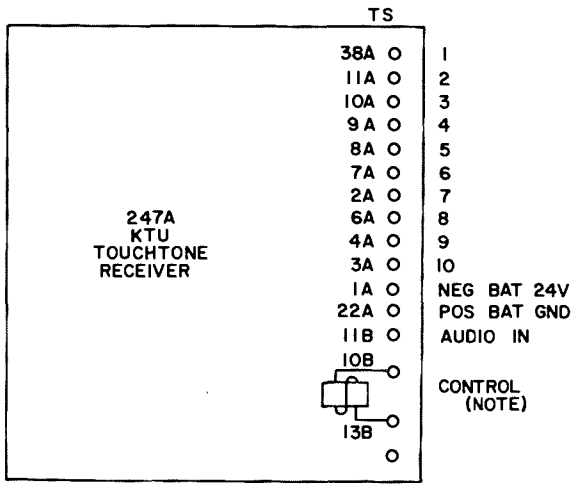

Fig. 3a. Connections for the 247A Touchtone receiver.

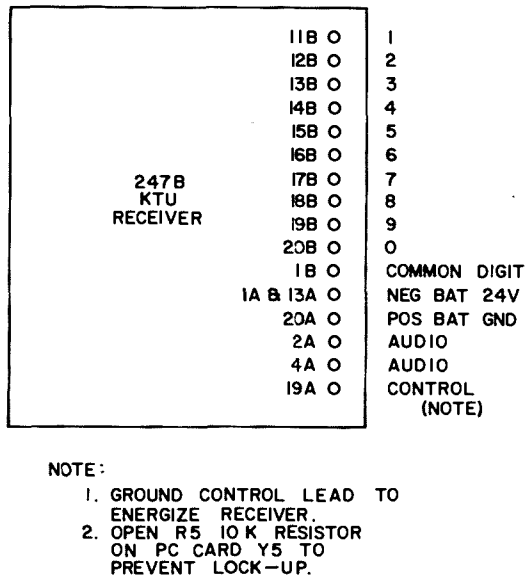

Fig. 3b. Connections for the 247B Touchtone receiver.

touchtone auto-patch system to enable or disable the system. Basically, they are nothing more than 7 or 8 tone receivers (L-C circuit preceding an amplifier) with logic connected to the output. Although they are relatively easy to build, most hams prefer to scrounge one of many types available.

One source is Digitone in Ohio. They also offer many other items useful for auto-patches. Other sources included Stromberg Carlson and various surplus houses. Western Electric no longer sells outside the Bell system.

Many types of decoders are available. The 247A and 247B types are used primarily on customer intercom systems. The A3 is a standard Central Office decode. Hundreds of A3 types are either floating around or

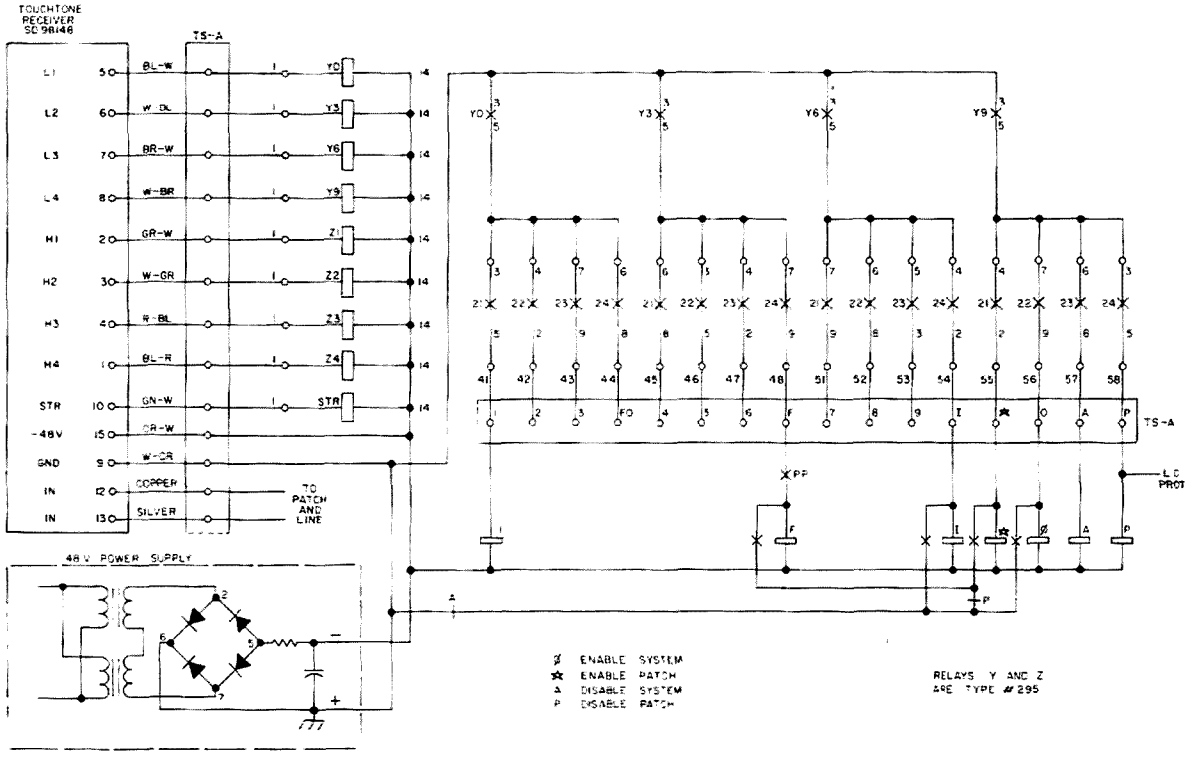

Fig. 4. Connections for the SD98148 receiver.

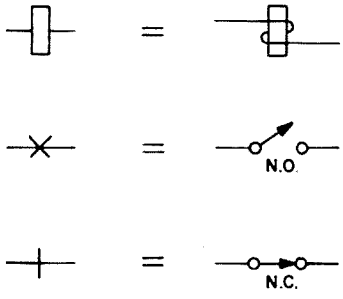

Fig. 5. Legend for the connection diagrams.

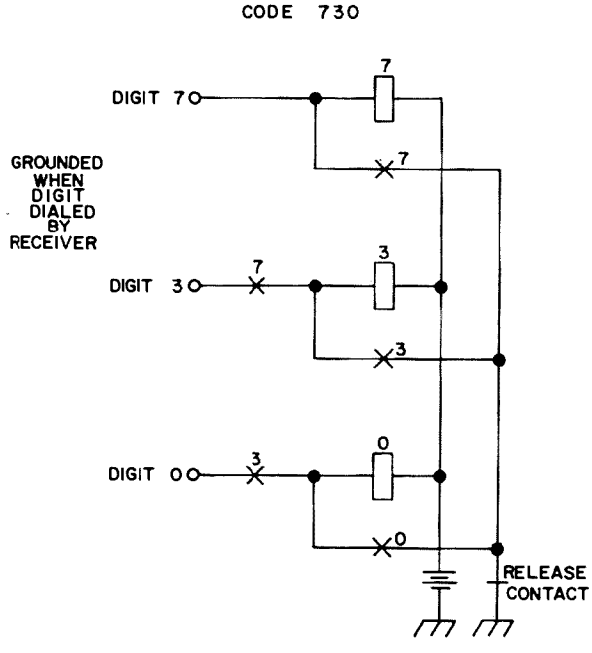
smashed as a result of changing the military Autovon Network from 4 wire #5 crossbar to electronic switching. These were 16-button decoders which had one additional tone (4 digits). Out of 73 decoders from a Philadelphia military exchange, only 16 could be saved from the sledgehammer. AT&T felt that this was enough, since previously released equipment showed up in commercial service again in another area. That's what happens! Others were released in other areas, so keep your eyes open. Please don't ask for any from this area. They are all in use.



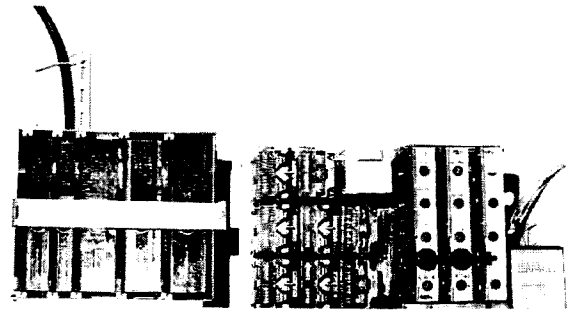


Fig. 6. Simple circuit for converting digits to functions.

The 247A and 247B Touchtone decoders.

The photo shows the 247 A & B types. Figures 3, 4 and 5 show hook-up connections to get them operating. Figure 6 shows a simple circuit for converting digits to functions. There is no limit to building out the codes.

Protection

Protection for auto-patch long distance calls is simple. The Bell system has in most areas the prefixing of digit 1 for toll calls. A gate that detects dial tone (350 and 440 cycles) and the digit 1 at the same time simply disconnects the patch. See Fig. 7 for an example. In the event you want protection and you don't have dial 1 prefix, you can actually decode entire telephone numbers or the first 3 digits and kill the call if the number dialed is other than what's in the program. Your tape recorder log is your best insurance policy.

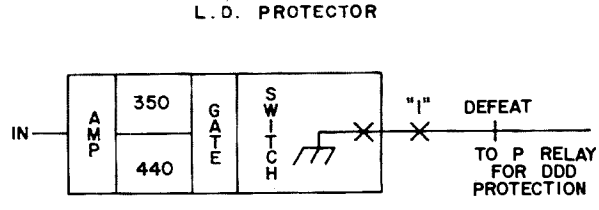

Fig. 7. Protection circuit to guard against toll calls.

Conclusion

Since no two auto-patch systems are the same, I have generalized in some areas. Every one has his own way. Anyone desiring schematics of WA3IGS may have them upon supplying a self-addressed, stamped envelope and cost of reproduction. It took three of us to get this system working properly over a three-year period. I recommend this type of system only to skilled organizations and not as an individual's private system.

THE SIMPLEST AUDIO IC YET!

Audio Output IC's have been coming out thick and fast. Practically every IC manufacturer has one in his catalog. However, my choice for simplicity, performance, and lowest parts count is National Semiconductor Corporation's LM380N.

Just look over Fig. 1. Would you believe just six parts plus heatsink and battery? And it's a dandy! It is rated for 2 watts output at 18 volts. Mine has put out over 2½ watts with 18 volts, and just over one watt at 13 volts. Since it can take 22 volts without damage, yet still work at 8 volts, it is perfect for mobile use without any worries about either weak or overcharged car batteries. The output looks very clean on a scope and the manufacturer rates the typical total harmonic distortion at only 0.2%. Quiescent supply current is only 7 mA at 18 volts and bandwidth extends to 65 kHz. (It was really designed for a simple, high quality record player system. Two LM380N's, a ceramic stereo cartridge, two speakers, and the result, easy stereo!

In connecting it up, pin 7 is the official negative connection for the power supply. However, since it needs about six square inches of copper clad board for a heatsink, I soldered pin 7 along with heatsink pins 3, 4, 5, 10, 11, and 12 right to the foil side of a copper clad printed circuit board 2" x 3" square. The rest of the components were soldered to insulated terminals bolted to the board. The 5 μF capacitor from pin 1 to ground reduces ripple, but the circuit works even without it!

The price for the LM380N is only $2.25 each when you buy one at a time; really a bargain!

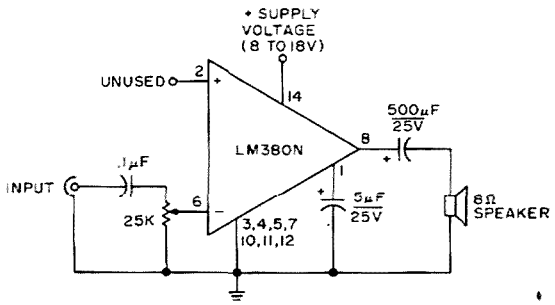

Fig. 1. The simplest audio IC yet.

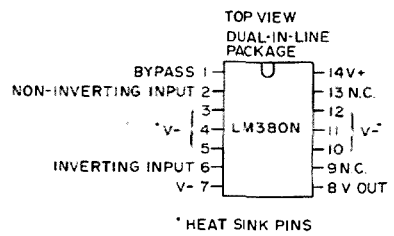

Fig. 2. Top view, dual-in-line package.

Figure 2 shows the pin connections viewed from the top of the IC. You can bend the heatsink pins to lay flat on the board before soldering and bend the others up, away from the board for connection to the rest of the circuit. If you solder to the IC quickly with a hot iron, no damage will result as the lead temperature is rated at 300°C for 10 seconds during soldering.

You can bet that my unit is going to be the beginning of a tiny SSB receiver for portable and mobile operation.

TUNING TIPS FOR USING VOLTAGE VARIABLE CAPACITORS

The use of inexpensive varactor diodes to provide linear and versatile tuning schemes for homebrew oscillator projects is described in detail. The information is applicable to circuits for HF transceivers as well as those for VHF equipment.

Voltage variable capacitors or varactors have been available, basically, since transistors were used. The base-collector junction of many transistors (one example is the 2N3565), as shown in Fig. 1, can be used to form a voltage variable capacitor usable over a range of 10–15 pF.

The effect of having a diode junction, either as part of a transistor or as a separate diode, forming a capacitance which varied as the voltage impressed across the junction, was supposedly discovered by accident rather than by any scientific research aimed in that direction. At any rate, varactor diodes specifically meant for use as voltage variable capacitors are now available in a large range of capacitance values from many manufacturers at very reasonable prices. It is rather surprising, therefore, that so few amateur equipment designs employ these diodes and rather stick to old-fashioned air variable capacitors. Hopefully, the material presented in this article may assist various

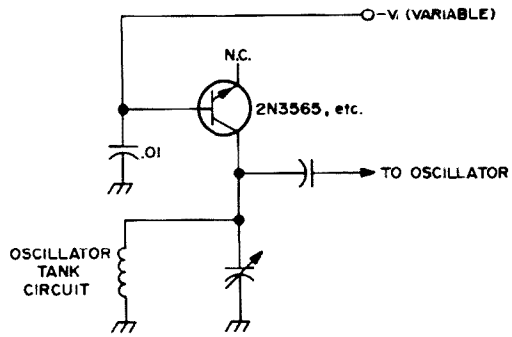

Fig. 1. Transistor diode junctions can serve as varactor diodes. Several receivers/transceivers have used such schemes for incremental tuning.

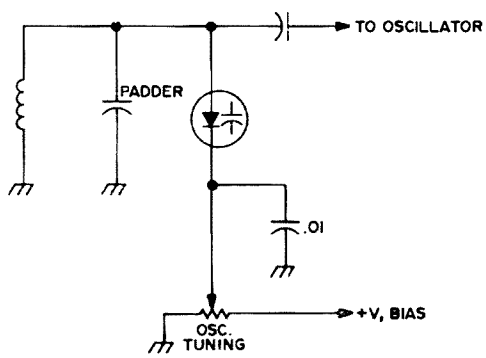

Fig. 2. Basic use of tuning diode. One side of diode is dc grounded through the oscillator tank coil.

Proved in Commercial 2-way Now Available To Amateurs!

Larsen Mobile Gain Antenna 144-148 MHz

The result of over 25 years of two-way radio experience. Gives you . . .

- **3 db + gain over 1/4 wave whip**
- **6 db + gain for complete system communications**
- **V.S.W.R. less than 1.3 to 1**
- **Low, low silhouette for better appearance**

The fastest growing antenna in the commercial 2-way field is now available to Amateurs. It's the antenna that lets you HEAR THE DIFFERENCE. Easily and quickly adjusted to any frequency. Hi-impact epoxy base construction for rugged long life. Silver plated whip radiates better. Handles full 100 watts continuous. Models to fit any standard mount. Available as antenna only or complete with all hardware and coax.

Get the full facts on this amazing antenna that brings signals up out of the noise . . . provides better fringe area talk power. Write today for fact sheet and prices.

Sold with a full money back guarantee. You hear better or it costs nothing!

also available . . .
5 db Gain Antenna for
420-440 MHz and 440-460 MHz

readers to more easily utilize these very useful diodes.

Particularly for the tuning of oscillator circuits, varactor diodes when combined with the proper type of potentiometer control offer tuning possibilities and variations which would be impossible, or at least extremely difficult and costly to achieve, using conventional air variable capacitors and mechanical tuning systems. A number of examples are presented later which illustrate the various tuning possibilities possible with varactors. A good basic understanding of what varactor diodes can do and what their specifications mean is, however, basic to successfully using these diodes.

Basic Operation

Varactor diodes as voltage variable diodes function basically on the idea that when a diode junction is reverse biased with an increasing voltage potential, its depletion region increases and its capacitance value decreases. The increasing potential can be viewed as pulling the plates of a capacitor further apart and thus decreasing its capacitance. The usage of such a diode in a simple fashion as the tuning capacitor for an oscillator is shown in Fig. 2. The diode is tuned by the potentiometer which, since it controls only the dc voltage impressed across the diode, may be located at any distance from the diode. The dc ground return for the other side of the diode is made through the grounded end of the oscillator coil. The whole scheme would be almost ideally simple if it were not for the fact that the diode's quality as a capacitor (Q) depends upon the frequency of operation and the diode's capacitance variation is not directly related to the rotation of the potentiometer arm.

Practical Diodes

The varactor diode usually does not exhibit a linear capacitance variation with applied voltage, although there are some variations to the general rule. Usually a diode exhibits a capacitance variation which varies as some exponential relationship with the applied bias voltage. Diodes are usually classified by their nominal capacitance value at some reference bias voltage. For instance,

the graph of Fig. 3 shows a "47 pF" diode, the capacitance value which it has at a reference bias voltage of −4V. The capacitance range of the diode, a 1N3628, is actually from 25–125 pF. The capacitance variation is shown by the graph and is characteristic of diodes produced by many manufacturers. Unfortunately, the capacitance variation is not linear or logarithmic with the applied bias voltage and no potentiometer taper is available which will directly provide a linear capacitance variation with linear rotation of the potentiometer shaft. A number of ways can be employed, however, to correct this situation as described shortly.

Figure 4 shows the capacitance versus bias voltage curves for two diodes which have a capacitance range that many amateurs would find useful in building oscillators for the HF frequencies. The 1N3627 is classified as a 22 pF diode (at 4V bias). Its useful capacitance range is from 12 pF (at 20V bias) to 50 pF (at .1V bias). The BB103 is a European type made by Siemens and available here. Its capacitance is quoted as 29 pF (at −3½V bias) and its effective capacitance range is from 13–52.5 pF. The two curves are shown to illustrate how the characteristic curves of two diodes from different manufacturers can vary slightly. If one wanted to build an oscillator, for instance, with a very linear readout it is a good idea to obtain the characteristic curve of the diode family from a manufacturer.

Just to illustrate the interesting types of varactor diodes which are available for tuning purposes, Fig. 5 shows an unusual dual diode made by Siemens, the BB107. The diode costs around $5 and is designed primarily for use in AM receivers. The diodes have a common anode connection and the capacitance of diode section D1, for the same bias voltage, always has a capacitance a fixed amount different than that of the other section D2. The graph illustrates this variation. Such a diode could have some very interesting application for oscillator tuning. Operated over a smaller capacitance range than the total available, the diode exhibits an almost perfectly linear capacitance variation with bias voltage. By switching from one diode section to the other in a properly set up oscillator circuit, one can switch back and forth between the CW and phone portions of a band. For a LF converter, the diode can be used exactly as it was intended – one diode section controlling the tunable oscillator and the other the input tuning to a mixer stage.

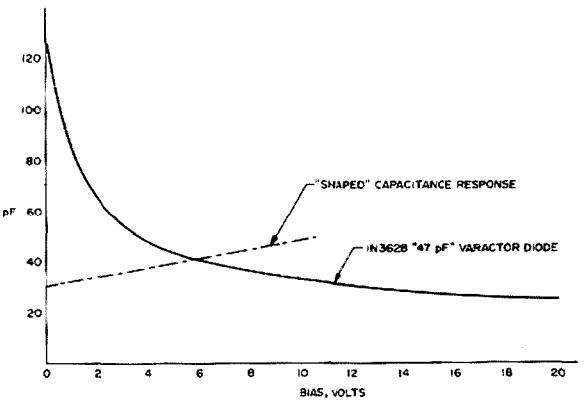

Fig. 3. Response of a typical "47 pF" tuning diode (solid line).

As with many electronic components these days which are a bit advanced, the question of availability often becomes a problem when one finally decides to build a piece of equipment. Unfortunately, only a very few varactors designed for voltage tuning usage as capacitors have standard 1N numbers. Most cannot because the capacitance/bias voltage relationship varies from manufacturer to manufacturer and the assignment of 1N numbers implying interchangability would not make sense.

One "family" of varactor diodes that should have special appeal to amateurs is the Motorola MV2000 series. The available types are shown in Table 1. They are available from any large distributor of Motorola semiconductors (Allied Radio, for instance) at only 90¢ each. The diodes will have a capacitance curve similar to that shown in

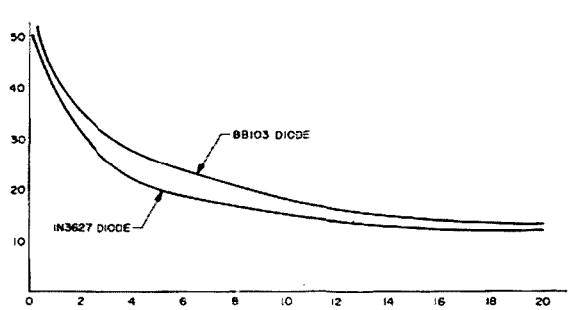

Fig. 4. Response curves of two typical 22–29 pF labeled diodes.

Table I

Type	4V Capacity	Q (50 MHz)	Tuning Ratio (2–30V)
MV2101	6.8	450	2.7
MV2102	8.2	450	2.8
MV2103	10	400	2.9
MV2104	12	400	2.9
MV2105	15	400	2.9
MV2106	18	350	2.9
MV2107	22	350	2.9
MV2108	27	300	3.0
MV2109	33	200	3.0
MV2110	39	150	3.0
MV2111	47	150	3.0
MV2112	56	150	3.0
MV2113	68	150	3.0
MV2114	82	100	3.0
MV2115	100	100	3.0

Motorola MV2000 varactor diode family. At 90¢ each, these diodes should appeal to many amateurs.

Fig. 3 but one can always send to the manufacturer for the specific curve for any diode *(Motorola Semiconductors, McDowell St., Phoenix AZ 85001)*. The tuning ratio refers to the capacitance variation between the bias voltage stated. This drops as the capacitance value increases but any of the diodes would be suitable for HF application. The smaller capacitance diodes would still be useful into the VHF range. If the Q is 300 at 50 MHz, it would drop to 30 at 250 MHz, etc. Table II shows the essential characteristics of the smaller family of diodes available from Eastron Corp. at $1.50 each (except for the VC6204 which is $1.80). Eastron will sell directly to amateurs, postage prepaid. Write to *Bill Slusher, WIZYX, Eastron Corp., 25 Locust St., Haverhill MA 01830.*

Shaping the Capacitance Variation

Suppose one wanted to construct a really good 5 MHz oscillator for use with an existing transceiver so one could achieve independent receiver and transmitter tuning. Many transceiver manufacturers offer such separate oscillators but unfortunately their cost runs easily over $100 and can represent a significant fraction of the original transceiver cost. Building such an oscillator as a home-brew project can represent a very cost-savings project and yet not lead one down any too difficult paths. Also, there is no danger of incorrect operation on out-of-frequency segments of a band because the home-brew oscillator is only used for receiver tuning.

By searching through past issues of various amateur radio magazines one can find many excellent circuits for transistorized 5 MHz oscillators. One can also of course just duplicate the circuitry of the oscillator found in an existing transceiver, if the oscillator appears stable enough. Duplicating the actual circuitry of an oscillator usually presents no great problem. The problem develops when one considers how to duplicate the mechanical tuning aspects of the oscillator where a dial mechanism allows linear readout to 1 kHz segments, etc. The use of varactor diodes can greatly simplify this problem if one can develop the oscillator circuits such that the oscillator frequency as a function of bias voltage applied to the varactor diode used to tune the oscillator has a linear relationship.

The simplest case is if one chooses an oscillator circuit where the frequency output is linear with the capacitance variation of the capacitor used to tune the oscillator circuit. In this case, the varactor diodes capacitance variation has to be linear with the bias voltage change applied to it. There are two ways to achieve this effect. The simplest is to vary the bias voltage across the varactor only over a range over which the capacitance variation remains linear. For instance, in Fig. 5 varying the bais voltage from −10 to about −4V produces an almost perfect linear capacitance variation. Varying the bias voltage over a smaller range of from −10 to −8 or to −6V in Fig. 4 produces a similar linear effect but the capacitance variation is rather small and would only suffice for oscillators designed to cover a 100–200 kHz segment of a band at a time.

The second way to make the capacitance variation of the diode linear with applied

bias voltage when it is not inherently so is to use a voltage shaping network for the applied bias voltage. As was mentioned before, the voltage versus capacitance variation of a diode does not match the taper of any potentiometer. Therefore the shaping network must be arranged to use a linear taper potentiometer with an auxiliary network to change the bias voltage at points where its linear variation deviates too far from the non-linear variation of the diode's capacitance/bias curve. In essence, one tries to match a number of straight line segments to the changing curve of the diode characteristic.

The procedure is not difficult especially if not too great a capacitance range is desired. A simple example will be used to illustrate the point. For instance, if the diode shown in Fig. 3 was desired to be used such that its capacitance change with bias supply voltage change (as supplied by a linear taper potentiometer) was desired to be linear over the approximate capacitance range of 30–50 pF, the shaping circuit of Fig. 6(A) is used. The diode has to be biased from both "sides" rather than having one side grounded because the capacitance variation of the diode changes most rapidly at low bias voltages *across* the varactor diode. This point will become clear if one follows through on the example. With the circuit shown and until the variable bias voltage exceeds 6V, the 6V fed through a switching diode can be considered to be out of circuit. So, as the variable bias voltage varies from 0 to about 6V, the voltage across the varactor is 12V (fixed bias values minus the variable voltage). The capacitance can be plotted as shown in Fig. 3 (dashed line). In this case, the "bias, volts" line on the graph represents the value of the variable bias voltage and *not* the voltage across the diode. When the variable bias voltage exceeds about 6V, the diode in the 6V bias line is forward biased and conducts. As the variable bias voltage now increases, its rate of change is determined by the voltage divider network formed by the two 100K resistors. The bias voltage across the varactor diode for any given value of the variable bias voltage can be found by simple ohm's law calculations

(remember that the varactor diode is never conducting). The plot of variable voltage versus capacitance is shown by the dashed line in Fig. 3 and found to be quite linear.

The bias voltages shown in Fig. 6(A) may appear numerous but they are all easily obtained from one supply using dropping resistors and zener regulators. The shaping network values can be determined by trial and error to obtain the most linear response. As an approximation for the intermediate bias value (6V in Fig. 6(A)) take the bias voltage necessary to achieve a mean capacitance value for the total capacitance range desired. In the example, the total range was 30–50 pF, making 40 pF the mid value for which the required bias voltage (from Fig. 3 solid line) is 6V. The resistor in series with the variable bias voltage should remain 100K and one can then try differenct values for the resistor in series with the intermediate bias voltage to obtain the most linear response. A few plots on graph paper will quickly reveal the best value.

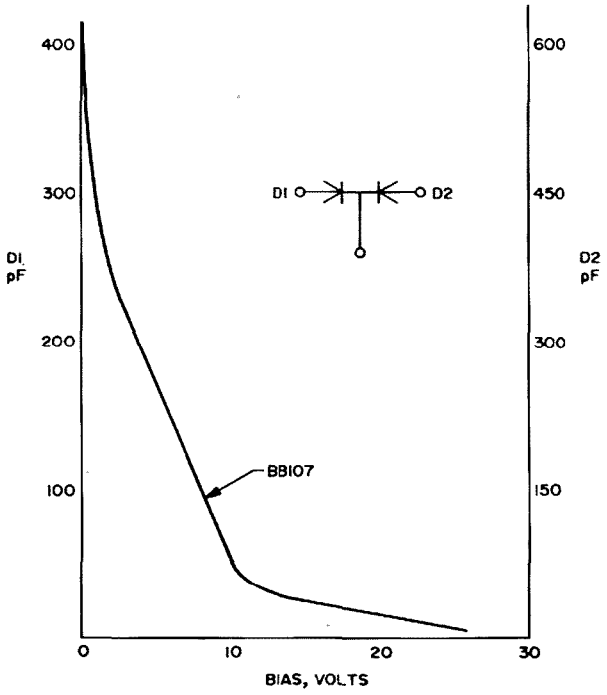
If one desired to make the capacitance variation linear with variable bias voltage over a larger capacitance range, it can be done by the circuit of Fig. 6(B). The circuit works on the same idea as the simple shaping network just described. It appears a bit more complicated but is actually quite economical since each intermediate bias voltage is obtained from one source via zeners. Extremely linear capacitance variation can be obtained over at least a 100 pF range, depending upon the diode involved.

Rather than describe in detail here the procedure for calculating all the bias voltage involved, it is suggested that the reader sent for Application Note No. 6 from Eastron Corp. If one has a capacitance measuring bridge, excellent results can be obtained by first making each bias voltage variable via a potentiometer from the main supply, measuring the capacitance variation for different settings, and then finally using zeners for the intermediate bias voltages.

Frequency Shaping

The above procedure has described how to make the capacitance change of a varactor linear with the variable bias voltage. However, one may have an oscillator circuit where the frequency output is not linear with the capacitance variation in the oscillator tank circuit to begin with. In this case, frequency shaping via the varactor diode bias can be done and, in fact, represents one of the major advantages of using varactor diodes for capacitance tuning. A linear *frequency* output can be obtained with a fraction of the effort required using elaborate mechanical tuning schemes, special oscillator coils and air variable capacitors, etc. This feature can also be combined with a very simple readout scheme for frequency settings.

Frequency shaping is obtained in basically the same manner as the linear capacitance method. However, in this case, a graph similar to Fig. 3 is drawn which represents oscillator output frequency (instead of diode capacitance) versus bias voltage supplied to the diode. The output frequency of an oscillator being built can be monitored on any available receiver or transceiver. Once the curve is drawn, a shaping network similar to that previously described is calculated so that the oscillator output frequency versus bias voltage applied to the diode has a reasonable linear



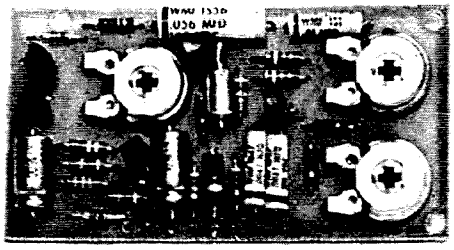


Fig. 5. Response of an unusual but handy dual tuning diode made by Siemens in Germany and available in the U.S.

WORK FM REPEATERS?

If so you probably already know that having the correct CTCSS tone in your rig is pretty important these days. If you're still wondering where to find a quality, reliable tone burst generator, the answer is the UNIDYNE TBG-102

- SOLID STATE, TOP GRADE COMPONENTS; EPOXY GLASS PCB.
- REQUIRES NO BATTERY, INTERNAL REGULATED P/S FOR 10-30V.
- FREQ. RANGE 1450-2450 HZ. SPECIFY TWO FACTORY PRESET FREQUENCIES WHEN ORDERING.
- BURST LENGTH 100 MS. – 5 SEC. OR CONT. TONE. FACTORY SET 1/2 SEC.
- H GH AND LOW IMPEDANCE OUTPUTS; USE WITH ANY MIC.
- SIZE 3 1/8 x 1 3/4 x 1/2 INCHES. INCLUDES MOUNTING HARDWARE.
- EXTERNALLY PROGRAMMABLE FOR ANY NUMBER OF FREQUENCY, AMPLITUDE AND LENGTH PRESET COMBINATIONS.
- COMPLETE INSTRUCTION MANUAL. FACTORY WIRED AND TESTED $19.95

UNIDYNE TBG-102 KIT $14.95 POST PAID.

ALSO AVAILABLE . . .

COMPATIBLE DECODER unit contains notch filter to prevent annoying tone burst input from being retransmitted. Fully adjustable range and window for burst frequency, length and amplitude. Carrier logic to prevent repeater drop-out during most signal fades.

REPEATER CONTROL unit complies with LATEST FCC REPEATER RULES including adjustable timers for 3 minute protection and 5 second carrier delay drop-out. Includes COS.

CARRIER OPERATED SENSOR for use with or without relay.

relationship. The accuracy of the shaping network can always be corrected by monitoring on a calibrated receiver.

Once a linear relationship has been achieved between output frequency of an oscillator and bias voltage, tuning of the oscillator via variable bias networks, frequency readout, etc., are greatly simplified. The following paragraphs present only a few ideas. Many more can be developed depending upon individual requirements.

Tuning and Readout Systems

With a linear output frquency/bias voltage relationship for a varactor tuned oscillator, the tuning problem reduces itself to the simple rotation of the linear taper potentiometer which supplies bias voltage to the diode. If the potentiometer rotation through the usual 270° varies the oscillator frequency by 250 kHz, it can be driven via a simple 10:1 gear reduction drive. In this case, each degree of basic potentiometer variation covers 250/270 or .926 kHz per degree. The 10:1 drive means that each 360° rotation of a tuning knob provides 360/10 or 36° of basic shaft rotation. The frequency variation in this case would be 36° X .926 kHz per degree or about 33 kHz per tuning knob rotation. By using greater reduction tuning ratios or smaller basic oscillator frequency coverage (100 or 200 kHz segments), extremely fine tuning can be obtained which easily allows 1 kHz or less readout divisions on the skirt of a large tuning knob. An important consideration is that extremely fine bandspread can be obtained with reasonable gear reduction ratios for the bias potentiometer (10:1, 20:1, etc.) so that the gear reduction drives are both inexpensive and have minimum backlash. One can also switch the bias voltage to a tuning diode between a potentiometer driven via a gear reduction drive and a directly driver potentiometer to provide a fine bandspread tuning or a quick band-scan tuning. The extra cost is only that of a simple potentiometer and only single dc line voltage switching is involved.

Another approach not to be overlooked is that of using multi-turn potentiometers for bias voltage tuning. Such potentiometers,

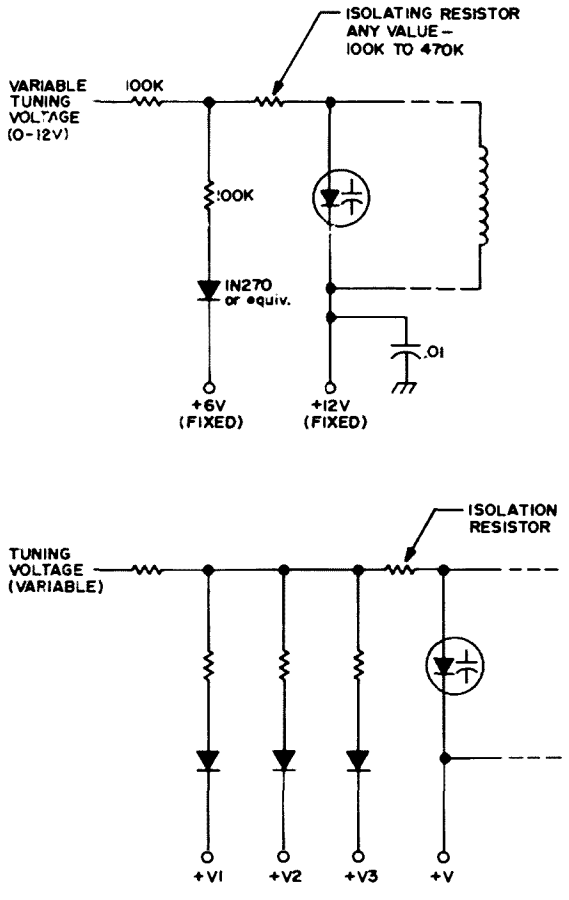

Fig. 6. Simple (A) and complex (B) shaping networks which can be used to "linearize" basically non-linear response of a tuning diode.

usually in the 10 turn variety, are available from a number of surplus outlets (Poly Paks) at a cost of only a few dollars. These potentiometers are of commercial quality and provide excellent resetability combined, of course, with their built-in fine tuning advantage. Such potentiometers when combined with even a simple gear reduction drive provide extremely simple but excellent tuning possibilities. For instance, a 10 turn potentiometer combined with a 6:1 reduction drive means approximately that a tuning knob, for the example previously given, would cover only 6 kHz per tuning knob revolution. This type of extreme bandspread can be achieved without any great mechanical difficulty whatsoever.

Frequency indication can be achieved by the use of relatively simple meter movements. Basically, once the frequency output is linear with bias voltage change a measurement of the bias voltage via any simple voltage meter is directly proportional

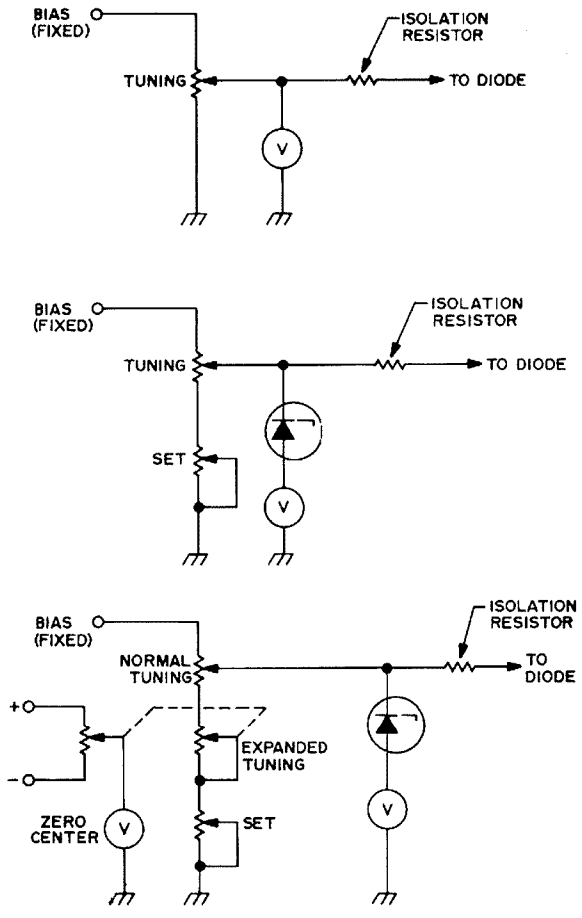

Fig. 7. Various ways of using simple voltmeters as frequency readout devices in conjunction with voltage tuned diodes.

to the oscillator output frequency. The meter can be placed across the bias supply to the diode as shown in Fig. 7(A). The meter scale can then be remarked to indicate frequency, or if the scale is carefully chosen, it might be used directly. For instance, if one is building an oscillator to cover 5.0 to 5.5 MHz and the bias voltage change is 5V to cover this range, the 1V divisions on the meter scale can represent 100 kHz. In most cases, however, things aren't that simply done since the tuning diode is operated over a certain voltage range which doesn't always start at zero. But meters can still be used effectively. For instance, in Fig. 7(B), the main bias supply voltage and the "set" potentiometer are adjusted so the desired range of bias voltage is available at the potentiometer which tunes the diode. Say, a range of 4–9V is used to keep within the linear range of the diode shown in Fig. 5. A 0–5 scale voltmeter can still be used by placing a zener diode of 4V in series with it to form "voltage expander" scale on the meter. One should refer to an article on meter scale changes possible via zener diodes to learn of various other possibilities, all of which are too extensive to cover here.

Perhaps one last example of the versatility possible with various tuning arrangements with diodes is worth while. In tuning an auxiliary oscillator which provides independent receiver tuning for a transceiver, suppose it is desired to have one tuning control which tunes the oscillator in a normal fashion with reasonable bandspread but, in addition, have another tuning control which electronically "magnifies" any small tuning area around that to which the main tuning is set. In other words, the main tuning may cover 30 kHz per knob revolution but the auxiliary tuning takes any frequency to which it is set and expands it either lower or higher in frequency at the rate of 5 kHz per knob revolution. The circuit for doing this is shown in Fig. 7(C). The resistance range and gear reduction drive (if used) on the expand potentiometer is chosen to vary the oscillator frequency any desired small amount. The other potentiometer gauged to the expand potentiometer simply drives any center zero meter so one can return the expand potentiometer to its center position easily before using the main tuning potentiometer again. The scale on the zero center meter can be calibrated in terms of frequency change, plus and minus, if desired, but the indication on the main tuning meter also changes when the expand potentiometer is used so there is never any doubt as to in which direction the oscillator frequency is being changed.

Summary

The ideas presented here are only a few that can be applied to the use of tuning diodes. Other bandspread schemes, automatic band scanners via a triangular voltage to drive the diodes, quick switching between bands for spot checks, and many more are readily possible. The main advantage is that these varied tuning possiblities can be done with simple components at very reasonable costs and an available receiver or transceiver with good calibration used to align the necessary circuits.

LETTERS

Subject: the cover on the 73 October magazine. My husband has numerous magazines coming into our home with *acceptable* covers. Mr. Shera DOES NOT buy magazines with *unacceptable* pictures. I object to your putting that unacceptable cover on the 73 magazine and sending it into American homes where there are men who choose to live without feeding on adulterous thoughts.

Mrs. Philip Shera
Kansas City MO

How did you like the November cover??

Really enjoy your magazine, would like to see more articles, 200 MHz and above and SSTV. But I would subscribe anyway just for the cover!! "OCT 72 COVER TERRIFIC"

Jess B. LeBow K8LJQ
Pinckney MI

73 still the *greatest – far* superior to all others! Cover on current issue here has to be the best yet. Keep up the fine good work!

Stan W4VMR
Valparaiso FL

Your October 73 cover is by far the finest I have ever seen. From one who studied art, loves the outdoors and amateur radio, and is a normal male, Mary Jane Trokel is a shapely, pleasant personality, merged with a healthy outdoors and a healthy hobby. In short, the cover is very pleasant and in good taste, and she would make any artist want to paint her in oils.

For summer, how about a cover of her in a bikini with the radio controls for a model boat, or perhaps at the helm of a boat using 2-way radio communication?

Also, how about a cover in color of your pretty and shapely wife? She certainly deserves the honor for putting up with one of us nuts.

I hope the beautiful October color cover sets a precedent for future issues, and please keep the ham-built construction articles coming.

Zoltan T. Bogar
Silver Spring MD

In a recent issue one of your readers stated that Pete Stark K2OAW, did not answer his mail. I must be living right, because he sure answered my request.

I put in a request for the layout of his VHF frequency counter. It required a SASE. By habit, I put Canadian stamps instead of U.S. stamps. Pete put his own stamps on the return envelope and mailed it anyway!

There is the possibility that your reader's letter might have gotten lost in the mail. If hegivesPete another try, I'm sure a reply would be forthcoming.

Tom Webb WA9AFM/VE8
Winnipeg, Man., Canada

This letter is in response and a rebuttal to the letter written by (W1JSS) a Mr. Dineen, as published in 73, the Sept. issue, in which Mr. Dineen complains about the bad cooperation on the part of the author of an article which was published in your magazine, and the author is Mr. Stark (K2OAW).

I, for one, disagree wholeheartedly with W1JSS, as to the response from K2OAW. Mr. Dineen does not evidently know what he is talking about and I say this from experience with K2OAW. I was as dumb as they come when it came to the solid state IC's. I knew you put them together and you expect them to work, everything is fine up to this point, but when I got into trouble, I did not know where to begin to look for my solution and I did not know what the different functions of the different IC's were. At this point I wrote Mr. Stark, explaining my problem, and by return mail he explained quite a few things, and since then I have had the occasion to write Mr. Stark on different problems and he very patiently answered all of my letters very promptly, in fact if the tables were turned around and he was asking me the questions, I would be tempted not to reply, but not Mr Stark, as he has spent quite a bit of time and money to help me and what I know now about IC's, which is quite a bit, I owe to the patience of Mr. Stark. For the record, I have been a ham since 1925, so you see I am not a novice at this game.

J.J. Daris K9VKD
Sterling ILL

WA9TCR's letter in the October issue prompts me to write this letter. I have just rejoined ARRL after a lapse of about 8 years. I dropped out in protest of their speaking in my name without my knowledge in their representations to the FCC. HQ claims to speak for so many thousand amateurs and the only way to dispute it is not to have your name on their list. However recently I decided maybe now there is enough of a movement going that a voting membership could help.

Here is my request. Please introduce a regular column devoted to ARRL news. I am sure you have contacts the rest of us don't have and would be able to publish what QST doesn't. I realize you do this on an irregular basis. This would include a rundown on the directors when they come up for election. In the past I have voted but really they were just names on the ballot and information about them was just hearsay. I and I am sure a lot of others would like to use our vote intelligently. Huntoon won't like it but that shouldn't scare you off, how about helping us?

I think a regular feature or section in your editorial each month would be best so we don't overlook it.

Orbra W. Bliss W9GEK/EL2N
Verona WI

Sounds like a good idea. Maybe we could run a regular ARRL column in the newspages each month to report the behind-the-scenes action at HQ! If anyone has any interesting information that he feels the rest of us should know about, send it in and we will gladly pass it along to the rest of the world.

Sometimes I wonder why you don't reprint some of the extra good "oldies." I appreciated "Mobile Power – The Alternator" and "Solid State Regulator" both in Aug. 1967 issue. With so much mobile activity, keeping your battery "up" should be of prime importance.

Neil W20LU
Tappan NY

It is important! Just think of all the OMs out there with dead batteries . . . just because they didn't cash in on our back issue bonanza offer with a subscription renewal.

bands from 2 to 2300 MHz (for increased resolution, the reverse power element is ten times more sensitive than the forward power element). Model 4342 Insertion VSWR in 50Ω systems is a low 1.035 to the point of measurement. A choice of QC Quick-Change connectors permits mating with N, BNC, TNC, UHF, C, SC, LC, HN, LT, GR Type 874 and 7/8" EIA lines without the need for performance-degrading adapters. The price is $265, with plug-in elements ranging from $30 to $75. Contact the *Bird Electronic Corporation, 30303 Aurora Road, Cleveland (Solon) OH 44139.*

TWO METER 18 WATT AMPLIFIER

Herman Cone III, WB4DBB
1320-12 Kings Arms Apts.
Chapel Hill NC 27514

This amplifier is designed to be driven with power levels slightly less than is available from many solid state FM transceivers. The RMV transmitter puts out 5 watts, and one can easily get 18 watts of output when using it with this amplifier. Other lower power rigs (3–6 watts) work well, but do not drive it with more than 6 watts.

The amplifier is built on a piece of double sided glass epoxy board and all the foil is left in place except for the thin areas surrounding the seven pads, which are used for solder joints. All leads should be as short as possible. All five trimmers should be soldered directly to the board. The mica compression type work well and are available at most electronics dealers. They are relatively inexpensive, too.

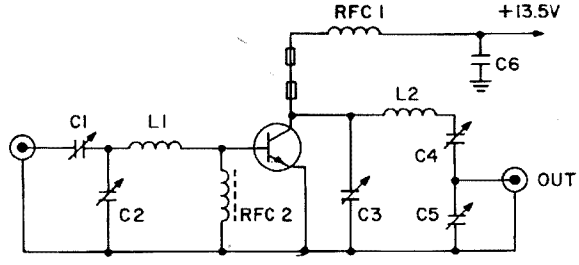

Fig. 1. Circuit of 18 watt amplifier.

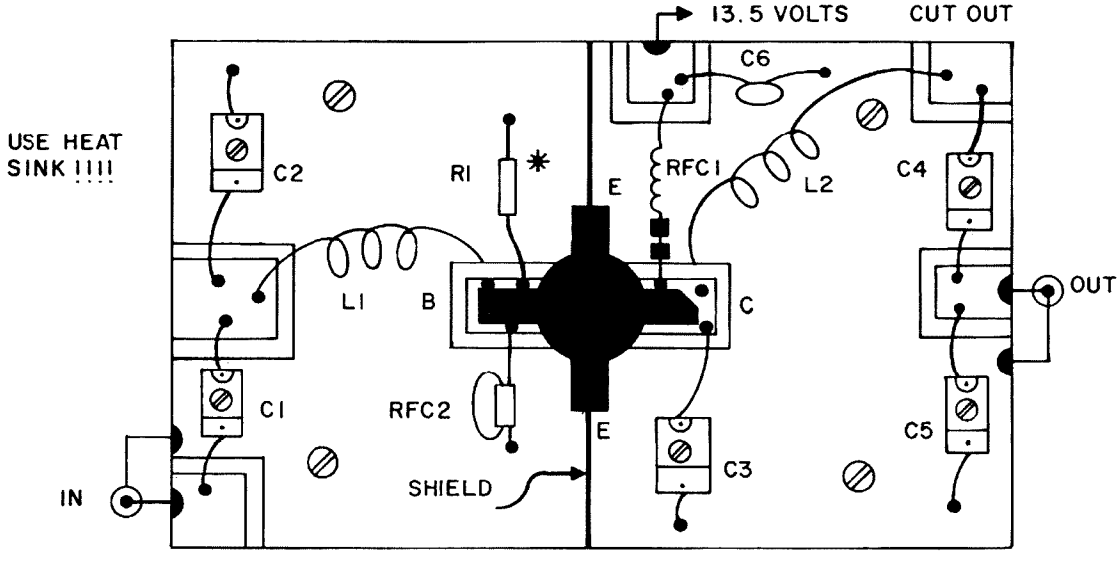

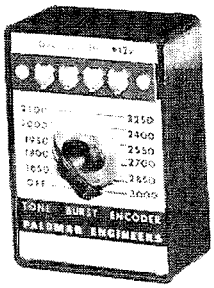

Fig. 2. Full size circuit board showing parts placement. Components mounted on copper side.

TONE BURST ENCODER

- *New! Eleven tones in one encoder.*
- *L-C oscillator. Stable - no R-C circuits to drift.*
- *No batteries needed.*
- *Full one year warranty.*

- *Now, all the popular tone frequencies in one encoder. Panel switch selects 1650, 1800, 1950, 2000, 2100, 2250, 2400, 2550, 2700, 2850, 3000 Hz.*
- *High and low impedance outputs - works with all transmitters. Level adjustment provided.*
- *½-second tone burst time also adjustable. Continuous tone if needed.*
- *Free descriptive brochure on request.*
- *Order direct. Price $37.50 PPD USA (5% tax Calif.)*

AN-TEK INDUSTRIES

Box 357 R. R. 5 Elkhart, Indiana 46514

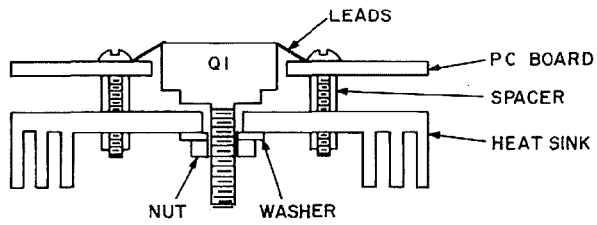

Fig. 3. Side view of heat sink mounting.

Care should be taken when mounting the transistor. First, prepare the board by making the pads and drilling a hole for Q_1. Then mount the board to the heat sink (use a big one) with 4 screws and spacers. Then mount the transistor, using a good heat sink compound. Be sure not to overtighten the transistor's mounting nut. Now, after the board and transistor are secure, solder the 4 leads in place. Both emitter leads go to ground. Then solder the shield (metal or PC board) over the transistor so that it is vertical. Be sure to cut a notch in the shield so that it clears the transistor.

To tune the amplifier up, start with reduced voltage (8–9 volts) and low power (1–2 watts). Tune the trimmers for maximum output. If instability is noticed, you may need to add R_1. When operating properly, the amplifier should provide 5–6 dB of gain with 13.5 volts.

PARTS LIST

SIDEBAND SNIFFER

Years ago when one modulated an 813, pair of TZ40's or whatever, it was nice when testing seemed called for to get a hearing of one's own transmission. This needed nothing more than a diode, pick-up loop of a few turns, and a minimum of other items, Fig. 1. At first I used to put audio into the TX mike circuit from another af source. Later, I used to put the diode output into a tape recorder, and afterwards listen for a minute or two to this reception of the TX signal.

With CW, you can do a similar thing, rf from the TX activating a tone generator.

With the change to SSB on some bands, and separate TX and RX, the latter could satisfy the question about whether the outgoing signal was intelligible, provided rf into the receiver was kept well down, and rf and i-f gains were at minimum.

With the advent of the transceiver, there was alas no handy means at all of making easy checks of what other people were hearing. The SSB Sniffer shown here was built to overcome this.

Method of Working

In the interests of stability, the Sniffer works on one crystal controlled frequency only. The frequency can depend on what old crystals are on hand. Figure 2 is the complete circuit of the Sniffer or spot frequency sideband receiver, which is what it really is. Here, the crystal oscillator is on 3.55 MHz. Its output and a bit of SSB from the transmitter go to the twin diode product detector. The audio output goes to a tape recorder, af amplifier or to headphones.

It is handy to have the Sniffer on a favoured band. If lengthy tests are to be made, it is only fair to put the TX output into an artificial load for their duration. Otherwise eavesdrop on a bit of your own transmission or QSO.

If the transmission sounds satisfactory on the Sniffer frequency, there is every reason

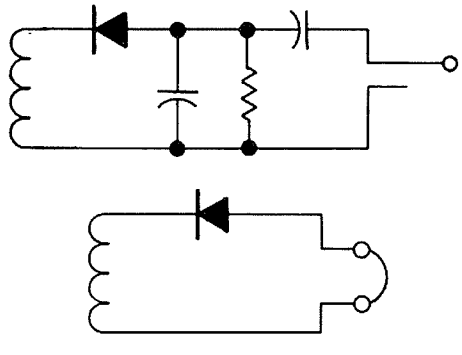

Fig. 1. Simple monitors for checking modulation.

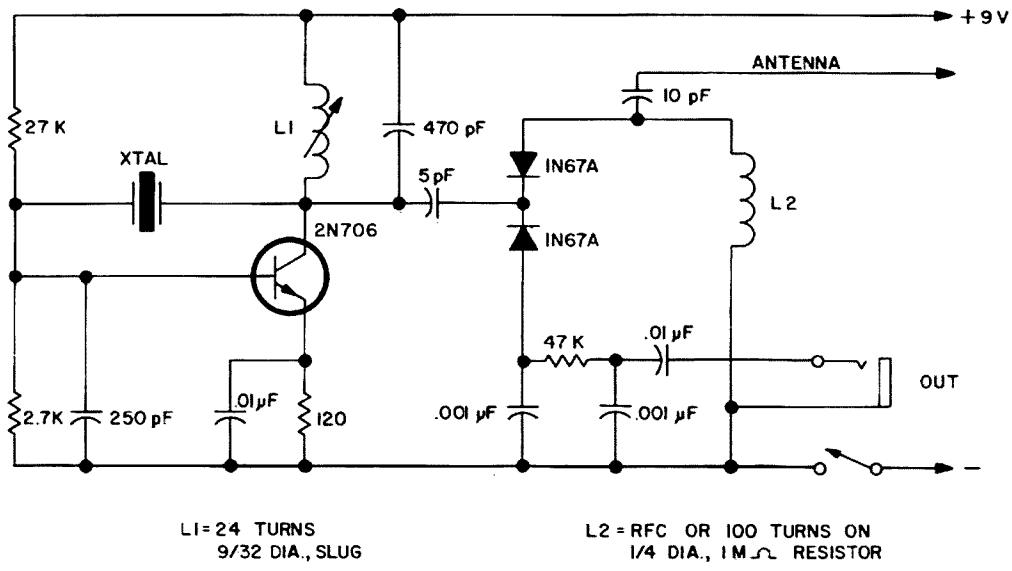

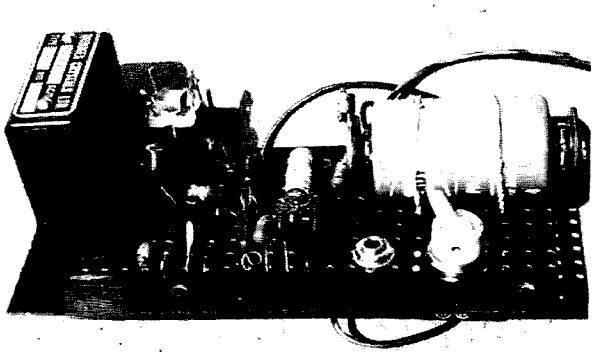

Fig. 2. Circuit of the SSB Sniffer.

for supposing it will also be satisfactory on other frequencies or bands – provided you duplicate conditions of correct PA loading, drive, PA meter peak readings and voice level or mike gain. After all, if you ever used Fig. 1 with a grid modulated PA or other touchy AM circuit, you did not need to make a new check every time you changed frequency.

Building It

The circuit can be wired on any suitable piece of insulated board, the photo is a layout plan for anyone requiring this.

For 80Ω crystals, L1 is 24 turns of 32 enamelled wire, on a 7mm or 9/32" diameter former with adjustable slug, and has a 470 pF parallel capacitor. Some other L/C combination which will tune up would do as well. With a 9V battery, current was about 1 mA with no oscillation, rising to 4 mA with the slug adjusted for maximum oscillation. Need it be said that nothing can work if there is no oscillation.

The 10 pF capacitor is not an isolator, but gives some protection against shorts. Place the "TX" lead near the artificial aerial load, coupler, or aerial circuit somewhere, so that the transceiver S-meter reads about S9 with the gear at receive, and tuned to the Sniffer frequency. (This does not apply with a separate TX, where you naturally provide some rf pickup from the TX to the Sniffer.)

Now switch to transmit, and make the appropriate adjustments to make gain, grid drive, PA tuning, and loading. You may have to adjust the transceiver tuning minutely one way or the other, since you can't tune the Sniffer, and you should in any case move the Sniffer antenna to get a suitable level of rf pickup, as shown by best results. Be sure not to get too much SSB into the Sniffer – this will produce a result sounding like grossly overmodulated AM.

CRYSTAL FREQUENCY AND ACTIVITY CHECKER

The crystal checker described here evolved from an idea by W2OZH in and old issue of *Hints & Kinks*. It has gone through several stages of refinement, which is usual with homebrew gear. A more sophisticated version is now on the drawing board. Besides checking crystal activity, it measures the difference in frequency of two crystals up to 30 kHz. This difference frequency is read directly on a meter.

Figure 1 shows the circuit diagram. The circuit consists of two identical Pierce oscillators which work in the range of 3–9 MHz using a 6J11 tube. The input capacitance of each oscillator is 32 pF which seems to be the standard for FT-243 crystals. The output of each oscillator is coupled to a 12AT7 mixer stage. The output of the mixer, which is the difference frequency of the two crystal oscillators, is fed to a 6AU6 limiter which presents a square wave signal of constant amplitude to a counter circuit consisting of a meter, two diodes and associated capacitors. A function switch puts the meter in the grid circuit of either oscillator for checking activity. In the center position both oscillators are on, the counter circuit switched in and the difference frequency read on the meter. A range switch selects ranges of 30, 10, 3 and 1 kHz. These were chosen because the meter available was calibrated in these scales. Other ranges should work equally as well, possibly up to 100 kHz.

Construction layout is not particularly critical except that the two oscillators should be symmetrical. As seen in the photo, the counter circuit is built on a sub chassis. This is not necessary – in fact it would facilitate servicing if all components were mounted on the same chassis. The transformer T_1 is used in reverse to provide a better impedance match and more drive.

The capacitors in the counter circuit are critical and the values were determined by "cut and try." If you use different ranges from those shown, the values given will

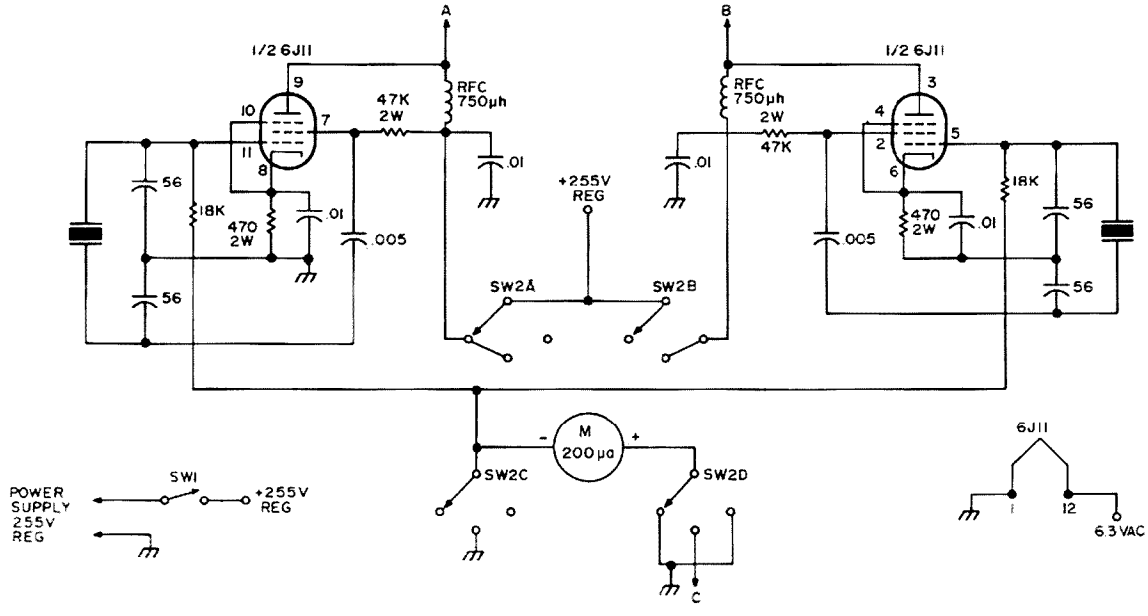

Fig. 1. Circuit diagram of the crystal frequency and activity checker using two identical oscillators.

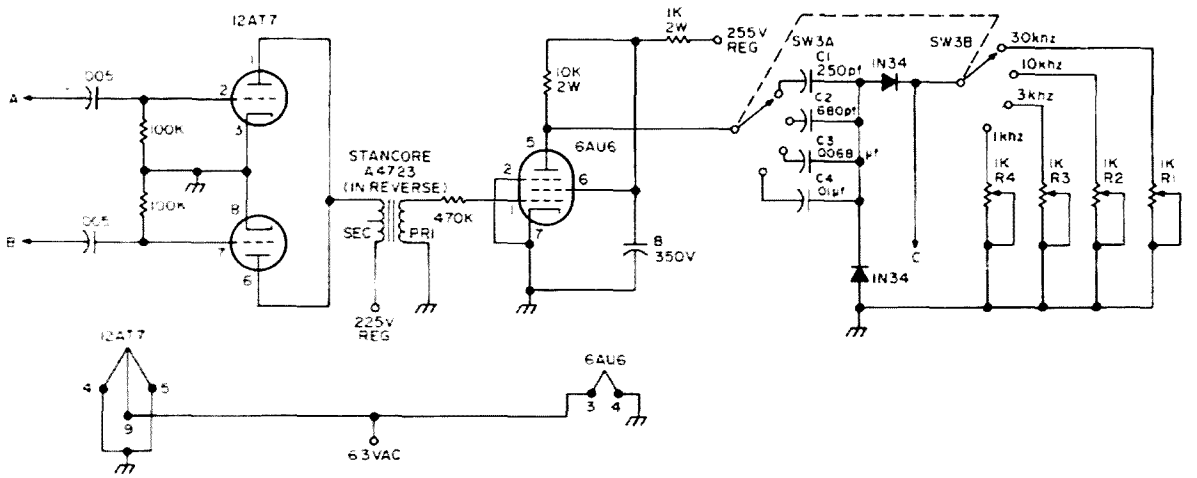

Fig. 2. Circuit of the mixer and limiter stages.

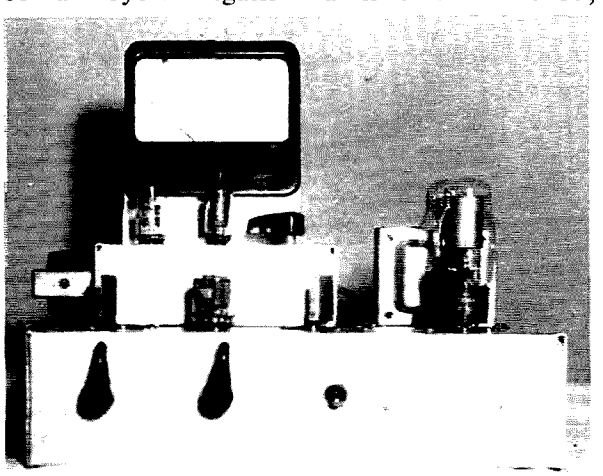

provide a starting point. Use good quality condensers. A little extra investment here will pay off in added accuracy.

After double-checking the wiring, test the oscillators first. Insert a crystal of known good activity in one oscillator. With crystals in the 7–8 MHz range the 200 μA meter should read half scale with the components and voltages shown. Now check the other oscillator. It should give the same reading. If it does not, it is likely that the two halves of the 6J11 are not equal. In this case, adjust the grid and/or cathode resistor in one oscillator to achieve the same readings with the same crystal. The frequency should remain the same with either oscillator.

There are several different ways to calibrate the counter circuit. One simple method is to use four pairs of crystals with exact frequency separation of 30, 10, 3 and 1 kHz. Frequencies outside the ham bands in the 6–8 MHz range will work fine and can be secured at an economical price from surplus dealers. First, use the pair that is exactly 30 kHz apart. With the range switch set for 30 kHz and the function switch in the frequency measuring position, adjust R_1 (the meter shunt) for full scale reading. Now the frequency separation of any two crystals can be read directly on the meter scale, up to 30 kHz. The other ranges can be calibrated in the same way.

Another method of calibration is to use an audio oscillator which is accurate and which will work up to 30 kHz. Feed a signal in at point X which has been disconnected from the transformer. The mixer tube should be removed. Set the audio oscillator at 30 kHz with full output and adjust R_1 to full scale reading. The limiter can now be checked by reducing the audio oscillator output to a point where the meter just begins to drop off. This is the threshold point and the audio oscillator output should always be above this point in order to present a constant amplitude signal to the counter circuit. Now move the audio oscillator to 20 kHz and then to 10 kHz, checking the meter on the 30 kHz scale. If the readings are not linear, adjust C_1 up or down for linearity over the entire scale. The other ranges can be calibrated in the same manner.

Caution: When measuring the frequency of a crystal against a known standard,

The crystal checker. Controls left to right: On-off test, function switch, ac on-off.

remember that the output of the mixer is the *difference* frequency so it must be determined if the frequency is above or below the known standard. For example, the known frequency is 7150 kHz and the meter reads 10 kHz. This can be either 7160 kHz or 7140 kIIz.

If, after calibration, the crystal checker does not agree with readings taken on a BC-221 frequency meter, the BC-221 may be suspect. If it is several years old, the spread between check points in the calibration book may be too great. The military instruction book says that check points should be within 1.8 dial divisions on the low band and 1.2 on the high band. This error is not too great when using the fundamental range on the high band but becomes quite significant when multiplied four times. A wide difference in check points is caused by aging of components. One solution is to feed a 100 kHz crystal calibrator (which is zero with WWV) into the BC-221 with its 1000 kHz oscillator on in the "check" position. Many more check points can now be heard. For example, you will hear a check point at 7150 kHz, which would not otherwise be readable. Always choose a check point as close as possible to the frequency being measured. The accuracy of the checker is only as good as the accuracy of calibration so close attention to this is highly recommended.

This instrument has been in daily use here at W4AYV for over a year and the performance has been most gratifying. It would be especially useful for those doing any serious work with crystal SSB filters. For instance, it is possible to more nearly match crystals for zero separation than listening on a BC-221 or receiver. For such jobs only one frequency range would be needed, perhaps the 5 kHz range. This would simplify construction and calibration. In fact, for just matching crystals, no calibration is necessary. It is indispensable when etching crystal blanks for filters. A separation of, say, 1.8 kHz can be read precisely which beats trying to measure such separation on a BC-221.

10 AMP VARIABLE POWER SUPPLY

This power supply grew out of the "Versatile Variable Power Supply" described by W6SLP in the June 1968 issue of *73*. That circuit used a capacitive multiplier feeding two germanium type 2N1970 power transistors wired to adjust the output voltage to any desired level. I found several difficulties in his circuit. First there was no way that his capacitive multiplier could supply power to the output transistors when the pulsating dc from the bridge was at an instantaneously low potential. Also that extra filter circuit in series with the high current dc path caused an undesirable extra voltage drop. The 2N1970's in the dropping circuit had a tendency to leak badly under heavy loads. When they leaked too much the output voltage would rise – and the output current would rise – and the temperature would rise – and the leakage would rise – and so on to terminate in a well known result. After two of the 2N1970's rediffused themselves all over the inside of their cases, I decided that this supply just wasn't going to hack more than just a small load.

The supply that I built is a legitimately regulated dc supply that is capable of up to 10 amps at any voltage between 2 and 36 volts, and still remain in one piece. Ripple and noise is less than 10 mV at full load and the output voltage drops off less than ½ volt from no load to full load. It is built of the least expensive and therefore least exotic parts that I could dig up. Many of the components can be found in surplus stores at much less than their catalog prices.

Theory of Operation

This supply uses two silicon power transistors, Q3 and Q4, in a series regulator circuit. They are fed by a full wave bridge and a large filter capacitor. Q3, Q4, Q2, and Q1 form a triple Darlington with a gain of about 400,000 at 10 amps.

Q5 and Q6, along with a few other components, form the error amplifier circuit. These two transistors sense the output voltage and adjust the bias on the regulators so that the output voltage maintains a preset level. Any change in loading on the supply is fed back out-of-phase so that the regulators will compensate for it. Also any input change, including hum, is virtually eliminated by the regulators.

C2 provides a nearly pure dc voltage for the error amplifier. D5 allows C2 to charge from the power path but does not allow it to discharge back. In this way only the small load of the error amplifier is placed on this capacitor. R2 prevents D2 from blowing up when the supply is turned on. R3 provides the collector load for Q5 and will dissipate a little over two watts when the supply is set to a high output voltage.

R4 and R5 balance the current between the two regulator transistors so that one of them will not hog all the current and run too hot. The 10 amp fuse, F2, is there to protect the regulators against a not-too-drastic overload. It probably won't help if the supply is shorted good and proper. One of the regulators will probably succeed in protecting the fuse.

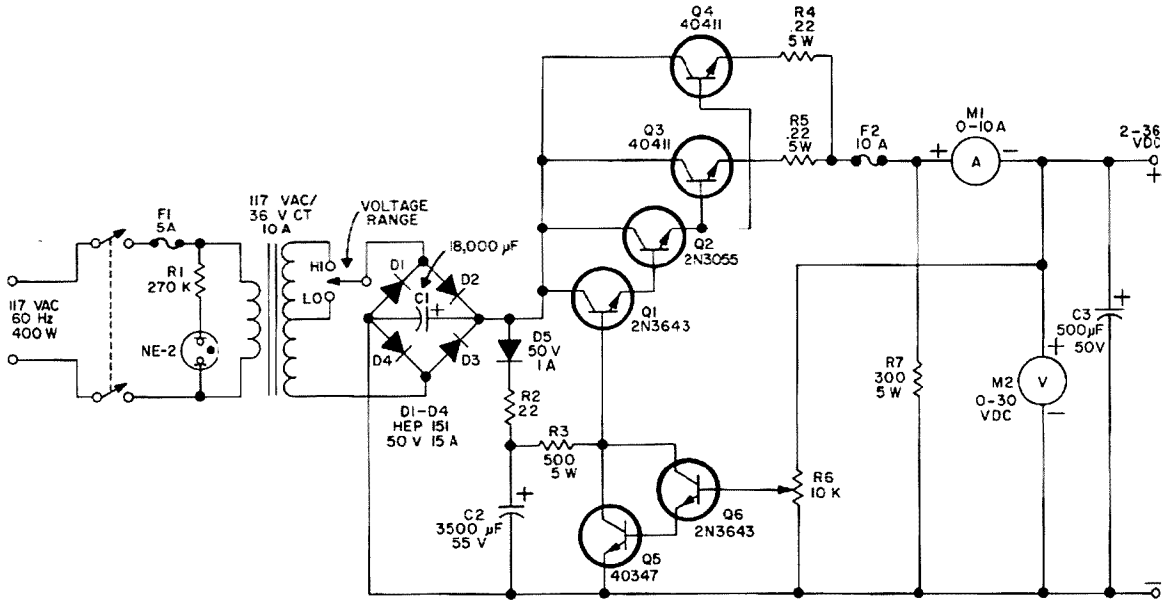

Fig. 1. Circuit of the 2-36V, 0-10A variable power supply.

R7 is a bleeder to keep the output voltage down to about 2 or 3 volts when the voltage control is set to minimum. Any residual output above 2 volts is caused by leakage in the regulators or their drivers.

The voltage control pot is connected to the output connector so that any voltage drop caused by R4, R5, F2, or M1 is compensated for by the regulator.

C3 is to help drop the output impedance of the supply and to provide some transient protection for the supply.

The Design

I have found that a regulated supply can provide about the same dc output voltage as the rms voltage rating of the transformer at full load. The transformer can have the same current rating as the supply is supposed to have and it will behave just fine. With a 35 volt surplus transformer wound with #12 wire, a full-wave bridge, and an 18,000 μF capacitor bank, I could get 47 volts no load and 38 volts minimum at a 10 amp load. This meant that at full load and a 35 volt output, my regulators, Q3 and Q4, could drop no more than 2 volts. I found that the RCA 40411 or the type 2N3772 were two of the few silicon power transistors that would do the job and still not cost too much. These types are rated at 150 watts and 30 amps and cost about $4.25 each. Two in parallel provide all the power dissipation that is required. A type 2N3055 would work for the regulators, but I don't recommend this. They are rated at 115 volts and 15 amps but their $V_{ce(sat)}$ is too high at high currents. $V_{ce(sat)}$ at 5 amps is about 6 volts minimum. This limits the maximum output voltage of the supply to about 30 volts. The 2N3055 has one big redeeming characteristic, however, its cost is half that of the others.

The regulator driver, Q2, should have a low saturation voltage at about 300 mA. A 2N3055 will work here as it behaves better at lower currents. You can use a lower power device than the 2N3055 here as it is never called upon to dissipate more than 15 watts. Just be sure that it has a high collector current rating so that the regulators will not starve for base current.

The regular pre-driver, Q1, can be almost any signal type as long as it has *low leakage.* I_{ceo} should be less than 1 μA, and it would help if the transistor has high gain. A 2N3643, available from Fairchild at about $.50, or a 2N1613, available from just about anybody at $.75, will work well.

The error amplifier, Q6, can be the same as Q1. It should also have low leakage.

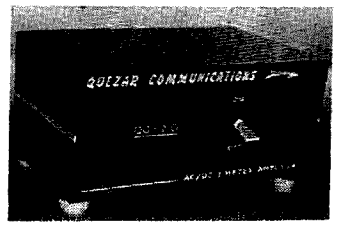
I had surplus rectifiers in the bridge, but a funny thing happened when I tried to discharge the filter capacitors with a screwdriver with the power still on. Where I had had four rectifiers, I then had three bolts. One rectifier managed to survive. I replaced the surplus jobs with HEP 151's. These work

very well although they are running right at their voltage rating. They cost $.79 each. A HEP 152 might be a better idea because it is rated at 200 volts, but they cost about $1.25.

When the supply is used at high currents and low voltages, the regulators have to dissipate the most power. At a current of 10 amps and an output of 10 volts or less, the regulators have to dissipate 300 watts or more. This is very rough on the supply but it can handle it. When low output voltages are desired, it is better to use a lower transformer voltage and keep your electric bill down. By hooking the supply to a lower tap on the transformer, such as a center tap, the supply will still work just the same up to 15 volts or so and it will remove 200 watts of dissipation from the regulators. The supply should be turned off and the filter capacitors discharged *before* the voltage range is changed. If you don't do this, you may be buying some more rectifiers. The switch should be capable of handling 10 amps.

Construction of the power supply isn't critical except for a couple of things that are quite important. Any wires that carry the heavy output currents should be at *least* #16 and should be as short as possible. This especially applies to the ground wire. Also Q3 and Q4 should be mounted on *large* heat sinks and the heat sinks should be mounted on the *outside* of the cabinet in a location where they can have excellent ventilation. If possible the fins on the heat sinks should be vertical so the heated air can flow up past the heat sinks with little difficulty. Q3 and Q4 must be mounted with good silicon grease, and, if possible, the heat sinks should be electrically floating and the mica washers eliminated.

The voltage control pot I used has a linear taper, but a reverse audio taper would work better if you can find one. The value is not critical, any value between 5K and 50K will work fine.



This supply is highly useful to power small projects as well as big ones. It will handle 6 and 12 volt FM two-way radios or 24 or 28 volt surplus gear as well as charge batteries. With a 4Ω limiting resistor it even pulls a nice little arc.

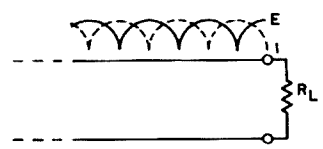
TRANSMISSION LINE SECTIONS

In modern amateur practice the transmission line is usually of the concentric or coaxial type, although it could also be of the parallel conductor type (i.e., shielded or unshielded twinlead and open-wire lead). Most amateurs, if shown a length of coaxial line, could readily suggest the obvious use; namely, interconnecting the antenna and the station equipment. But it would be safe to wager that only a few would be aware that a carefully selected length of transmission line terminated properly can be made to act as a capacitor, an inductor, or even a resonant circuit.



TYPE	DIELECTRIC	VELOCITY FACTOR
COAXIAL	POLYSTYRENE	0.66
COAXIAL	FOAM POLYSTYRENE	0.78–0.80
300 OHM TWIN-LEAD		APPROX. 0.70
75 OHMS TWIN-LEAD		APPROX. 0.80

A transmission line has a characteristic impedance (Z_O) determined chiefly by condutor size and spacing and by the dielectric constant of the insulating material betweer the conductors. If a transmission line is terminated in a load whose impedance is equal to the Z_O of the transmission line, it is said to be flat, or nonresonant. This is the desired condition when using it as a feedline.

However, if the line is terminated in something other than its Z_O, strange things begin to happen. Such mismatch results in reflection of energy from the terminating load and creates standing waves on the line, the interaction of the outgoing and the reflected energy being the cause of the waves. Extreme mismatches occur when the line is terminated in a short circuit or if left open-circuited. Referring to Fig. 1 will give some idea of what occurs. If R_L is much greater than Z_O a voltage maximum results and vice versa. A voltage minimum along the line would mean that the generator would "see" a low impedance if attached at that point. Note that peaks and valleys of either the voltage or current curves are electrically separated by a quarter wavelength.

a) R_L much less than line impedance. Voltage minimum, current maximum at load.

b) R_L much greater than line impedance, voltage maximum, current minimum at load.

Fig. 1. Current and voltage standing waves on a transmission line terminated in a resistive load.

Going on to Fig. 2, consider an open-ended transmission line whose length is an electrical quarter wave. The terminated end is "shorted" by a load whose impedance is infinite and therefore a voltage maximum will exist. A voltage minimum will exist a

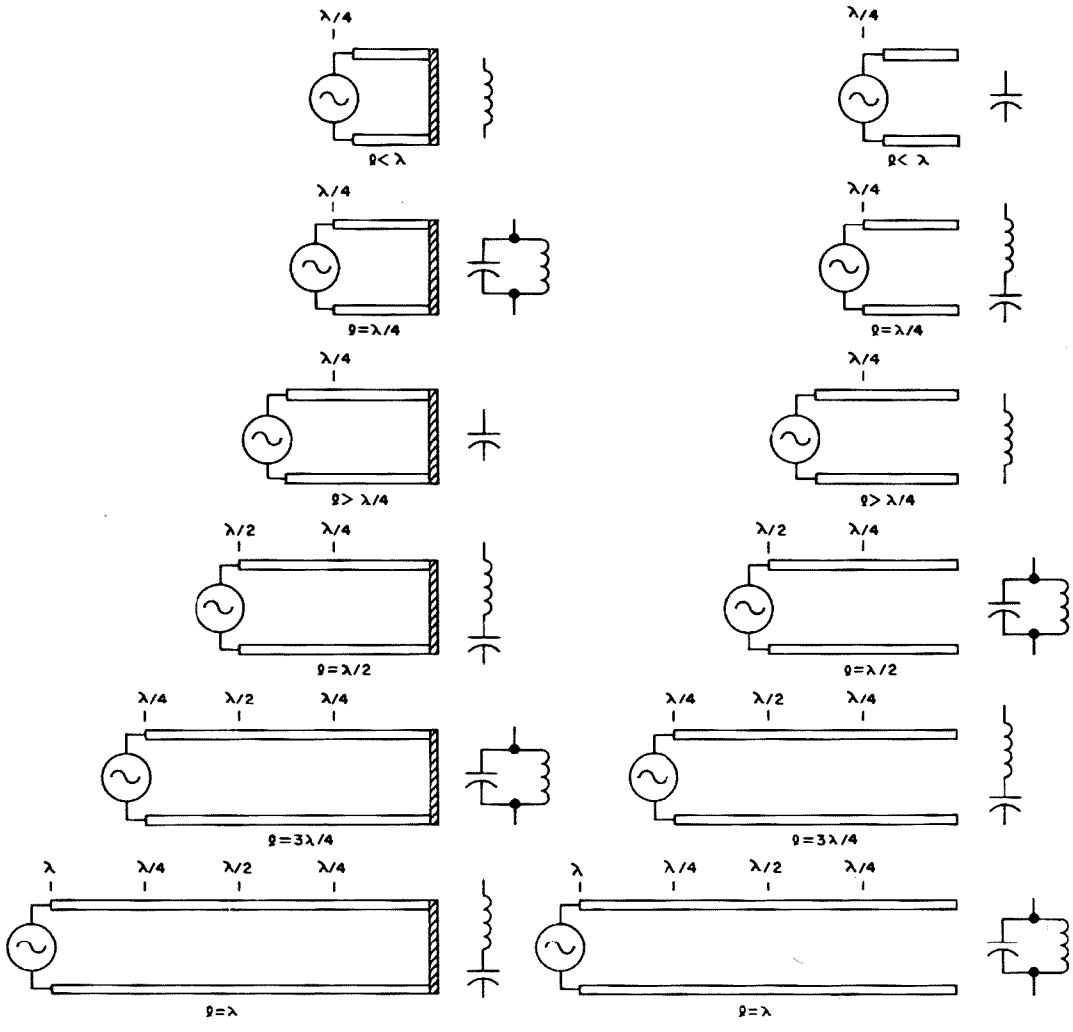


Fig. 2. Impedances experienced by an rf generator for various lengths of transmission line.

quarter wave to the left — which incidentally is where the generator is attached. Remembering that a series-tuned circuit acts like a short circuit at its resonant frequency and that the generator is seeing a very low impedance beause a voltage minimum exists there, it seems logical that the line could be acting as a series-resonant circuit, as indeed it is. Quarter wave and half wave sections of transmission line have many practical uses, as further study of Fig. 2 will indicate.

These sections will be frequency sensitive and will have high Q. When designing transmission line sections, the physical length of

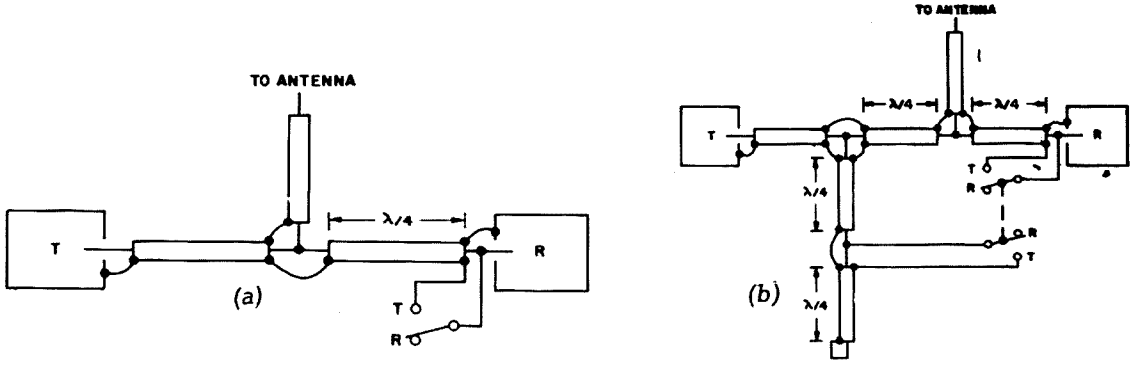

Fig. 3. T/R siwtches for single band operation: a) without transmitter isolation and b) with transmitter isolation.

the section will be found to be less than the free-space wavelength, and is calculated by multiplying the velocity factor times the free-space wavelength. Jim Fisk's Coaxial Transmission Line Handbook[1] contains several tables pertaining to the physical length of coaxial line sections. Some of the standard and not-so-standard tricks with transmission line are touched on in the remainder of this article.

Coax Tr Switch

The switches shown in Fig. 3 utilize quarter wave and half wave sections in the shorted condition to provide receiver isolation during transmit. Dual-band operation is possible on certain harmonically related bands such as the 40 and 15 meter bands if frequency excursions are not too far from the design center frequencies. Such operation is possible because odd multiples of

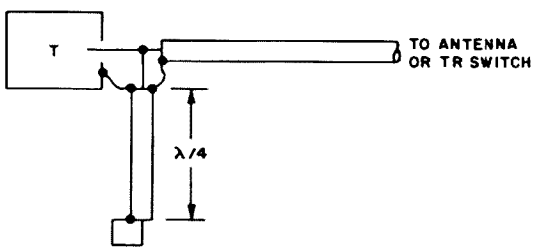

Fig. 4. Harmonic interference trap for transmitter use.

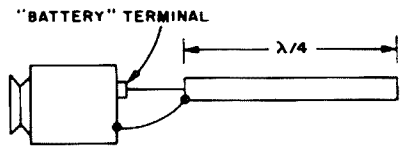
quarter wave sections repeat their characteristics (see Fig. 2). A mechanical switch of some type must be used to short the sections; however, the voltage and current ratings are not too stringent.

I have constructed 50 MHz versions of both Tr switches and found them to work quite well, but no absolute measurements of isolation were made. An attempt to use back-to-back diodes to give automatic shorting of the quarter wave sections on transmit did not give the required isolation – this was to be expected.

Transmitter Harmonic Trap

This type of trap is very effective over a limited frequency range and may be very helpful in eliminating channel 2 TV interference caused by 10m transmitters. Receiver harmonic traps may be constructed from



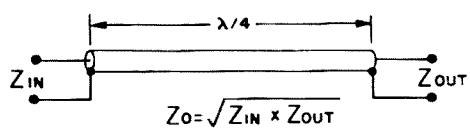


Fig. 5. Alternator filter using open quarter wave coax section.

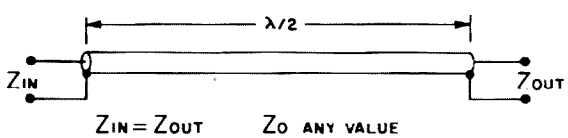
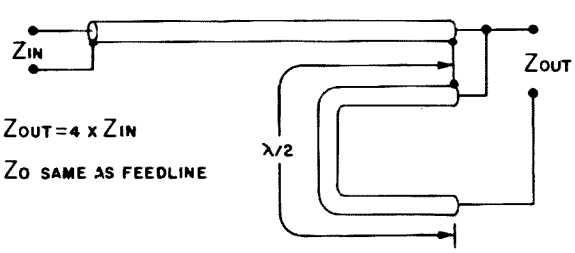
open-ended quarter wave sections and are placed in parallel with the antenna terminals of the receiver[2]. If the transmitter is at 28 MHz, even harmonics (54 MHz, 112 MHz, etc.) are attenuated.



Alternator or Generator Hash Filter

More than one trap may be paralleled to get two- or three-band operation.



Referring to Fig. 6a, the quarter wave transformer can operate both as a stepup and stepdown rf transformer. For example, if Z_{in} is less than Z_O, then Z_{out} will be greater than Z_O. Of course the reverse also holds true. A common application of this

a) Quarter wave matching transformer for balanced or unbalanced transmission lines (unbalanced shown).

b) Half wave matching transformer (1:1 ratio). Applicable to balanced or unbalanced line.

c) Trombone matching transformer (4:1 ratio). Unbalanced to balanced (in direction of impedance stepup) shown.

device is to match the 70Ω impedance of a transmitter to a quarter wave mobile whip whose impedance is about 20Ω. Using the formula given, the Z_0 of the line would be about 50Ω, so a section of 52Ω coax works fine. Although it would not be feasible to delve into the theory of operation of this transformer, its operation is related to what you have seen in Fig. 2 for the open and shorted quarter wave line sections.

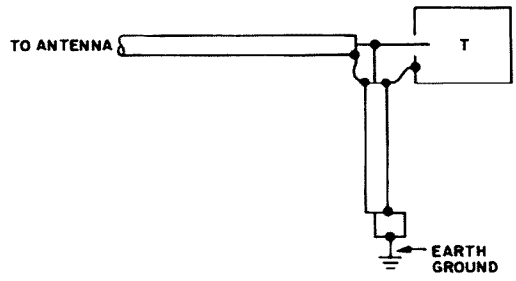

Fig. 7. Lightning protector and static drain.

Lightning Protector and Static Drain

This device can be placed at the transmitter or even at the antenna if a good ground is available. It provides a dc ground but does not ground rf at the frequency it is cut for. Naturally it is inherently a narrowband device, but it does have application with single-band antennas.

In summary, then, these sections are very selective and can provide accurately tuned resonant circuits with only a tape measure and a pair of sidecutters. They make excellent single-band rf transformers. They can be used to construct low-loss rf switches Although nothing was mentioned on the subject of matching stubs, it is possible to use lengths of transmission line to supply capacitive or inductive reactance for the purpose of matching an antenna to a feedline. This review of transmission line sections could at best only hope to skim the surface, since the theory behind these devices would fill a book. It is hoped the reader will pursue this subject further and in greater depth.

RADIO ASTRONOMY for RADIO AMATEURS

The thought of optical astronomy conjures images not only of Mount Wilson and Palomar but also of the many thousands of amateur observers throughout the country. On the other hand, radio astronomy brings to mind visions solely of huge installations such as Arecibo and Jodrell Bank; this is in large part due to the availability of small visual instruments, which makes amateur participation possible, and popular. Such optical observers send in hundreds of reports each month to national societies such as the American Association of Variable Star Observers, and their data prove invaluable to astronomical research.

Predictably, radio astronomy currently has no similar "sky patrol." However, it is possible for hams to initiate such a watch on their own with a reasonable initial outlay using essentially what equipment they presently possess. I intend to show in this brief article what kind of set-up is necessary and what data can be obtained from radio astronomical observation.

One of the primary factors influencing the quality of HF and VHF radio transmissions is the emission of the sun in the region of the electromagnetic spectrum from the ultra-violet through the x-ray domain. Some correlation exists between visually observable sunspots on the one hand, electronically detectable solar radiation in the HF and VHF range, and short-term behavior of the ionosphere on the other. Analysis of either or both of these phenomena can have substantial predictive value for skip conditions. The ham is in an ideal position to gather, analyze, and make use of such data. This is still a wide open field where original research with simple equipment can potentially be of significant scientific value.

A brief word on the history of radio astronomy may suffice. Forty years ago, January of 1923, Karl G. Jansky, a Bell Telephone engineer, detected "a steady hiss type of static of unknown origin." He had discovered the radio emission from the center of our galaxy at a frequency of 20.5 MHz. Five years later Grote Reber, working with a homemade parabolic dish antenna in his backyard started exploring the sky in the VHF region. In 1944 he published the first maps of the radio sky and in the same year detected solar radiation at 10 MHz. G. C. Southworth and J. S. Hey subsequently found solar thermal emission at centimeter and meter wavelengths, respectively. The developments in radio astronomy since the war (the prediction and detection of the interstellar hydrogen line at 1420 MHz, to name one) have been too numerous to recount here; the interested reader is referred to the works listed in the bibliography.

How difficult is it to get started in radio astronomy? Not at all, really. This author has successfully supervised a group of high school students using little more than unsophisticated FM receivers and TV antennas to observe both solar and extra-solar radiation. The advanced amateur radio astrono-

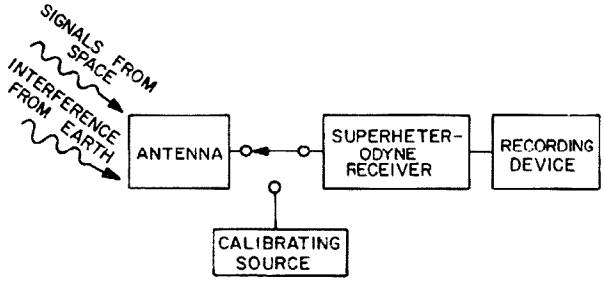

Fig. 1. Block diagram of a radio telescope.

Fig. 2. The 22.2 MHz receiver and Esterline Angus recorder at the Kalbfleisch Field Research Station.

mer may eventually wish to expand his observations to extra-galactic sources which provide a greater challenge due to the generally weaker signals involved. But the sun makes an ideal first target because of its relative strength and discernible effect on radio communication.

A radio telescope consists basically of the items shown in Fig. 1. Initially, the calibrated source can be omitted since measurements will be taken relative to an arbitrary baseline. A desirable receiver will have a very low noise figure and extremely high gain stability (for every gain variation is seen as a change in the recorded noise level). Typically, regulation to 1 part in 40,000 for high voltage and 1 in 3,000 for filament voltage are employed. The recording device for our purposes could be no more than a glorified S meter, but preferably a strip line recorder.

In 1968 I first experimented with the feasibility of a small scale radio observatory at the Kalbfleisch Field Research Station (Huntington NY) of the American Museum of Natural History. Our "shack" consisted of a single channel receiver operating at around 22.2 MHz, an Esterline Angus model AW recorder, and an eight element Yagi (see Figs. 2 and 3). We naturally directed our attention to the sun, being the strongest source of extraterrestrial radio waves with the qualified exception of Jupiter, but that's another story entirely. Using the armstrong method we were able to point the beam at the sun throughout the greater part of the day. (By the way, it gave excellent results on 15 meters.) After a while we were able to identify the various types of solar bursts we had recorded, and recognize their characteristic sound when we heard them again. A detailed description of these emissions can be found in Steinberg and Lequeux. (See bibliography.)

Although virtually any type of antenna may be used initially, the ordinary three element beam (or, of course, larger) is preferred because of its directivity and subsequent gain. The feed line should be adequately shielded and unbroken from antenna to receiver. Any possible sources of attenuation, such as T-R relays and lightning arrestors, should be removed from the line (unless one is monitoring a local lightning storm, in which case an arrestor is a necessity!).

The receiver should be ideally a single conversion superheterodyne with a high S+N/N ratio. A rough way of ascertaining the noisiness of your receiver is first to listen on a clear frequency at midday, using the widest selectivity available, with the antenna first connected, and then with a 50Ω resistor across the receiver input terminals. The drop in noise level should be significant. Repeating the test at three in the morning should yield an almost imperceptible change. This is

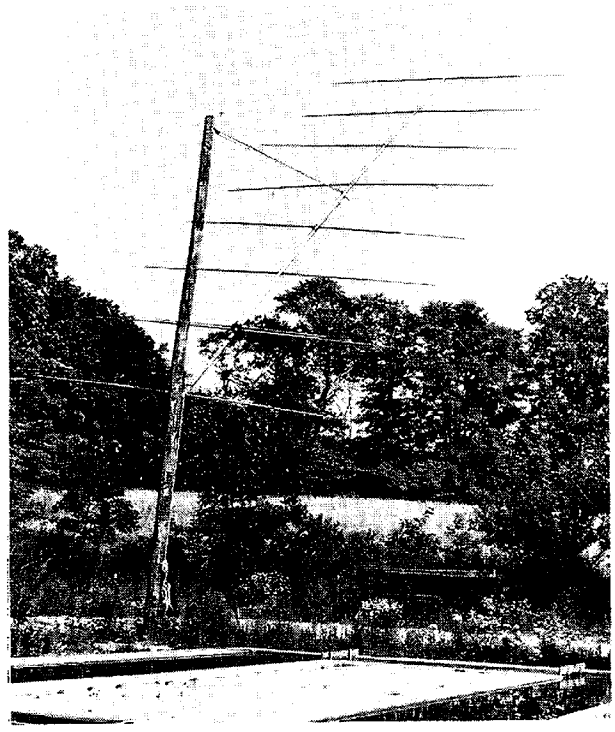

Fig. 3. View of the eight element beam used in the Kalbfleisch system (photographs courtesy the American Museum of Natural History).

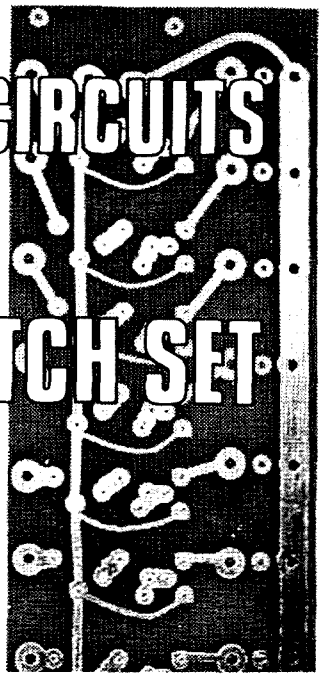
a good sign that the system is both quiet and sensitive enough to make detection of solar emission possible.

Up to this point I have not mentioned what frequencies should be used for observations. The three major considerations here are transparency of the ionosphere to incoming signals of that frequency, freedom from terrestrial interference (both communications and noise), and performance of your system (receiver plus antenna) at that frequency. As a rule the 15 meter band is a good place to start. The Kalbfleisch station has for several years monitored extraterrestrial sources at 21 MHz using only a commercial three element monobander for an antenna.



Choose what appears to be a clear frequency either below or above the ham band. International fixed stations above and aeronautical stations below will make frequency selection a difficult matter. After you have found an open spot, stay tuned to it for several days using the broadest selectivity to ascertain its freedom from potentially interfering stations. Listen carefully and after a while you should begin to recognize noise that sounds not like ordinary QRN. If you are fortunate enough to have once heard an audio recording of a solar flare, you might identify what you are receiving as such. Remember to use broad selectivity – the purpose of this is to allow as much as possible of the signal (which is essentially broad banded) to go through, since power output will be directly proportional to bandwidth. The Kalbfleisch unit uses in its i-f amplifier a crystal filter with a width of 13 kHz.

Now that you are reasonably certain the sun is coming through well, you can consider the matter of recording the output. There are several choices available as to from what stage the signal should be taken. At Kalbfleisch we rectified the audio output of the receiver, and having imparted a characteristic time constant to it (R x C), fed it into the 0–1 mA graphic recorder (Fig. 4). The purpose of the back biasing arrangement is to allow the recorder pen to be positioned so that the full scale of the instrument can be used. The 47,000Ω resistor simply isolates the dc power source from the recorder.

PRINTED CIRCUITS

FAST — EASY with DATAK's

DIRECT ETCH SET

EASY—patterns rub down directly on the copper board and connect with rub-down lines or tapes supplied.
FAST—safe new etchants will etch a 2 oz. copper board in 30 minutes.
ACCURATE—±.002" print tolerance so parts and connectors mate with no errors.

Circuit Made With ER-1

COMPLETE ER-1 SET contains hundreds of dry transfer DIP, flatpack, TO-5, IC, and transistor patterns; 1/16" and 1/32" etch resist tapes; 4 copper clad boards; 1/4 lb. dry etch; tray and instructions. $4.95 ppd.

Clearly, the higher the value of R, the lower the current the recorder will see. We were hard put to find individual paper capacitors to provide the necessary time constant of about five seconds. Electrolytics were avoided since experience has shown that their capacitance varies too much with time and temperature to be useful in serious work, though they are perfectly satisfactory for initial observations.

An alternative to rectifying the audio output is taking the filtered detector voltage from the receiver, which will be in the order of 1/2 volt, pass it through an RC circuit similar to that in Fig. 4 and then feed it directly to a recorder with the requisite sensitivity. During period of observation the receiver avc should be turned off or grounded at the appropriate place, since the R-C combination provides the time constant regulation necessary; the anl, noise blanker and such should also be off.

A graphic recorder is the one piece of equipment needed to complete your observatory. Unfortunately for the prospective radio observer the prices of new units tend to be rather high. A survey of Philadelphia and Washington, D.C. surplus shops reveal a preponderance of recorders designed for 220 volts ac at 50 Hz, which can be bought for less than $80. The effect of running such an instrument on a 60 rather than 50 Hz line is that the chart speed will be slightly higher than normal, just enough as to make time readouts on standard paper difficult. If you are inclined to experiment a little with clockwork, it is possible to build into an ordinary wall clock a device which will send out pulses every so often, say at hour or half hour intervals. This way the time of a particular event can be readily determined. As an alternative to purchasing a recorder, the physics department of a local university can be checked out as a source of a loan of one.

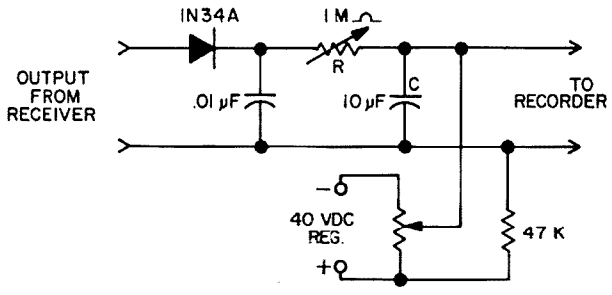

Fig. 4. Detector and back biasing circuit used between the receiver and recroder. The variable resistor R and the capacitor C determine the time constant.

Just to become acquainted with the noise strength profile at the frequency you have chosen, let the recorder run at five to six inches an hour for several days. Because of ionospheric absorption and divergence (see Hanbury Brown and Lovell, p. 16), signal strengths will be greater towards midday. Studying the profile of bursts requires a speed of twelve to twenty inches per hour, but this must not be done indiscriminately, lest you find your paper consumption getting out of hand.

The information you should seek as a result of your observations is what correlation exists between type and intensity of solar outburst and propagation on the amateur bands. Data such as what frequencies, areas and paths are affected are of great interest. I would be pleased to hear personally of the problems and progress the amateur radio astronomer encounters.

I have concentrated here only on the sun, being the most readily observable radio source. If you are so inclined you can find a list of celestial radio emitters in the several books on radio astronomy listed in the bibliography. It will hopefully not be long before optical astronomy associations have their counterparts in radio astronomy. Hams could potentially provide a vast amount of valuable data to the scientific community, and themselves gain an understanding of the still obscure workings of the universe.

A DIRECT READING INDUCTANCE METER... THE "HENRYOMETER"

I know for a fact that many of my friends, as well as myself, have boxes of chokes and coils which are of no use without known values. Most of these inductors, it will be found, are still good and may have applications in projects. Even though the chokes may be aged and dusty, underneath may be a coil that could save you a bit of money on that receiver or linear you are about to build. All you need to save yourself this time and money is a "Henryometer." Unlike bridges, which are slow, and many times inaccurate, or the capacitance method of resonating with a grid-dip meter, the Henryometer reads directly, like an ohmmeter. All it should cost you is a few parts from the junkbox and a little time.

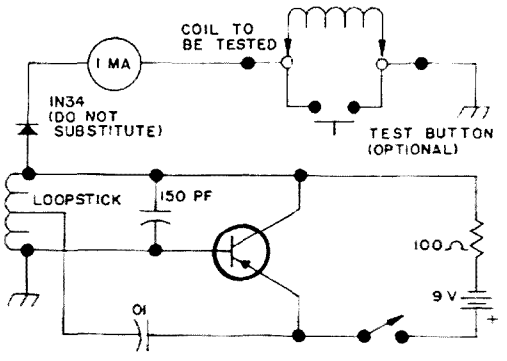

Fig. 1. Circuit of the direct reading inductance meter.

The Henryometer is based on the formula for inductive reactance. This states that the two variables which control reactance are frequency and inductance. Since the Henryometer supplies the frequency, inductance will control reactance. Thus, this is a reactance, or ac ohmmeter. It operates in the same way as a dc ohmmeter except that an oscillator replaces the battery, for an ac current; and a diode on the meter changes it back to dc to register on the direct current milliammeter.

You will find this meter very easy to build and simple to operate. Most any PNP transistor will work in it, but the diode *must* be a 1N34. The case can be made very small, for all that need be contained is a battery, meter, potentiometer, and small circuit board. To test a coil, connect it across the terminals, push the test button (or connect the leads as with an ohmmeter), adjust the control for zero, or one mA, let up on the test button, and read the value indicated. You may calibrate it with known values. It should read accurately from .25 to 10 millihenries. You might wish to add ranges by adding a selector for meter shunts. One important precaution is to use leads as short as possible to keep added inductance as low as possible.

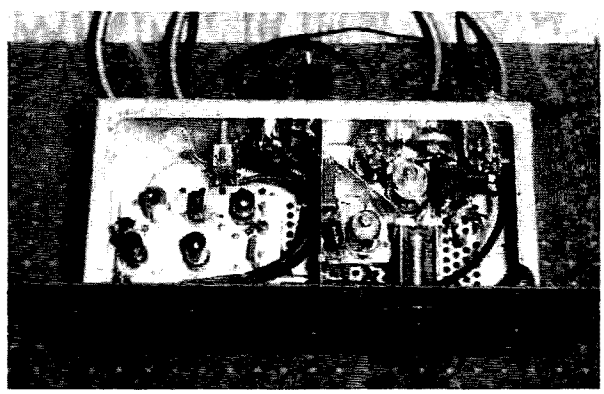
TRANSVERTER FOR 20 METERS



Paul L. Schmidt W9IDP
214 North Washington
Bloomfield IN 47424

Expand the coverage of your single or dual band transceiver with a unit that features convenient high-level mixing.

This is primarily for those having single-band or two-band transceivers having 75 or 80 meter capabilities but with no provision for 20 meter operation. This describes an outboard 20m transverter which is hooked into the transceiver antenna line like a linear amplifier with its receiving and transmitting functions controlled by the transceiver working on 75m.

The transverter uses the same crystal for both receiving and transmitting conversion. This way the transceiver you are using "thinks" it's on 75 while it is actually on 20m. Aside from the added 20m coverage, no modification of your present transceiver is made; thus, the resale price is unaffected.

Whenever I am exposed to a "how to" article, there is always something not just

exactly right about the other author's design. Therefore, the reader is here encouraged to receive my ideas in the same light, to make his own improvements or modifications to what is described.

Figure 1 gives the functions of the transverter stages. I use a 6.025 MHz

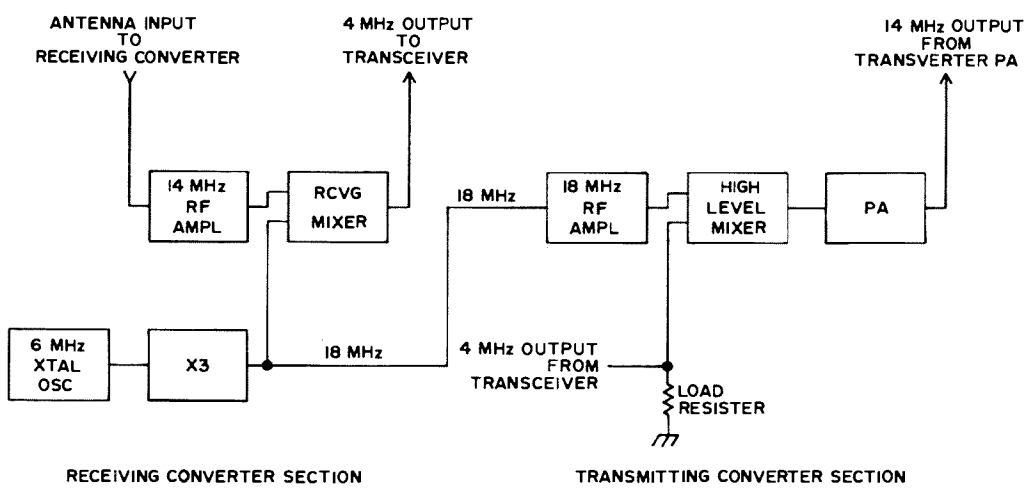


Fig. 1. Functions of transverter stages.

FREE HANDBOOK

1200 PAGES!

Where else can you get an amateur radio handbook for free? That's right, you get about 1200 pages of articles in 73 every year and the magazine is designed so that each and every article is on separate pages – and 73 is the only magazine that does this – with no flipping to the back of the magazine for a parts list or anything. Every page of the magazine is numbered with the regular numbers plus special yearly handbook page numbers – all so you can, if you like, take apart your issues of 73 and put them together by subject into a giant handbook at the end of the year. No other magazine has anything like this available.

ACTIVE EDITORS

Only one ham magazine of the four has editors that are active and on the air – and have been for years. 73 has its own repeater going – the only ham magazine staff that has done this. 73 has its own mountain top laboratory for VHF – the only ham magazine with one. 73 is active on slow scan television – the only magazine to do this. 73 goes on DXpeditions – the only ham magazine to do this. 73 runs DX tours – the only ham mag to do this. And so it goes.

And what difference does all this make? Perhaps you've noticed that 73 is more involved with the hobby – 73 not only reports the most interesting news, sometimes it helps to make the news. It helps 73 to be more fun to read, to attract better authors for articles, to bring you more valuable information on the newest of ham products.

Which ham magazine was the first to report on the first commercially made two meter synthesizer? 73 of course. And which got the first new units made by Genave? And which got the first Clegg units? The first International Signal units? The first Drake FM units? The first Tempo units? And so on – being active and on the air helps make 73 more interesting and valuable, doesn't it?

73 NEWS PAGES

You'll enjoy the monthly news reports on what is going on in the hobby – new products – political happenings – news of DX – RTTY news – Slow Scan news – VHF news – FCC news, etc. 73 is the ONLY ham magazine to cover the news of amateur radio in this easy to read manner. Keep really up to date with the 73 newspages.

73 MAGAZINE PETERBOROUGH NH 03458

If you prefer not to shred your copy of 73 there is no real reason why you should not put the subscription information on a separate piece of paper, on the margin of a hundred dollar bill, or whatever turns you on.

Regular subscriptions ordinarily start with the next published issue of 73 – the November issue, in this case. Gift subscriptions marked for Christmas will start with the Giant January issue since that is the one that should arrive right around Christmastime. If you want otherwise just indicate same on the order.

The regular subscription rate for 73 is $6 for one year $11 for two years, $15 for three years in North America and $1 extra per year for foreign subscriptions. This special book premium offer is valid world wide at $6 for one year until December 31, 1972.

The recent serious rise in postal rates will be forcing 73 to increase the subscription rate soon – don't say you weren't warned.

Did you enjoy the article in August on the DXpedition to Navassa? This is one of the reasons that 73 is different – it is involved. The editors get out there and operate, go on DXpeditions, organize them even – organize ham tours – set up repeaters – work in the contests – work lots of DX – are actually on slow scan – on RTTY – it makes the magazine come alive. When the editors write about something you know that they have the background to bring you the inside scoop. If you are the type of person who fights progress – opposes change, you are going to find 73 getting your back up, for 73 is in there first with the new things.

Amateur Radio
is more fun
When you read 73

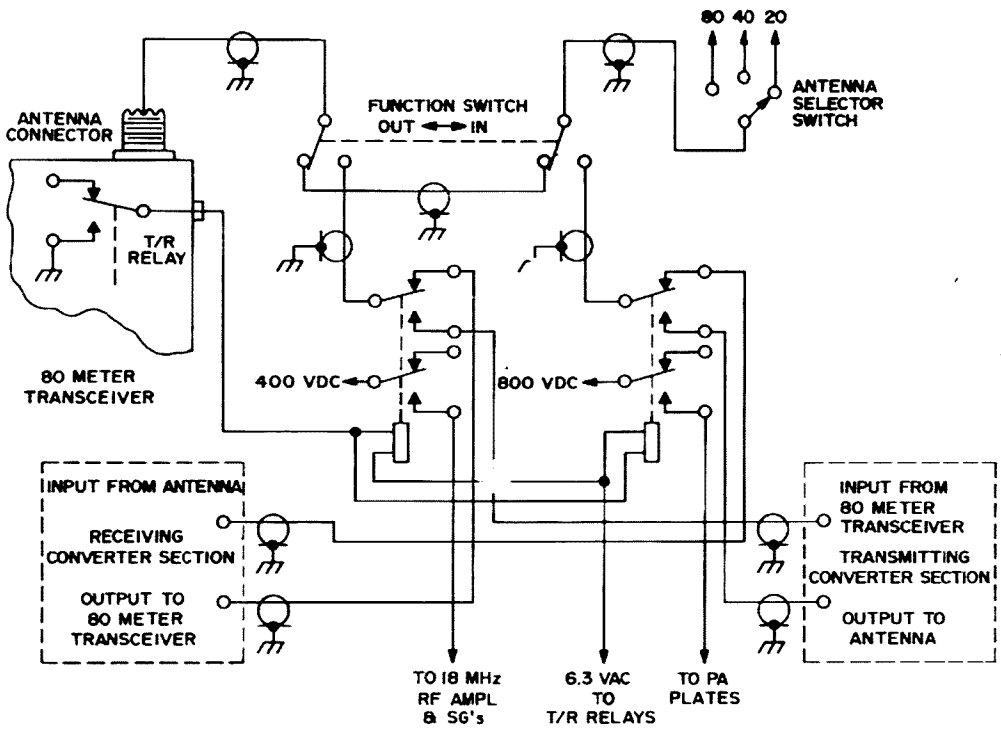

Fig. 2. Transverter control circuitry.

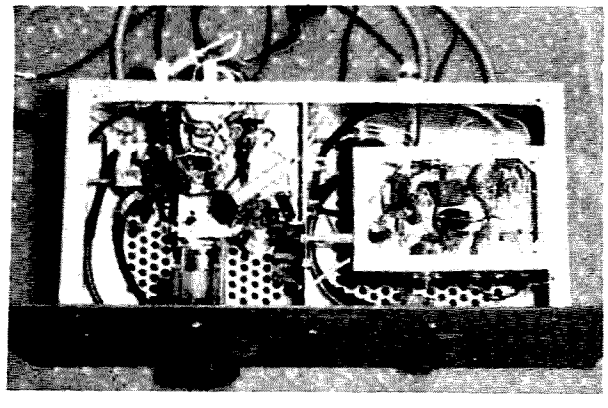
crystal oscillator and triple to 18.075 MHz. Then the amplified incoming 14 MHz signal heterodynes in the mixer with this to produce the 4 MHz output for the transceiver's receiver. The receiving converter and crystal oscillator–tripler remain on during the transmit mode, but during transmit, an additional 18 MHz rf amplifier turns on to provide more 18 MHz power for a high-level transmitting mixer.



And in the transmit mode, your transceiver's 4 MHz output goes into a 50Ω load in parallel with the input of the high-level mixer, the output of which drives the 14 MHz power amplifier.

My crystal oscillator frequency of 6.025 MHz was chosen because the crystal happened to be on hand. Its third harmonic, 18.075 MHz, mixes with 4.000 MHz to give 14.075 MHz for CW operation, and 3.800 MHz lower sideband (the low end of the dial of my WRL Duo-Bander 84) produces 14.275 MHz upper sideband. Note that the required sideband inversion is accomplished in the conversion process

A happier choice of crystal frequency might have been 6.067 MHz, whose third harmonic, 18.200, would give full phone band coverage and a little bit more, going from 14.200 to 14.400 MHz.

Because your transceiver dial isn't calibrated for the 20m band, and since the aim of this exercise is to keep your transceiver unmodified, it becomes necessary to make a conversion chart in order to know your operating frequency. A suggested design is shown in Fig. 6.

To have the transverter in the transceiver antenna circuit at all times, like a linear amplifier, it must be switched from "out" (straight through) to "in" (transverting to 20 meters) by means of a substantial double-pole-double-throw wafer switch. Two DPDT relays perform the transmit-receive operation from your trans-

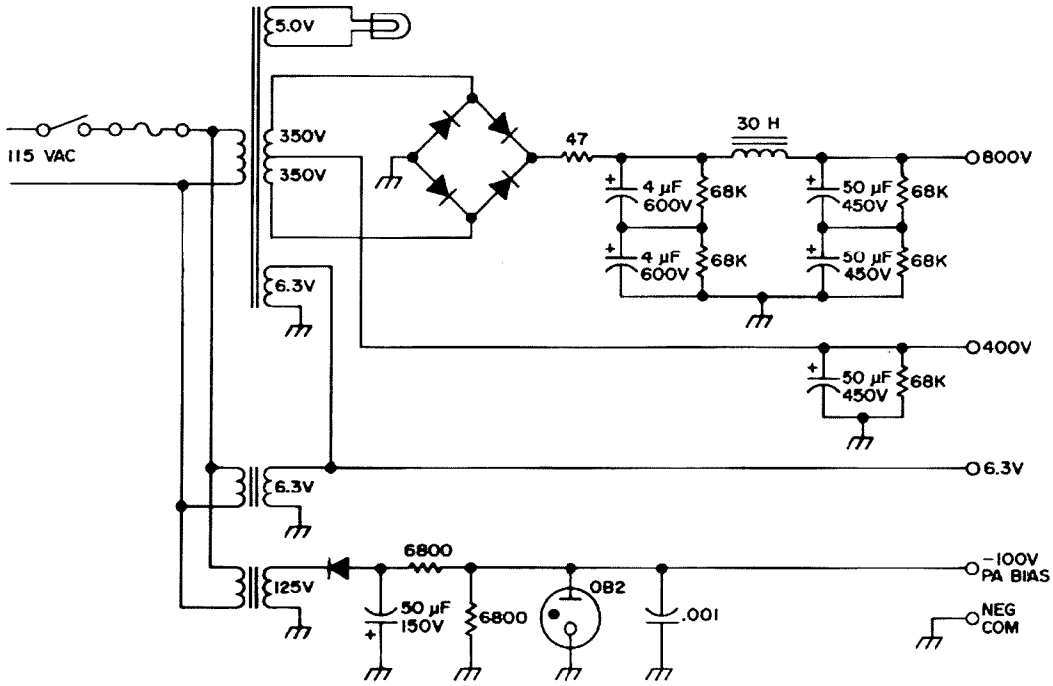


Fig. 3. Transverter power supply.

ceiver's TR relay. Control circuitry for all this is shown in Fig. 2.

Now that the functions have been roughed in, the construction steps should follow in some logical order. Plan your layout for ease of maintenance and repair if possible. The one I built requires removal and replacement of nine screws just to change a pilot bulb.

You might like to complete the receiving converter and power supply first. Then you can listen to 20m while completing the transverter. Don't forget to unplug the microphone from your transceiver during the construction phase while listening to 20m; otherwise, you might forget and transmit through the receiving converter (not recommended). A grid dipper is a must for pruning and tuning. If you don't own one, better borrow one.

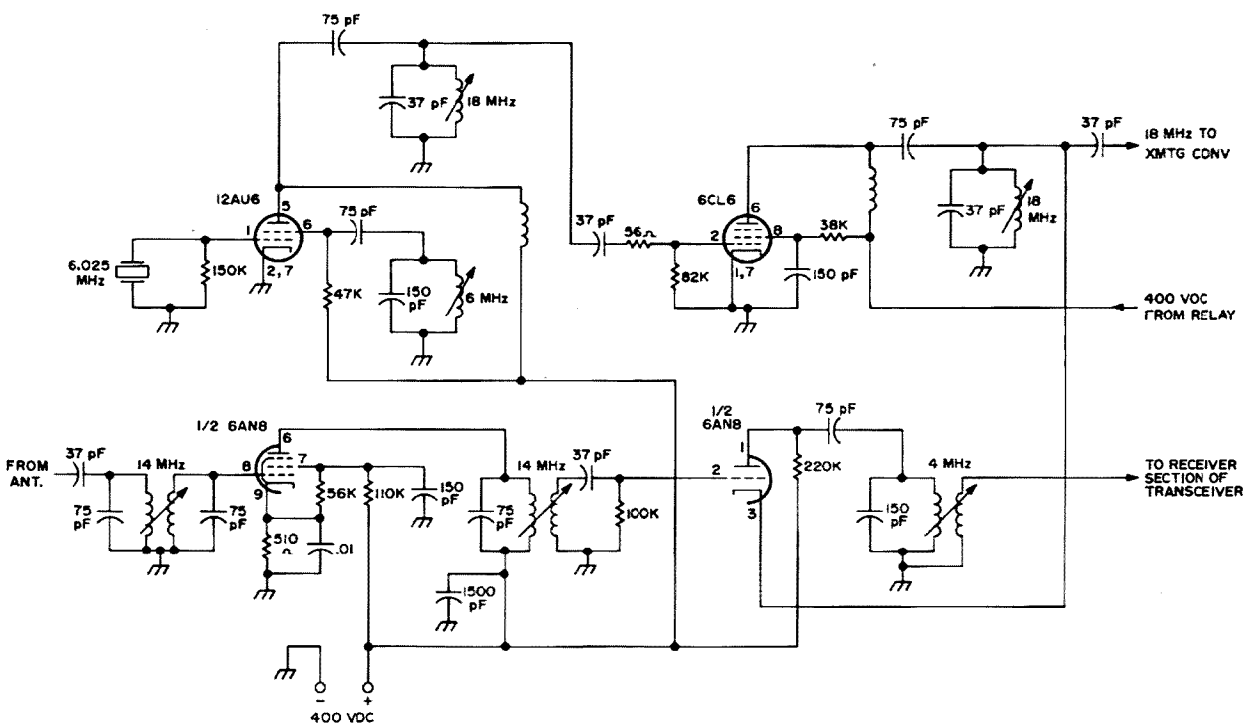

Fig. 4. Receiving converter.

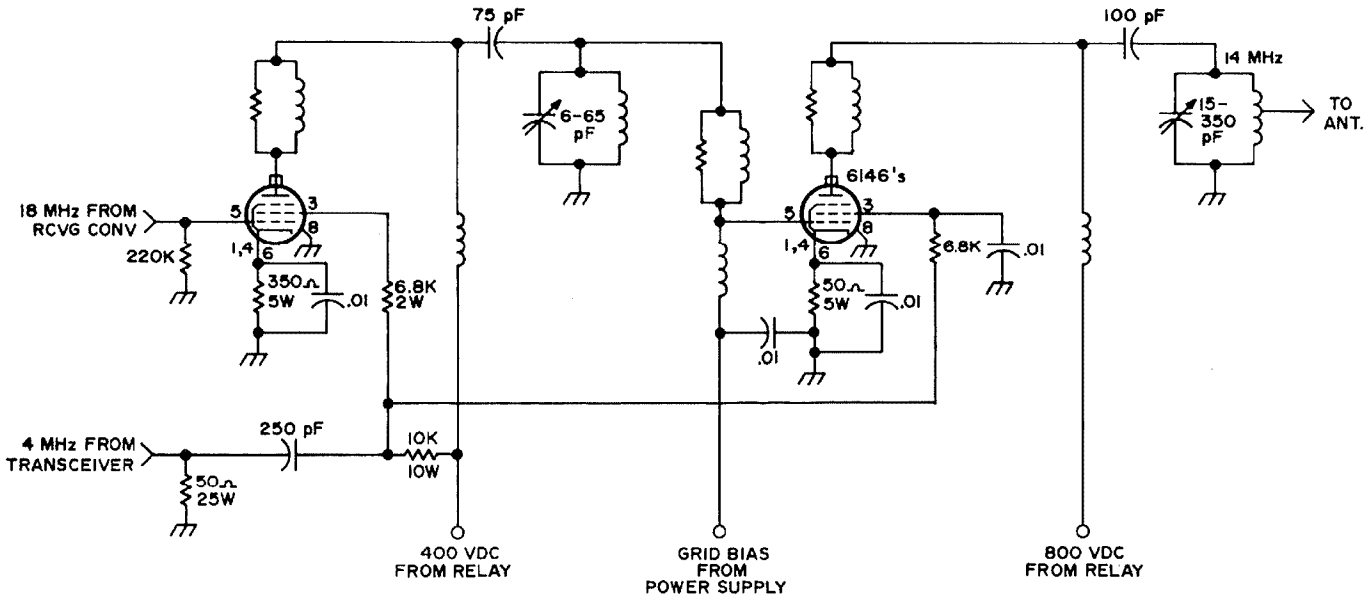

Fig. 5. Transmitting converter.

Figure 3 shows the power supply. Because my available control relays were 6V ac types, I decided to run a 6V line between power supply and transverter (as opposed to the usual 12V line). This practice can spell trouble unless the filament cable and the common return bus are of generous wire size. With relays energized and filaments lighted, the current averages 5A. Just half an ohm of interconnecting cable resistance can drop the filament voltage from 6.3 down to 4.6V, with resulting marginal operation.

Figures 4 and 5 complete the whole nine yards. Construction details are left to the builder's good judgment. From the experience gained in constructing this little gem, I would say that the most vulnerable part is the rf power amplifier following the high-level mixer. The 6146s are prone to parasitic oscillations. With 800V on the plates these tubes can disintegrate in short order. If my good friend Lew (W9YEA) had not sustained my needs by furnishing extra 6146s, I never would have been able to complete the project.

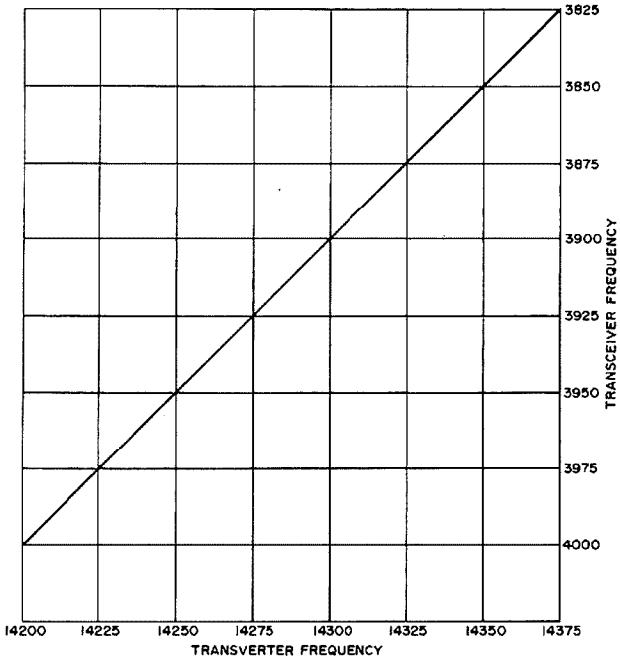

Fig. 6. Frequency conversion chart.

On December 23 my transverter was completed. On Christmas morning I worked VK3VG. On the 28th I contacted KZ5AB, and on the 29th, KH6AX. This is quite good considering the antenna, a dipole 25 ft up at its highest point – a dipole installed with the assistance of a loving and patient wife at night in a snowstorm.

You may wish to vary the circuit elements to suit the requirement, such as transverting from 20m to 75m, etc. One unique feature of this transverter is the high-level transmitting mixer, which works better than anticipated. Another bonus is the complete lack of birdies or images from the receiving converter. In fact, it is the first such converter I've built which exhibited such purity of output.

A PRIMER ON LEDS

The surplus market is flooded with light emitting diodes (LEDs). They have some great characteristics and are easy to use.

What are they? They are diodes, they rectify just like any other diode but their atomic structure is such that when the electrons jump from one energy band to another they give off light. This is cold light and is intended to be seen only at the source, it is not for reading.

What good are they? Well, they withstand 1500gs vibration, they will last over a million hours without loss of intensity, they operate on low voltage dc, they come on in 35 nanoseconds, they can interface with any logic circuitry and be pulsed or driven steady state.

How do you use them? They operate on as little as two volts. The critical factor is the forward current. You must limit this forward current. This is done by putting a resistor in series with the diode. This resistor is calculated using Ohm's law:

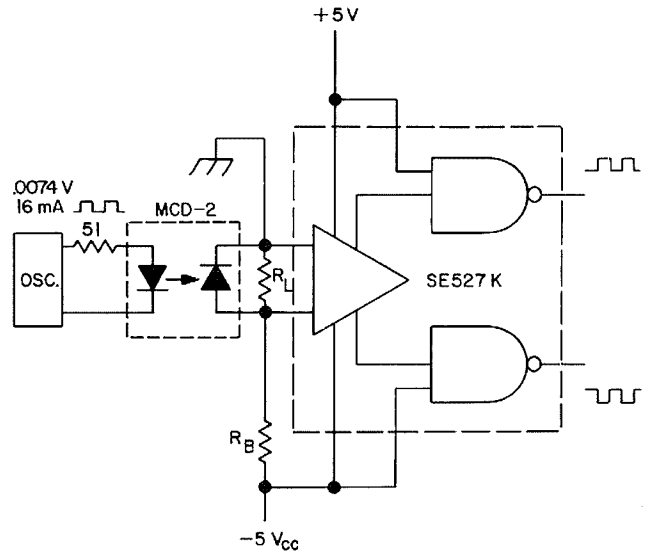
$$R = E/I = \frac{\text{Voltage you want to use}}{\text{Current limit of the diode}}$$

A typical LED burns at about 15 mA; the more current the brighter it burns; this is a straight linear relationship. Some LEDs take 1 Ampere – if you use a heat sink.

The LED like any diode has a cathode (where you connect the positive lead) and an anode, the negative side. You take your ohmmeter and measure the forward and reverse resistance of the LED. When you find the connection with the lowest resistance that is the way you want to connect the LED in your circuit – in the forward direction. You can't hurt it with an ohmmeter.

There are many sizes and shaped of LED but they resolve into two distinct types: those with plastic lenses; and those with a flat face. The lens type is for viewing at a distance and directly in front of the display; and the flat face can be seen at the side more easily but not as brightly.

The first outgrowth of the LED was the opto-isolator. This is a LED and a light sensitive diode in combination. There are also LED-transistor and LED-SCRs. All of these come in a little 1/2 inch long package and they are used for isolating one circuit from another. This eliminates ground loops, transient spikes, and random noise. The difference in these three packages is the transfer ratio. The LED-silicon diode pair has a transfer ratio of 0.15%, for instance, if you put a 16 mA pulse to the LED you get a 24 mA pulse out. If you shunt the output with 42K ohms you have 1 volt to play with. The LED-transistor isolators have a transfer ratio that varies depending on the connection and biasing of the transistor but to get in the ballpark figure one to one transfer



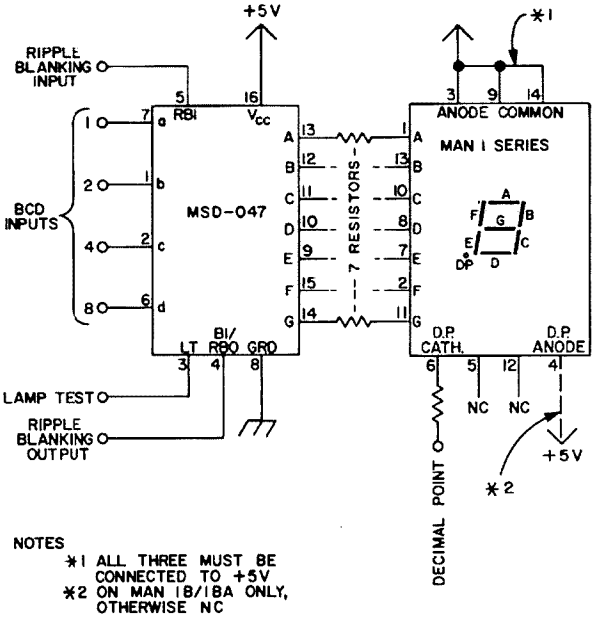


Fig. 1. Experimental implementation of MCD-2 for digital data transfer.

ratio. For instance 15 mA in gives 15 mA out. Why use diodes when transistors are so much better? The diodes are faster and they can transfer logic information.

The LED-SCR is a typical SCR and does anything another SCR can do like acting as a relay or switch except that it is triggered on by the light from the LED. This isolates it electrically from the input circuit.

The diagram shown in Fig. 1 shows a diode opto-isolator transferring a 1 MHz square wave from one circuit to another. In computer circuitry which is very sensitive to transients, this is a great thing. The load resistor RL was one K ohms and RB was the pull-down bias resistor necessary to operate away from the click point of the IC.

NOTES
*1 ALL THREE MUST BE CONNECTED TO +5V
*2 ON MAN 1B/1BA ONLY, OTHERWISE NC

Fig. 2. TTL decoder driver to MAN 1 series.

The next big step in LED complexity is the seven segment numerical display. I only mention this because so many are advertised in the surplus market. If you have one of these you need a decoder-driver that converts BDC information to the proper logic to activate the segments. They usually run on 5 volts and like the single LEDs, the segments must be current limited. Figure 2 shows a typical circuit. If this interests you, write to: *Monsanto, 10131 Bubb Road, Cupertino CA 95014* for their Product Directory and the proper application memos.

FORTY METER FET PREAMPLIFIER

Here is a simple experiment used to familiarize yourself with FET circuitry. Described is a simple forty meter pre-amp which can be used to soup up a transistor shortwave receiver or add sensitivity to an inexpensive 80 or 40 meter receiver.

On several vacation trips I used 60 feet of wire wound on a dowel 3/8 in. in diameter, and then clamped to the car window. Without the pre-amp no signals could be heard even though a loading coil was tried, and several antenna tuning coils. Running coax back to the transmitter in the trunk and installing an antenna relay and control wires, converted me to this simple separate antenna installation with the pre-amp. No measurements were made on the gain, but it makes the difference between no signals and S9 results.

Bottom view of Pre-amp showing input and output coils and FET socket on the back.

Theory

Since this circuit was used just for the forty meter amateur bands, no attempt was made to use variable tuning condensers. The unit was peaked up by adjusting the slug tuning and left untouched.

The RCA FET used in this circuit is the 3N128. It is a high impedance device and is much like a vacuum tube in that it does not load down the coils like a transistor. In this circuit the antenna was attached to the top of the input coil through a 10 pF condenser because a random hunk of antenna wire was used. If the antenna had been a coax fed arrangement, several turns of wire could have been wrapped on the bottom of the coil for coupling. The output of the pre-amp is taken from five turns of number 23 wire into RG174 small coax to get the amplified signal over to the receiver.

The unit was built in an LMB box type 000, 3¼ x 2 1/8 x 1 5/8 in. The slug coils were 24 turns of number 28 wound on J.W. Miller ceramic 3/8 diameter forms, type

4400 or equivalent. These slugs are painted red and cover the 1.0 to 20 MHz range. The coils were mounted in the box as far from each other as possible. Normally there should be a shield between the coils to prevent oscillation, but the circuit was stable and no shield was necessary. If variable tuning condensers were used, the extra mass might suggest a shield because of more radiation in the area between the coils.

There are many stories about being careful when handling FET's, and I do not doubt them. No trouble was had with this unit. The case was held with the left hand, and the snippers held with the other, while cutting off the leads just below the shunt on the leads. Grabbing the shunt while still holding the case, it was slipped off and the leads formed to go into a transistor socket. The book says to use plastic tweezers and not to touch the FET because static charges from snippers might cause damage. Needless to say, you should remove the FET while soldering on the chassis. Wire it all up before putting the FET into place, and then push it in the socket with the power off, and I am sure you will have no trouble.

When the unit is finished, hook up everything and peak the slugs for maximum gain into the receiver. Generally the CW or phone portion of the band can be tuned without readjusting the slugs for any particular antenna. No attempt was made to try other bands. If you wind coils and dip them with a grid-dipper, there should be no problem.

LIQUID PLASTIC WATERPROOFING

Strange as it may seem, the weatherproofing of a coaxial cable splice becomes a difficult problem especially when the splice is to be buried underground. Ordinary plastic electrical tape, over a length of time underground, will allow seepage of water between the layers.

We recently came across a system that has worked very well and that is the use of "Clear Cast" to encapsulate splices. "Clear Cast" is the trade name for a liquid plastic that turns very hard when a proper catalyst is added and allowed to "cure." In its original application, Clear Cast is used for hobby projects such as molding, etc.

In using Clear Cast for sealing coax splices, a cardboard tube ½ in. larger than the coax is placed over the splice. The end of a small balloon is placed over the coax and stretched over the end of the cardboard tube. Of course the splice is opened to put these items in place. The coax is then suspended in a vertical position with the balloon "seal" downward. Clear Cast is then poured in the cardboard tube so as to surround the splice. The hardening catalyst must be added to the Clear Cast before pouring. Correct amounts of hardener or

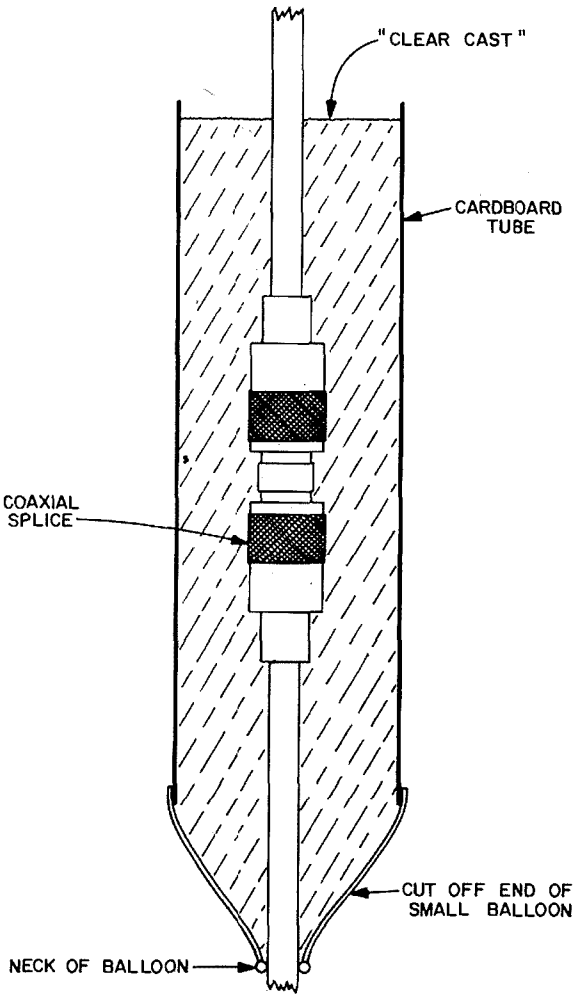

Fig. 1. Coaxial splice waterproofing.

catalyst is prescribed on the container that the Clear Cast comes in. During the hardening process, a fair amount of heat is generated due to the chemical reaction. Approximately six to seven hours are required for complete hardening. Strange as it may seem, the smaller amounts of Clear Cast require longer times to "cure." The larger casts generate more heat and apparently cure faster. Once hardened, the cardboard tube and balloon can be removed leaving the sealed coaxial splice (see Fig. 1).

Clear Cast also works well as a mechanical stabilizer for vfo and other oscillator coil assemblies. A small plastic box, just larger than the coil to be encapsulated, is used as a mold. The coil can be suspended by strings (or whatever means you desire) to a central position in the plastic box. The Clear Cast is poured and allowed to harden. The Clear Cast holds the coil extremely rigid eliminating much mechanical vibration and partially insulates the coil from temperature change. The Clear Cast form can be drilled and tapped to securely mount the coil to a chassis (see Fig. 2).

A third application for this liquid plastic is to encapsulate, insulate and support the vertical element of a ground plane antenna. Again the balloon technique is used to seal in the plastic while in a liquid state. Prior to encapsulating, the coax center conductor is attached to the vertical element and the shield braid is soldered to the copper tubing (see Fig. 3). At this point also, the ground radials should be soldered to the copper tube. The balloon seal is stretched into place and the Clear Cast poured in the top. The plastic hardens and seals the coax and vertical element in place (weatherproof) and insulates it from the copper radial support. The entire assembly is mounted by the use of stainless steel straps to the mast.

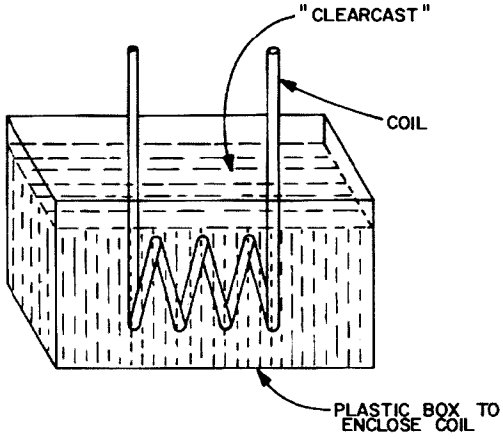

Fig. 2. VFO coil stabilization.

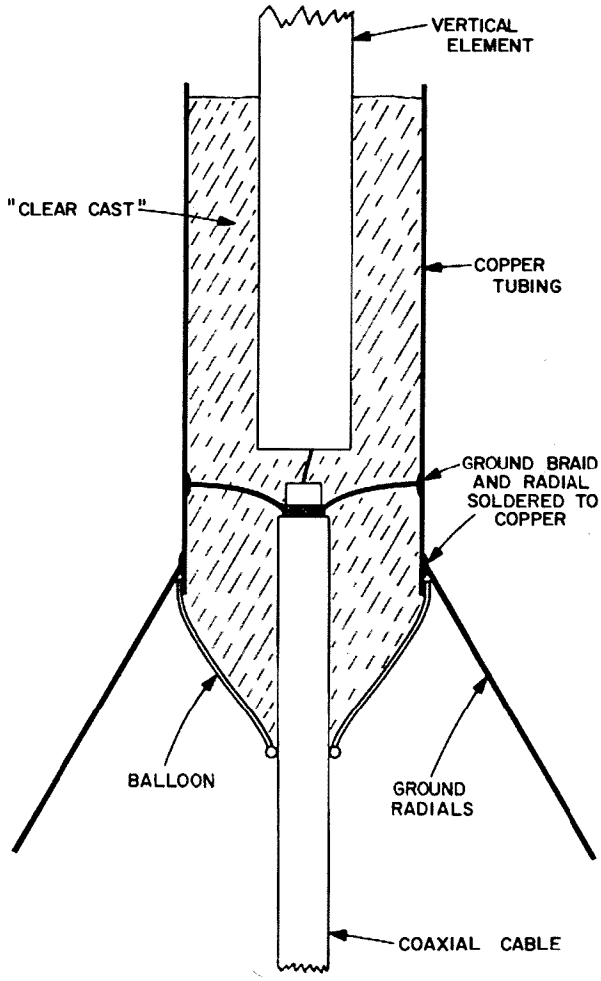

Fig. 3. Ground plane vertical insulation.

If you are using a gamma match type of beam, it might be possible to encapsulate the gamma capacitor to protect it from weather. Of course if you encapsulate the entire capacitor, plates and all, you would have to experiment with the dielectric effect of the Clear Cast when poured between the capacitor plates. Another possibility is to form a "cavity" in the Clear Cast so the capacitor would be variable yet protected.

No doubt once you have experimented with this liquid plastic you will come up with many more applications.

. . .W2AOO

IMPROVED CIRCUITRY FOR KTI CW FILTER

A recent article (*Ham Radio*, August, 1970), described the use of the KTI – Kinetic Technology Inc., 3393 De La Cruz Boulevard, Santa Clara, California 95051 – integrated circuit active filter as a selective audio filter for CW reception. The suggested circuit diagram is shown in Fig. 1. The author constructed this circuit and found it to be a very selective filter, but with certain reservations. At high Q or narrow bandwidth the received signal was difficult to control; the gain of the filter varied inversely with bandwidth, requiring constant readjustment of the receiver gain control.

I discussed this problem with Mr. Fred Glynn, Western Regional Sales Manager for KTI, and he suggested the circuit shown in Fig. 2. He also suggested that I use their Model FX-60 active filter (Amateur class FS-60, $4.95). This circuit works fine and is a pleasure to use. Now the filter has unity gain regardless of bandwidth, i.e., once a

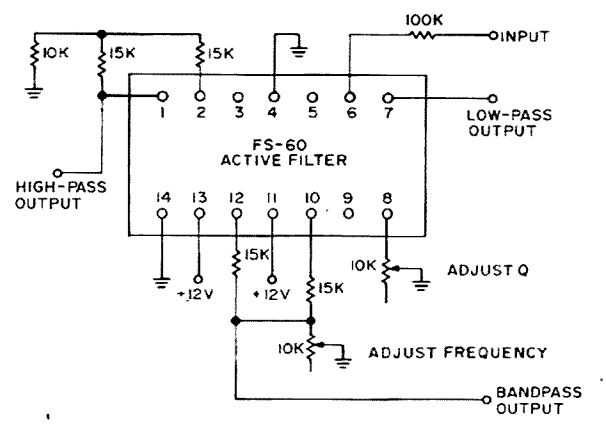

Fig. 1. Original active filter circuit using the FS-60 as it appeared in Ham Radio Magazine.

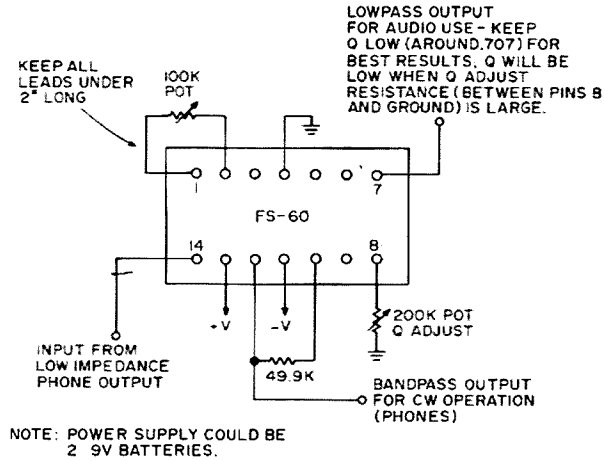

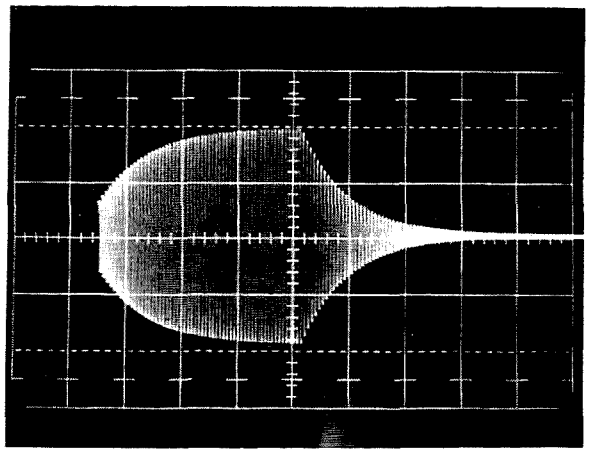

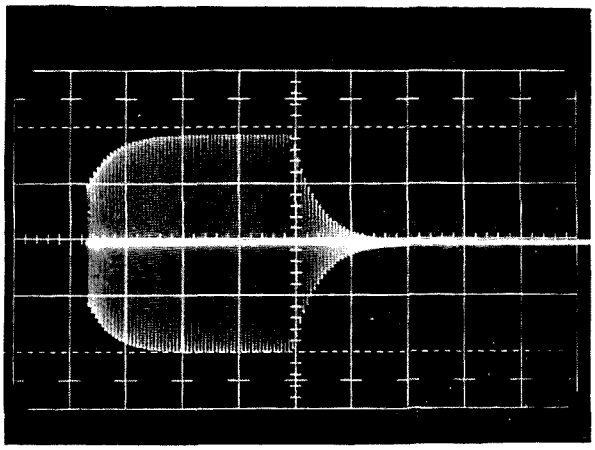

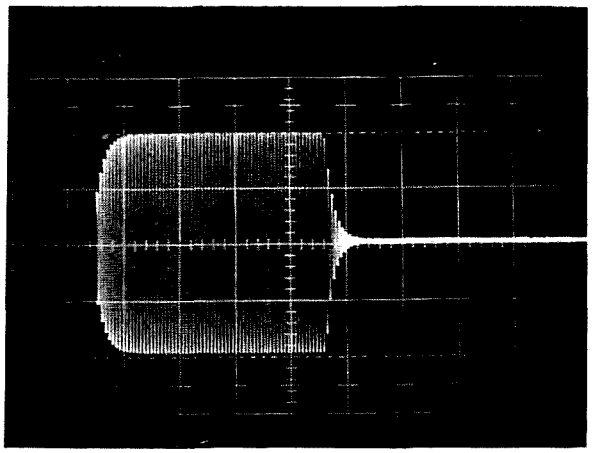

Fig. 2. Modified active filter circuit.

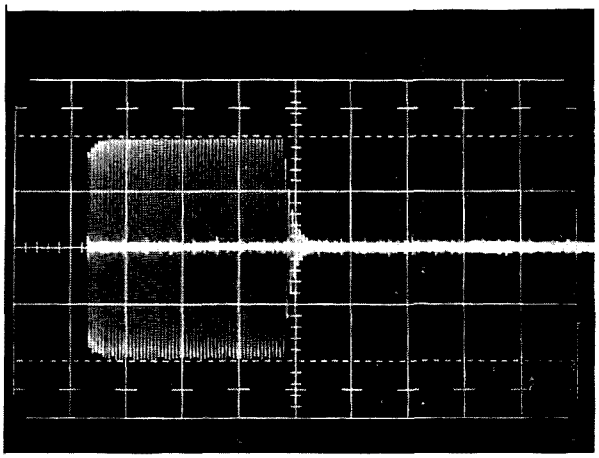

3 dB bandwidth 30 Hz. fo = 800 Hz

3 dB bandwidth 60 Hz. fo = 800 Hz

3 dB bandwidth 100 Hz. fo = 800 Hz

3 dB bandwidth 200 Hz. fo = 800 Hz

Keyed signal characteristics as function of filter bandwidth, horizontal scale 20 msec/cm.

signal is peaked, QRM can be eliminated by means of the Q control. On 80 meters, increasing the Q eliminates most of the background QRN.

One of the inherent problems associated with a selective filter used with a keyed signal is the effect of filter bandwidth on the "sound" or "crispness" of this signal. As the bandwidth becomes very narrow, the filter requires more time to reach equilibrium. As a result, at narrow bandwidths the received CW signal will become distorted as shown in the photographs.

It can be seen that at 30 Hz bandwidth a 70 msec keyed signal takes nearly 70 msec to reach full amplitude and to decay to zero. This signal would not sound too good at a high CW word rate. As the bandwidth increases, the filter output waveform closely approximates the input wave form.

I have used this filter in conjunction with a Hammarlund SP-600 receiver. I can obtain as good or better selectivity and intelligibility with this audio filter and an i-f bandwidth of 13 kHz as I can without the filter and an i-f bandwidth of 200 Hz (excluding single signal effects).

In addition to selectivity, this filter provides the operator with a separate tuning control within the audio bandwidth. Signals can be selected, peaked and interference eliminated without adjustment of the receiver frequency control or bfo. I believe that the CW operator will find this filter a useful adjunct to his receiving equipment.

A TRANSISTORIZED VFO

A perfect project for the newly liberated novice. The circuit is assembled on a printed circuit board for ease in construction.

The problems encountered in the design of a variable oscillator for use in amateur transmitter frequency control are manifold. The circuit must be stable electrically and the mechanical design must be such that the oscillator frequency-determining components are mounted in a rigid fashion. The design to be presented satisfies both requirements and utilizes a rather simple but effective mechanical layout.

In addition to electrical and mechanical considerations, thermal transients are responsible for much of the short term frequency variation encountered in normal operation. The use of transistors and a well mounted toroidal inductor in the tuned circuit does much to eliminate these short term frequency changes.

Circuit Description

The oscillator is the familiar Clapp circuit so often used in amateur vfo applications. It is different from most in that the oscillator is amplitude limited resulting in a low and constant level of oscillation. Q2 is an emitter follower and isolates the oscillator stage from Q3 and the output amplifiers. Q3 is a dc amplifier that supplies bias to the oscillator transistor; an increase in the level of oscillation drives Q3 further into conduction which in turn lowers the base bias on Q1 stabilizing the level of oscillation at a constant value. This results in true class A operation for Q1, a condition which is seldom met in a fixed bias oscillator. It will be noted that the output of the oscillator stage is further isolated from the rest of the circuitry by coupling off the collector of Q1 rather than from the tuned circuit as is usually done. This results in extremely good isolation between the frequency determining elements and the rest of the vfo.

Q4 and Q5 are straightforward amplifiers to raise the output of the oscillator to a usable level. With a nine volt battery the output at the collector of Q5 was more than adequate to drive my home built vacuum tube transmitter which contains an untuned buffer amplifier between the vfo and frequency multiplier chain.

The oscillator coil, L1, is wound on a 1/2" toroid core and the rest of the tuned circuit consists of a variable tuning capacitor shunted by a silver mica padder and two silver mica capacitors in the feedback loop.

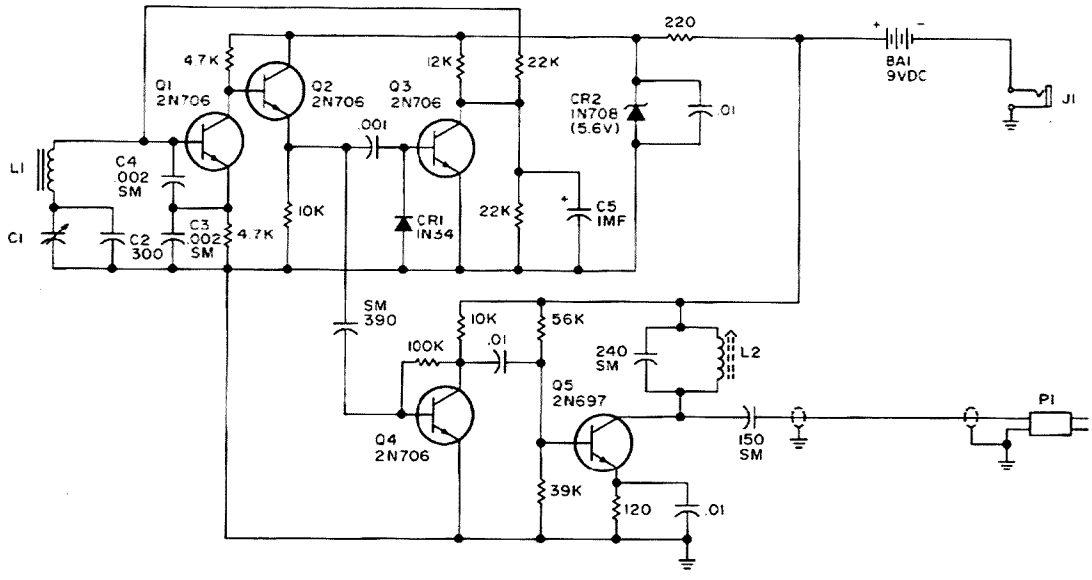

Fig. 1. Schematic diagram of the transistorized vfo.

Schematic Diagram Notes

L1 – toroid coil 1/2" od 'E" material core. Amidon associated core T-50-2. Winding 45 turns number 28 enamel wire spaced over entire core.
C1 – 100 pF maximum variable capacitor. Johnson type S 148-6 or equivalent. Remove plates as required to provide desired bandspread.
C2 – Silver mica – approximately 300 pF. Adjust exact value to set lower tuning range to 3.5 MHz.
C3, C4 – Silver mica 2000 pF.
C5 – Miniature electrolytic 1 μF at 10 VDDW.
L2 – 40 turns number 28 enamel wire on 3/8 diameter slug tuned form.
CR2 Zener diode, 1N708 – 5.6 volts. (Motorola HEP-103 useable)
BA1 9 volt transistor battery
J1 Miniature jack
P1 Two prong plug with standard .486 pin spacing for crystal sockets or other to match companion transmitter.
Q1, Q2, Q3, Q4 2N706
Q5 2N697

These were .002 μF in the unit built, but their value could probably be increased to result in even more decoupling of the tuned circuit from the oscillator transistor.

Coupling off the collector of Q5 requires that the load for the vfo be a high impedance such as the grid of a vacuum tube amplifier or frequency multiplier. For low impedance output a link wound over the B+ end of the L2 should do the job if it is necessary to drive a coax line.

The supply voltage for the first three stages is regulated by a zener diode. With a battery power supply in fixed station service this is probably not absolutely necessary, but the zener does provide a convenient means of supplying the first stages with a constant supply.

Mechanical Design

The mechanical layout of a vfo is extremely important if variations in frequency due to shock and thermal changes are to be avoided. Many methods have been used and some have gone to rather elaborate lengths to achieve mechanical stability. With transistors and a printed circuit board for the layout the mechanical design is simplified. The circuit board ties down the wiring and all the components except the coil and tuning capacitor. It then remains to devise suitable mounting arrangements for these two.

The toroidal coil is handled by connecting it to the circuit board and then encapsulating it and its leads to the board with epoxy cement. This provides a very rigid mount mechanically and is quite simple to use. In addition to the coil, the three silver mica capacitors in the tuned circuit are spoxied to the circuit board to enhance their machanical rigidty. This expedient is probably not absolutely necessary, but the excess epoxy from the coil fastening operation can be well used here.

The mechanical mount for the tuning capacitor is often the shortcoming of an otherwise good vfo. Since the epoxy used to hold down the coil and capacitors on the

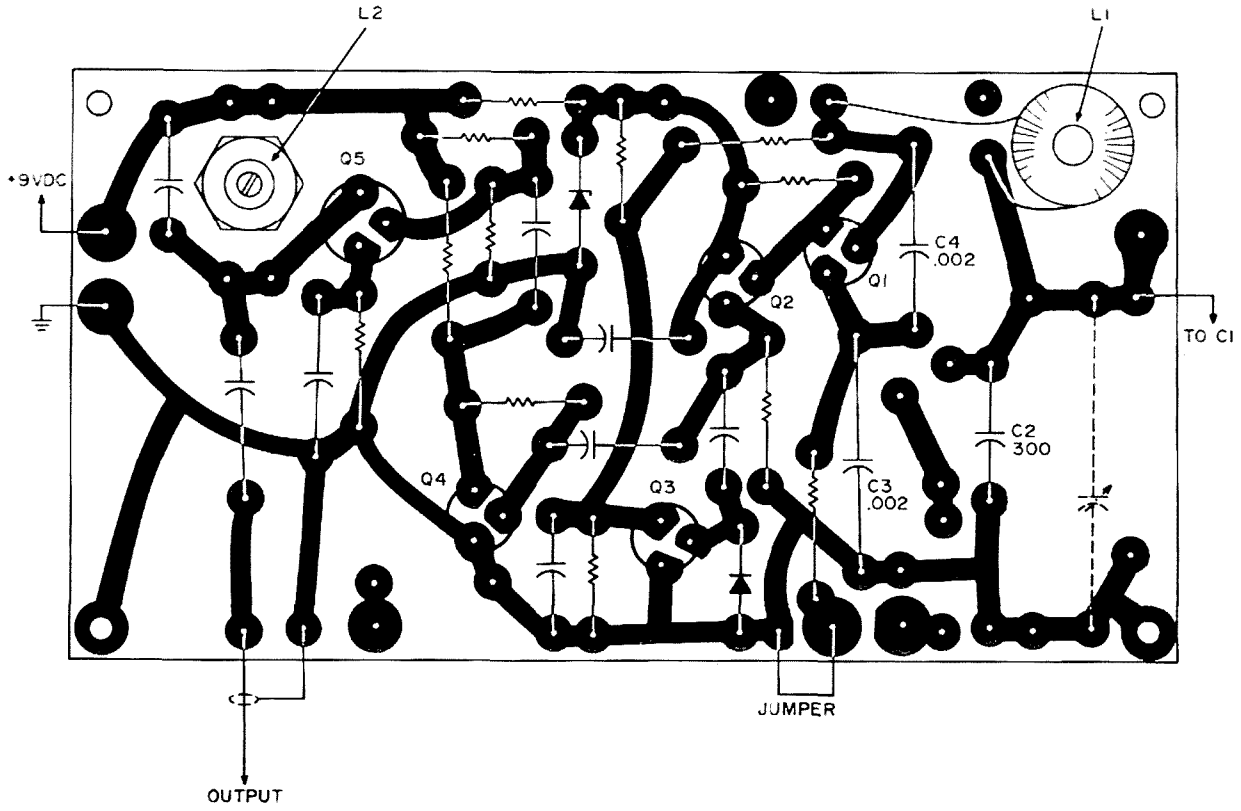

Fig. 2. Circuit board and parts placement for the vfo. Major values are noted to serve as a key.

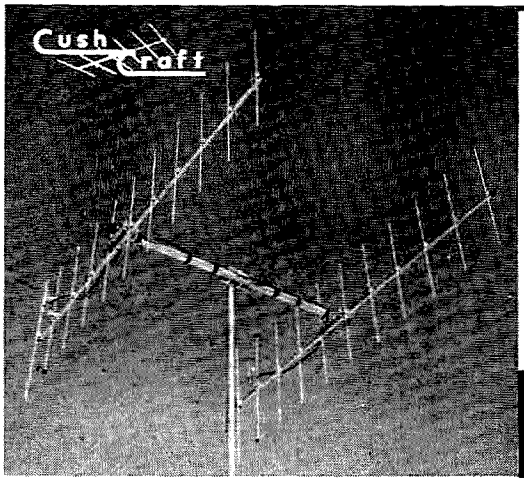
circuit board proved to be so sturdy, I reasoned that it might also be used to mount the variable capacitor. The shaft of the capacitor is mounted to the vernier dial coupling and its ceramic body fastened to the chassis by a liberal application of epoxy through a hole approximately 1/2" in diameter immediately above the capacitor. A sketch of the mounting arrangement is shown. A mounting bracket would probably work, but the direct chassis mounting eliminates the mechanical variations which might be present in a secondary connecting member.



I obtained the epoxy used throughout at the local hardward store; it's sold under the trade name "E-POX-E STEEL." [1] Preliminary tests on a sample showed that it did not cure very well when allowed to dry overnight as suggested in the directions, but a test cure in the kitchen oven at 200F proved to be quite good, and the drying time at the elevated temperature was under a half hour. Some capacitance is added to the toroid coil by the encapsulant so final padding adjustment on the tuning must be done after the coil is epoxied in place.

I suggest that the printed circuit board layout be used as shown. The wiring can get quite complicated without a circuit board, and point to point wiring can be unstable for vfo use. I made no attempt at miniaturization in laying out the board and it could have been smaller. The size was chosen to be compatible with the remainder of the station gear and the dial on the vfo itself.

Once the board has been assembled, the remainder of the wiring is minimal with the only connections being to the variable capacitor, the battery and the output cable. It will be noted that some unused holes are shown on the board. These are a result of some ideas which did not work out in the final circuit design. One of these necessitates jumpering the emitter resistor of Q1 to ground (see reference to oscillator keying below).

The assembled circuit board is mounted on top of a standard minibox which is 3 X 5¼ X 2" high. A hole must be drilled in one corner of the top of the box to clear the output slug tuned coil. Mounting the board on top leaves the inside open for the tuning

capacitor and the battery. The vernier dial is mounted to the front apron of the box and the output cable exits at the rear with a jack on the rear apron for external control of the oscillator.

The battery mount was made using the top of an old battery soldered to a terminal strip. The nine volt battery then plugs into this arrangement. While this mounts the battery simply, a more rugged mount would be more suitable for mobile use.

Results and Conclusions

One of the problems I encountered with the vacuum tube circuit this vfo has replaced

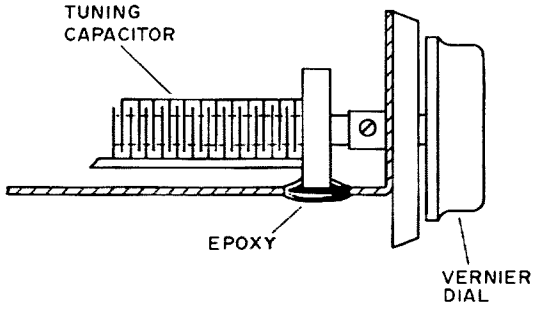

Fig. 3. Details of rigid capacitor mount.

was a slow thermal drift each time the oscillator was turned on during a QSO. This sort of short term frequency variation is common with tube circuitry and high levels of oscillation. Drift with the semiconductor vfo is practically non-existent on both a short and long term basis.

In normal operation the vfo is allowed to run continuously and a subsequent stage in the transmitter is keyed. This does not allow break-in operation although the vfo has been keyed and only a very slight chirp can be detected. The chirp is dependent on the load presented by different settings of exciter tuning and suitable adjustment of the multiplier stages does eliminate the chirp almost entirely. This sort of arrangement is by no means a sound solution to the chirp problem, however, and for best operation you should run the vfo continuously or provide a suitable method of differential keying.

This vfo should be used to drive a frequency multiplier in the companion transmitter and not straight through on 3.5 MHz. For eighty meter operation, a half frequency design of 1.8 MHz should be built. Since I wanted operation only on 40 meters and above I chose the 3.5 MHz output frequency.

The above precautions are almost standard practice for ham vfo's, and the many attempts to bypass them have been futile. In other words, the old handbook warning against trying to key a vfo still holds.

This oscillator has been a very worthwhile replacement for the old tube model in the station transmitter. As mentioned, the output was adequate to drive my rig, but some transmitters in the Novice class might require a little more drive. The output level is dependent on supply voltage; increasing the battery to 12 or 18V will provide additional drive. However, the supply should not be much over 20V unless a 2N697 is used at Q4 in place of the 2N706 shown on the schematic diagram. Different bias resistors for Q5 as well as a larger dropping resistor for the zener diode would be required if the supply is increased. An untuned vacuum tube buffer amplifier might be more effective to couple into an existing transmitter if the output of Q5 is not enough alone. ...W9ZTK

MORE LETTERS

It was very gratifying to see my latest article on SSTV equipment in print in the September issue of 73 Magazine. I am already receiving many compliments on it and that 73 is publishing timely articles on SSTV. From the correspondence and conversations with chaps who are building this camera I have been getting several questions in regard to the Plumbicon deflection coils.

In the diagram the horizontal sync pulse drawn near Q4 is 5 *milli*seconds, not 5 microseconds. The vertical sync pulse drawn near the diode of Q6 is 45 *milli*seconds, not 45 microseconds. In the upper right hand paragraph above the schematic Fig. 4, the third sentence should read as follows: *Each horizontal coil has approximately 620 turns of #36 wire.* The fourth sentence should read: *Each vertical coil has approximately 800 turns of #36 wire.*

I would also like to add that the .050 inch thick deflection coil form is used for the vertical coils during winding. A form of the same dimensions but only .030 inches thick is used as the window opening form for the horizontal coils. This second window form was omitted from the article.

That is about all the comments from K7YZZ for now, Wayne. See you on 20 SSTV sometime soon, I hope.

We have some very, very dishonest fellow amateurs on our airwaves. I happened to be working a very chirpy Novice lately and I reported to him what I was hearing. We spent about 30 minutes discussing his chirp problem and the possible causes of it. He reported that I was the first one to tell him that he had chirp and thanked me for telling him. I heard the same guy a few nights later, and his beautiful ac chirp was still there. I called him and he did everything but call me a liar, saying he had asked almost everyone whom he had worked since our first QSO and was told his signal was very clean, with no trace of chirp. Now the guys that he had worked were either lying to him or very ignorant, not to know a very noticeable chirp when they hear one.

I just cannot believe these guys would lie to him. If my signal sounds lousy, I want you to tell me and I'm sure going to tell you if yours sounds lousy, hopefully before the FCC does, because that's the worst way to find out. So come on, guys, let's help each other out and most of all let's help out the beginners, because they need the help the most, especially now that they will be using VFO's at least 50% of which will probably be ancient drifters that are cheap and easy to come by. Spend a little time working the Novice bands and let's get them started out on the right foot.

Steve Morgan WA8QNR

Nothing special (i.e., no axe to grind) but thought I would mention that I feel the Sept. 72 73 just received is one of the best balanced (opinion, articles, scope, etc.) to date — and real pro. appearance.

Will Rassbach WA7GRN
Seattle WA

I just thought I would include a little note to let you know that my selection of your magazine was not just chance. I have seen and read all the leading ham publications. I've even been given a free 6 month subscription to C.Q. As far as I am concerned they just don't match up to yours, for good, overall total information on the "state of the art." I enjoy the columns on most all subjects, but I would like to see more in the way of operating hints for Novices. Like tips on DXing, antenna systems, and just overall coverage for the newcomer.

William Armstrong WN8NKT/4
Shaw AFB SC

With reference to the October issue, I read with interest W2GOM's explanation of how a Clapp oscillator works. It is amusing to note that the model he develops couldn't possibly oscillate without a 180 degree phase shift, a point he was trying to refute! Although a crystal, by itself, can't develop a 180 degree shift, in combination with the other capacitors in the circuit it can and does.

That tutorial article should be interesting.

Gilbert L. Boelke W3EUP
West Seneca NY

I'm with you on the Amateur Extra Class license. While in high school in 1925 I got a 1st Class Telegraph, followed by a 1st Class Fone. Worked at them both, even after I went back to school for an engineering degree several years later. Present call acquired in 1932, Class A, then Advanced. Have worked over 45 years in amateur radio, AM, SSB, CW. Kept current in all. Why should you, I, or any serious, knowledgeable amateur, be penalized? I believe the FCC action, sponsored by ARRL, is discriminatory. While I would have no trouble with the exam, including code, I refuse to take it.

J. Alan O'Neil W6GIX
San Francisco CA

I am a collector . . . I collect magazines devoted to amateur radio. Mine is not a large or particularly exotic collection, but I think you might be interested in a portion of its contents. The most expensive single copy I have is an Aug. 72 issue of "rpt." I paid $6 for it. I didn't intend to pay that much for the issue, as I was led to believe there would be 23 subsequent issues included in the price.

I also have a similar issue of "FM" which also seemed to cost a larger amount than I intended to pay.

As of this date, I am not a regular subscriber to 73. I found that several years ago I received several free issues of 73 after paying so much for my "FM" issue; and, it is said that history has a way of "rpt"ing itself.

I doubt very much that I will continue to collect limited editions . . . they are getting too expensive.

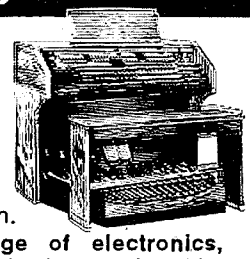
Dave WB9DNI/WA7GSG
Aurora IL

P.S. Have you heard about the new publication devoted to Citizens Band Repeaters? I believe it will be published in Michigan, by a former amateur.

No, no free issues of 73 this time. And, if you'd read 73 or the Repeater Bulletin you would have been warned that special interest magazines are a big gamble as far as subscriptions go. Many thousands of amateurs have been taken in the past short-lived publications. If you watch 73 carefully, you will find that we do not recommend publications that look like they are not going to be able to make it.

DXer Magazine will make it. We run ads for Gus and his nice little publication because we know that he is going to be there and that readers who depend on 73 will not be disappointed. World Radio looks good — and is fun to read. I don't know how Armand gets all those interesting DX stories, but he does. . . .wayne.

The FM bug is following quite closely. I recently acquired an RCA Carfone CMV-4F xmtr-rcvr single frequency, presently on 154 MC and modified for 12V. I plan to remove the dynamotor and vibrator. I have a power supply which is adequate for base station use. I also have a manual. I would appreciate any info concerning conversion to 2 meters.



Although I am only a Novice I hope someone can give me a little help. I am working for my General license now.

Also I was considering using the Carfone on 2 meter CW by grid block keying a couple of xmtr stages. Comments on this by anyone would be appreciated.

Now...the most enjoyable, do-it-yourself project of your life—a Schober Electronic Organ!

You'll never reap greater reward, more fun and proud accomplishment, more benefit for the **whole family** than by assembling your own Schober Electronic Organ. **You need no knowledge of electronics, woodwork or music.** Schober's **complete** kits and crystal-clear instructions show **you** — whoever you are, whatever your skill (or lack of it) — how to turn the hundreds of quality parts into one of the world's most beautiful, most musical organs, worth up to twice the cost of the kit.

Five superb models, with kit prices from $500 to around $2,000, each **an authentic musical instrument actually superior to most you see in stores.**

Join the thousands of Schober Organ builder-owners who live in every state of the Union. Often starting without technical or music skills, they have the time of their lives —first assembling, then learning to play the modern King of Instruments through our superlative instructions and playing courses.

Get the full story FREE by mailing the coupon TODAY for the big Schober color catalog, with all the fascinating details!

The *Schober* Organ Corp., Dept.
43 West 61st Street, New York, N. Y. 10023

☐ Please send me Schober Organ Catalog.

☐ Enclosed please find $1.00 for 12-inch L.P. record of Schober Organ music.

SOLUTION TO CRYPTOGRAM

on page 117 of the November issue, a quote from W2NSD's editorial in that issue:

> The heavy hand of an insensitive government has just dealt a cruel blow to the most exciting and fun aspect of amateur radio in many, many years.
>
> Wayne Green

NEW NOVICE REGS

In the Matter of Amendment of Part 97 of the Commission's Rules to provide for expansion of the telephony segments of the high frequency amateur bands.

Adopted: September 27, 1972;
Released: October 2, 1972
By the Commission: Commissioner Johnson concurring in the result.

1. The Commission adopted a Notice of Proposed Rule Making in the above entitled matter on February 24, 1971, which was published in the Federal Register on March 6, 1971 (36 FR 4511). Interested persons were invited to file comments on or before June 1, 1971, and reply comments on or before June 18, 1971, respectively. The Notice proposed to expand the General-Conditional Class sub-band operator privileges in four amateur radio high frequency bands, to provide additional Amateur Extra and Advanced Class sub-bands in those high frequency bands where they do not exist, and to make other adjustments to the allocations of high frequency bands to facilitate the accomplishment of these proposals and additionally to expand the telephony sub-allocations in the five amateur radio high frequency bands from 3.5 to 29.7 MHz.

2. Formal comments were received from persons and amateur radio organizations within the United States and foreign countries. Many comments simply urge the adoption, or the rejection, of the proposals. Others endorse certain proposals and request that others not be adopted. Many propose alternate frequency band allocation plans. Since the comments received were so numerous, it is not practicable to discuss each herein. However, every comment filed has been given careful consideration.

3. Reactions to the proposals expressed in the comments, were highly mixed. Some, identifying themselves as telegraphy enthusiastis, opposed the proposal, usually citing the resulting reduction in the effective use of the telegraphy bands as the reason. Others, identifying themselves as telephony enthusiasts, supported the pro posal, usually giving the crowded telephony bands as the reason. Proponents of both sides of the issue agreed that telephony expansion would be at the expense of telegraphy operation, with the telegraphers aruging that their preferred mode of radiocommunication would be impaired and the telephony advocates aruging that telegraphy is outmoded and unnecessary.

4. All of the HF bands from 3–30 MHz have predictable propagation characteristics depending on the period of the sunspot cycle, season, time of day, and the order of the frequency band itself. At times, some bands are primarily useful for short-distance radiocommunication, even though under those circumstances signals cross national boundaries. At other times, even the two main lower frequency amateur bands (3.5, 7.0 MHz) become international in character through long distance ionospheric propagation of signals. During the low period of the sunspot cycle, congestion in the lower frequency bands becomes more critical as the maximum usable frequency (MUF) decreases. Bands above 14 MHz, are generally considered internationa in nature by reason of long distance propagation of signals in these bands for a large percentage of the time.

5. A considerable number of comments were received from organizations located in other countries, and a delegation from one country paid an official visit to the Commission to discuss the ramifications of the Notice. The comments and information of other countries are worthwhile, and provide an added insight to what is normally considered a domestic matter. It is recognized that there are no formal internationally agreeed sub-allocation plans which reserve certain portions of any of these bands for one type of emission or the other. There are, however, "gentlemen's agreements" among amateurs in various parts of the world (Region 1 in particular) which have worked out well in practice in maintaining order and providing efficient utilization of the various amateur bands. Only a few countries, having large numbers of amateurs, provide sub-allocations in domestic regulations. The International Radio Regulations, to which the United States is a signatory administration, provides only band allocations to the Amateur Radio Service for the three Regions. In reaching a judgment on a matter with implications which could result in a lessening of international good will among amateurs, as well as a reduction of efficiency of utilization of the spectrum, we would be doing amateurs generally a disservice were we to disregard physical phenomena. Certainly we would be short-sighted if we totally disregarded opinions such as that of the International Amateur Radio Union, Region 1 Division, which pointed out,

> "The downward shift to 14,150 kHz will cause severe interference to operation in Region 1. With the high power and large number of US stations it will not be possible for foreign stations to operate above 14,150 kHz when propagation conditions enable USA stations to be heard. The consequent move downward in frequency by Region 1 Telephony stations will undoubtedly cause breaches of the voluntary IARU Region 1 band plans which have been in satisfactory operation for a number of years."

A similar opinion was expressed by the Radio Society of Great Britain and others.

6. Therefore, we conclude that a significant expansion of the telephony segments within the high frequency amateur bands would be at the expense of the telegraphy segments. Furthermore, we are of the opinion that the traditional amateur telegraphy radiocommunication mode must not be compromised. The rationale for this conclusion is well summarized in a quotation from a letter to the Chairman of the Commission from the Director of the Office of Telecommunications Policy:

> "While the use of CW radio telegraph communications has been replaced in most radiocommunications services with more sophisticated techniques over the years, this is not considered sufficient reason to justify the curtailment of such operations among U.S. amateurs. Knowledgeable communicators agree that when other types of high frequency radiocommunications fail CW transmissions are likely to get through. Thus, even though other techniques might be relied on first, it still would be wise to retain a pool of U.S. citizens skilled in CW operations as a resource in reserve. Amateur operators, with their past superb record of serving the public interest when needed, are considered the best means for preserving this skill."

7. We find that amateurs have been resourceful in effectively operating in the overcrowded high frequency bands. The vast majority have adopted spectrum conservation receiving and transmitting techniques. The nearly

universal incorporation of suppressed or reduced carrier types of SSB emission and other frequency conserving capabilites, such as highly selective receivers and directional antennas, has permitted more operators to conduct reliable radiocommunication over greater distances. Nevertheless, the question of how the existing high frequency amateur bands can accommodate even a relatively modest increase in the number of stations is now clearly in view. As evidenced by the petitions and comments, even the present number of amateurs authorized for telephony emissions on the high frequency bands at times far exceeds the capacity of the allocated A3 and F3 emission segments. We see no technological developments on the horizon to enable more simultaneous telephony amateur radiocommunication within the present sub-allocations, although this is in itself a challenge to amateurs. Any proposed amendment to Article 5 (spectrum allocation) of the International Radio Regulations to allocate additional portions of the high frequency spectrum to the Amateur Radio Service, are at best some years in the future and only speculative. The only practical solution appears to be one of limiting access to the more crowded bands only to higher class licensees. Until such time as this becomes necessary, amateurs are encouraged to utilize other emissions and frequency bands during times of severe overcrowding of the telephony segments. Furthermore, we strongly urge that the VHF and UHF bands be utilized for all local radiocommunication; that the minimum power rules be strictly observed to minimize interference; that full carrier double sideband emission not be used in the lower four HF bands except in an emergency; and that all amateurs exercise good judgment and restraint when selecting a frequency and emission for their operation.

8. Accordingly, we conclude that the high frequency spectrum available to the Amateur Radio Service does not allow treatment which would significantly alleviate the problem of overcrowding in telephony radiocommunication through expansion of sub-band allocations. We are of the opinion that a small increase for telephony operation in the 3.5 and 7.0 MHz bands can be accommodated without causing a serious deterioration in telegraphy operation. We believe any telephony expansion of the 14.0 MHz band would result in a serious degradation to non-voice radiocommunication, and *no* expansion is adopted. Numerous comments from amateurs outside the United States express opposition to any telephony expansion by the United States, particularly in the 14.0 MHz band. Should U.S. licensees be permitted to operate in the unofficial, but widely observed, non-US telephony sub-band between 14.1 and 14.2 MHz, they predict a movement by non-US telephony stations into the 14.0 to 14.1 MHz segment, causing a deterioration in telegraphy radiocommunication and a general breakdown in inter-Region cooperation. This must not take place. We also find the 21.0 and 28.0 MHz frequency bands not to be sufficiently crowded to warrant an expansion of the telephony segments.

9. Comments from Canadian amateurs express concern for the resulting impact of expansion of the telephony segments available to US amateur below 3.8 MHz. In addition to the 2.8 to 4.0 MHz telephony sub-band authorized for both US and Canadian amateurs, they are also permitted 3725 to 3800 kHz. This concern is expressed in the comments from the Director of the Canadian Division of the American Radio Relay League. Although we do not agree entirely with the implied necessity for Canadian amateurs to operate in different sub-bands, their comments are taken into account.

> "Canadian amateur operators have always made extensive use of the 3.5 MHz band. The size of the country and the low density of population have precluded the use of other frequencies, such as 144 MHz, since they did not provide adequate coverage. It is perhaps the most widely used amateur band in Canada for internal communication, in spite of the fact that 25 kHz, (3725–3750 kHz) are shared with American Novice operators. While Canadian voice operation could and undoubtedly would be moved to some lower portion of the band such as 3650–3700 kHz, in order to avoid Novice interference, there would be less space available for other modes as a result . . . "

10. The Notice proposed 3750 to 3775 kHz for Amateur Extra Class and 3775 to 3875 kHz for Amateur Extra and Advanced Classes, an expansion of 50 kHz for telephony privileges. The American Radio Relay League, and others, recommend an expansion of only 25 kHz, limited to Amateur Extra Class operators only. This would authorize some 12 thousand higher class licensees to operate within the 3775–3800 kHz sub-band. In recognition of the Canadian operators' comments, we are of the opinion that the American Radio Relay League recommendation is a workable compromise, and we are therefore adopting it.

11. We conclude that the 7.0 MHz telephony sub-band can be expanded as proposed to the extent of permitting A3 operation between 7150 and 7200 kHz. While the comments heavily favor the adoption of this proposal, objections were also made, although to a lesser extent, by Canadian amateurs, because telephony operation is authorized in Canada by the Department of Communication for the same segment. Since the expanded telephony segment of 7150 to 7200 kHz have been heavily utilized for Novice Class A1 operation, and since only a limited number of higher class licensees will be permitted to operate within the new telephony segment, the expansion is acceptable. As a result of this action, the Novice band is relocated to 7100 to 7150 kHz.

12. The proposal to provide a telephony sub-band below 7100 kHz for contacts with stations in Region 1 and 3, is not being adopted. Numerous comments pointed out that the proposal, if adopted, would make inter-regional radiocommunication with foreign stations occupying these frequencies more difficult since Region 2 stations would overload the segment. The proposal to permit telephony operation between 7075 and 7100 kHz for American stations located outside of Region 2 is adopted, however.

13. In the interest of encouraging beginning amateur operators to gain experience in telegraphy radiocommunications, a new Novice privilege segment is adopted for 28.100 to 28.200 kHz. Observations indicate that the segments 21.200 to 21.250 MHz and 145–147 MHz are lightly occupied for Novice operation and are therefore deleted. In light of these changes, and because of the relocation of the Novice 7.0 MHz sub-band, the requirement that the transmitter be crystal controlled is removed. We are of the opinion that the technical state of the art for calibrated variable frequency generating devices in the Amateur Service permits this change and re-crystalling of the many thousands of Novice Class transmitters is unwarranted. Additionally, this will enhance the operating effectiveness of Novice operation through reduction of interference and increased operating flexibility. Since the distinctive "N" designator in a Novice Class call sign prefix is easily recognized in the Service, Novice operators are cautioned to observe strictly the authorized frequency sub-allocations for Novice Class licensees. While amending paragraph 97.7(d), we revise the wording for the 75 watt power limitation to generalize its application to other am-

plifying devices in addition to vacuum tubes.

14. As pointed out by a number of respondents, the 28 MHz frequency band does not offer itself to providing meaningful exclusive operating segments for upgrading incentives since the frequency availability problem is not of comparable magnitude as that encountered on the other high frequency bands. For this reason, the proposed establishment of exclusive operating frequency privileges for Amateur Extra Class and Advanced Class licensees is not adopted. With thousands of amateur radio operators upgrading to Amateur Extra Class and tens-of-thousands upgrading to Advanced Class, while the number of General and Conditional Class licensees is decreasing, adjustments to the sub-band allocations must be made in order to retain the incentive principle. Additional adjustments will be made periodically in the future as the upgrading movement continues. Allocations follow a pattern of apportionment of the telephony segments into three sub-bands in the case of 3.5 MHz and 21.0 MHz; one restricted to Amateur Extra exclusively; one restricted to Amateur Extra and Advanced; and one available to General/Conditional and Extra/Advanced. These-sub-band apportionments are determined by considering the number of individual licensees in each group having privileges to each sub-band weighted in favor of the higher classes. Proposed telephony sub-bands restricted to the Amateur Extra Class in the 7.0 MHz and 14.0 MHz bands are not adopted because the application of the apportionment pattern to these smaller telephony segments would result in Amateur Extra Class sub-bands so small as to be practically useless.

15. Comments received in response to the proposed reduction in the Amateur Extra-restricted telegraphy sub-band were almost entirely opposed. Reasons cited included observations to the effect that the proposed 10 kHz sub-band was too small to be meaningful, and that the restricted telegraphy sub-band was their primary incentive for upgrading. We find these comments persuasive and in agreement with our own observations. The proposal is not adopted herein, and the sub-band remains at 25 kHz.

16. We find the attached amendments to the rules are necessary and desirable and in the public interest. Authority for adoption of these amendments is contained in Sections 4(i) and 303 of the Communications Act of 1934 as amended.

17. Accordingly, IT IS ORDERED, that effective November 22, 1972, Part 97 of the Commission's Rules is AMENDED as set forth in the attached Appendix.

18. IT IS FURTHER ORDERED, that in addition to the fifteen petitions set forth in the heading to the proceeding, the pending petition of Mr. Frederick J. Hagen, filed February 1, 1971, RM-1748; and the pending petition of Mr. George W. Flyer, filed November 1, 1971, RM-1873; and the pending petition of Mr. William G. Welsh, filed November 8, 1971, RM-1880, have been fully considered and, to the extent that they are at variance with the rule changes adopted, they are DENIED.

19. IT IS FURTHER ORDERED, that this proceeding IS TERMINATED.

Federal Communications Commission
Ben F. Waple
Secretary

Attachment

NOTE: Rule changes herein will be covered by T S VI(72)-1.

APPENDIX

Part 97 of the Commission's Rules is amended as follows:

1. Section 97.7(a) and table, subparagraphs (d)(1) and (d)(2) are revised to read as follows:

§ 97.7 *Privileges of operator license*

(a) *Amateur Extra Class and Advanced Class.* All authorized amateur privileges including exclusive frequency operating authority in accordance with the following table:

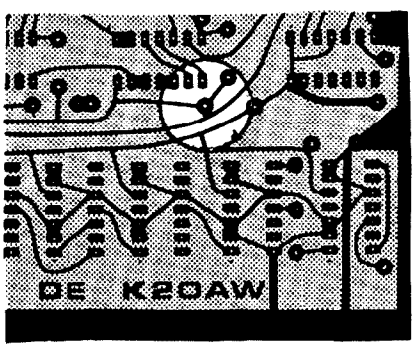
FREQUENCIES	CLASS OF LICENSE AUTHORIZED
3500–3525 kHz	
3775–3800 kHz	
7000–7025 kHz	
14000–14025 kHz	Amateur Extra
21000–21025 kHz	Only
21250–21270 kHz	
3800–3890 kHz	
7150–7225 kHz	
14200–14275 kHz	Amateur Extra
21270–21350 kHz	and Advanced
50–50.1 MHz	

(d) *Novice class.* Those amateur privileges designated and limited as follows:

(1) The power input to the transmitter final amplifying stage supplying radio frequency energy to the antenna shall not exceed 75 watts, exclusive of power for heating the cathode of a vacuum tube(s).

(2) Radio telegraphy is authorized in the frequency bands 3700–3750 kHz, 7100–7150 kHz (7050–7075 kHz when the terrestrial location of the station is not within Region 2), 21,100–21,200 kHz, and 28,100–28,200 kHz, using only type A1 emission.

2. In Section 97.61, the table in paragraph (a) is amended and (b)(10) is added to read as follows:

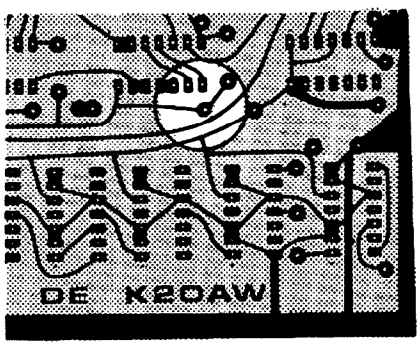


§ 97.61. *Authorized frequencies and emissions*

(a)

Frequency band	Emissions	Limitations(see paragraph (b))
kHz		
1800–2000	A1,A3	1,2
3500–4000	A1	
3500–3775	F1	
3775–3890	A5,F5	
3775–4000	A3,F3	4
7000–7300	A1	3,4
7000–7150	F1	3,4
7075-7100	A3,F3	10
7150–7225	A5,F5	3,4
7150–7300	A3,F3	3,4
14000–14350	A1	
14000–14200	F1	
14200–14275	A5,F5	
14200–14350	A3,F3	
MHz		
21.000–21.450	A1	
21.000–21.250	F1	
21.250–21.350	A5,F5	
21.250–21.450	A3,F3	
28.000–29.700	A1	
28.000–28.500	F1	
28.500–29.700	A3,F3,A5,F5	

(b)



(10) The use of A3 and F3 in this band is limited to amateur radio stations located outside Region 2.

AUTHOR'S CORRECTION

On page 82 of the November **73**, in the article "Frequency Synthesizer III," Fig. 13 contains an error. One solder pad was shown merging with a wire (see detail at left). There should be no connection between them, as at the right.

NON-SQUIRRELY TWO METER PREAMP

During my years of experimenting with 2 and 6 meters, I have built a number of things such as preamps and converters using tubes, nuvistors, transistors and FET's, including the well-known 3N128 Mosfet. I recently tried a circuit using an MPF-107 FET in a common source configuration. The circuit herein described, if followed closely, will produce a non-critical two meter preamp second to none. Nor is there any neutralization required.

This preamp can be built on a home brew printed circuit board with ease. The board need be only about 2½ in. square. All leads should of course be kept as short as possible. The coil forms should be quarter inch with white powdered iron cores. The preamp should draw about 15 mils. Tuneup is accomplished by tuning for maximum first limiter current, or maximum S meter reading. This circuit is basically for 146.94 MHz, but should be adaptable for any two meter frequency.

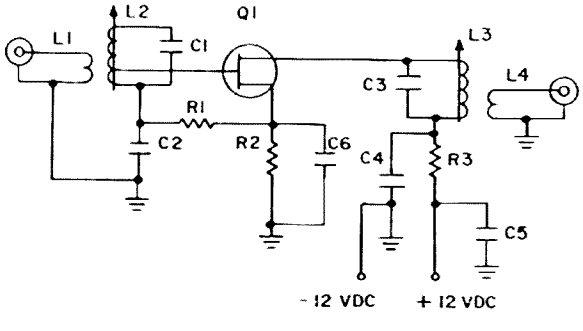

Fig. 1. 2m FM preamp. L1 & L4, 2T No. 22 hookup on cold end of L3; L2 & L3, 3½T No. 16 spaced the dia. L2 & L3 must be wound opposite directions; C-1, 10 pF; C-2, 470 pF; C-3, 10 pF; C-4, 470 pF; C-5, .01; C-6, 470 pF; R-1, 220 ohm ½W; R-2, 370 ohm ½W; R-3, 22 ohm ½W; Q-1, Motorola MPF-107 or HEP 802.

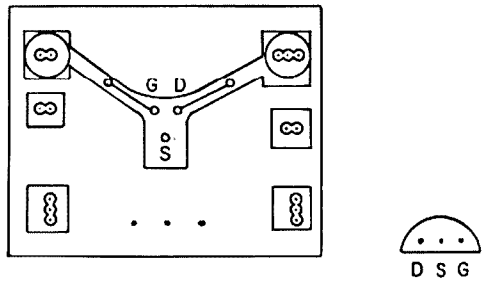

Fig. 2. Printed circuit layout. Drain and source interchangeable.

I have been unsuccessful in all attempts to make the preamps break into oscillation while properly connected. This unit will bring a one microvolt sensitivity to less than four- tenths microvolts for copyable signal.

This article is intended basically for the FMer but should not be overlooked by the SSB and AM boys either. There are several of these preamps in use today here in Wichita by very satisfied base stations and mobiles.

I would like to express my appreciation to Wayne McVay (WAØPLY) for his part in the discovery of this very successful circuit. Apply your 12V dc and hear signals that you never knew were there.

3rd PARTY REGULATIONS

In the matter of inquiry into the extent to which amateur stations should be used on behalf of non-amateur organizations.
Docket No. 19245, RM-1687
Released October 11, 1972

By the Commission: Commissioner Johnson dissenting; Commissioner Reid absent.

1. On April 28, 1971, the Commission issued a Notice of Inquiry in the above-entitled matter. The Notice which was published in the Federal Register on May 8, 1971 (36 F. R. 8611) requested that comments be filed by interested parties by July 1, 1971. Subsequently, the time for filing comments was extended to August 31, 1971. Seventy-five comments were filed by both individuals, amateur organizations, and other organizations which have in the past used the facilities of amateur radio stations.

2. The Notice of Inquiry was the proximate result of §97.39 which prohibits certain organizations from both obtaining an amateur station license or having an amateur operator use his station on behalf of those organizations. One of the effects of this Rule is to prohibit amateur operators from using their stations on behalf of such parties as the Eye Bank, American Red Cross and the March of Dimes as well as commercial businesses.

3. Our Notice requested comments regarding whether any restriction on the use of amateur radio stations by non-amateur organizations is needed. We also requested comments on what those restrictions should be. The Notice further related to the fact that unlimited operation on behalf of organizations (third party communications) could lead to the creation of large numbers of new networks which would create additional unwarranted interference on the amateur bands.

4. The comments received in the Docket suggested many solutions to the problem of which organizations, if any, should be allowed to use amateur radio facilities. The comments covered the full range from no third party communications to any communications that individual amateurs wish to carry. Most of the comments advocated a position between those two positions. Three comments suggested that amateur radio be used on behalf of non-amateur organizations but only when normal communications are unavailable. Many other comments suggested that third party communications be allowed for charitable nonprofit organizations but only during emergencies. A majority of the comments agreed that it is not a sound practice to allow commercial organizations to use amateur radio stations, but there was no consensus as to what other organization should have use of amateur stations.

5. The Commission believes that the best solution lies between the extremes of prohibiting entirely third party communication and permitting unlimited third party operations. To prohibit entirely third party traffic would tend to stifle one of the basic purposes of the Amateur Radio Service which is to provide a voluntary non-commercial radio service. But to allow all third party communications would tend to cause increased congestion in the Amateur bands.A basic principle permeating our rules and the international radio regulations is that amateur radio shall not be used for any pecuniary interest to any party or for commercial communications. The international rules specifically provide that amateur radiocommunications must be of a technical nature or remarks of a personal character for which, by reason of their unimportance, recourse to a public telecommunications service is not justified. There can be no legitimate reason for an amateur station to carry message traffic of a commercial nature. Radiocommunications, the sole purpose of which is to facilitate regular business or commercial activities, do not enhance the intended purpose of the Amateur Service and should not be allowed except for an emergency communication as defined in our rules

6. Several comments were received which suggested that the thrust of the Commission's Notice of Inquiry was to censor the Amateur Radio Service. These comments suggested that any categorization of groups, some of which could use amateur radio facilities and others who could not, would be in violation of §326 of the Communications Act of 1934 which prohibits censorship of radio communications. It has been established, however, that eligibility restrictions and reasonable rules limiting communications to those consistent with the purpose of the radio service involved are within the scope of the Commission's authority. See, *Lafayette Radio Electronics Corp. v. United States,* 345 F2d 278 (2nd Circ. 1965). Moreover, it is not only permissible but an affirmative duty of this Commission to classify radio stations and to regulate the nature of the radiocommunication service that is to be rendered by stations in that class. See §303(a) and (b). Our rules adopted today regarding commercial third party traffic merely regulate generally the nature of the radio communication service which may be rendered by amateur stations.

7. The Rules adopted today will delete the phrase "nor for its use" which is contained in §97.39. The result of this action will make §97.39 a rule concerned only with who or what organizations may obtain a license. The amended §97.39 will not be directed to permissable communication nor to the use of an amateur station.

8. We are adding a new section, §97.114, which will both prohibit commercial third party traffic and clarify the permissible international third party traffic. As to the provisions of subparagraph (a) concerning international third party traffic, these rules simply incorporate the already existing international rules. As such they make no change in permissible communications and they are therefore considered to be of an editorial nature. Subsection (c) of §97.114 prohibits corporations, companies, associations and other organizations engaged in commercial activities from using amateur radio facilities. It will not prohibit the use of the Amateur Radio Service on behalf of organizations such as the Eye Bank and the American Red Cross except for traffic which relates to the regular business affairs of those organizations. Subparagraph (b) will prohibit amateur control operators or station licensees from receiving any compensation including a salary or reimbursement for non-collect telephone calls for operating an amateur station for transmitting or delivering third party traffic. This provision explicitly sets forth the fact that both domestic and international amateur traffic must not be handled with a pecuniary interest in mind.

9. To prevent unnecessary confusion as to what is meant by third party traffic, we are adopting a definition of that term and are making editorial changes in §97.79(d).

10. The provisions of §97.114(b) and 97.112 will clearly prohibit the American Radio Relay League's long

standing practice of providing compensation to the control operators of station W1AW. As a consequence, we are today issuing a Notice of Proposed Rule Making in a separate proceeding which would allow in certain instances involving club stations the compensation of control operators. We are also herein granting a waiver of the necessary rules to the licensee of station W1AW to allow the station to continue to operate pending the final action on our Notice of Proposed Rule Making. Any other club station providing similar services as W1AW may apply for a similar waiver. Such requests will be handled on a case by case basis.

11. The American Radio Relay League and several other individuals filed comments which suggested that the Commission adopt a rule specifically prohibiting communications for any purpose or activity which is contrary to federal, state, or local law. We find that this suggestion as it applies to any radio communications including third party traffic, has substantial merit. Therefore, with certain editorial changes, we are adopting their proposal as §97.116.

12. Authority for the rule changes adopted herein is contained in Sections 4(i) and 303 of the Communications Act of 1934, as amended.

13. The Commission finds that further Public Notice in regard to the subject matter of this Report and Order is unnecessary. Notice of the general subject matter and of the issues involved was previously given and extensive comments from interested parties have been received and given careful consideration. No public interest would be served by further notice and public participation in this matter.

14. IT IS ORDERED, effective December 1, 1972, that Part 97 of the Commission's Rules is amended as set forth in the attached Appendix.

15. IT IS FURTHER ORDERED, that a waiver of §§97.112 and 97.114(b) is GRANTED to the licensee of amateur station W1AW.

16. IT IS FURTHER ORDERED, that RM-1687 is denied to the extent that it is inconsistent with the rules adopted in this Report and Order and that this proceeding is TERMINATED

Federal Communications Commission
Ben F. Waple
Secretary

NOTE: Rules changes herein will be covered by T.S. VI(72)-1.

APPENDIX

Part 97 of the Commission's Rules is amended as follows:

1. Section 97.3(w) and (x) is added as follows:

§97.3 *Definitions*

(w) *Third party traffic.* Amateur radiocommunication by or under the supervision of the control operator at an amateur radio station to another amatuer radio station on behalf of any one other than the control operator.

(x) *Emergency communication.* Any amateur radio communication directly relating to the immediate safety of life of individuals or the immediate protection of property.

2. Section 97.39 is amended to read as follows:

§97.39 *Eligibility of corporations or organizations to hold station license.* An amateur station license will not be issued to a school, company, corporation, association, or other organization, except that in the case of a bona fide amateur radio organization or society, a station license may be issued to a licensed amateur operator, other than the holder of a Novice Class license, as trustee for such society.

3. Section 97.79(d) is amended to read as follows:

§97.79 Control operator requirements

(d) The licensee of an amateur radio station may permit any third party to participate in amateur radio communications from his station, provided that a control operator is present and continuously monitors and supervises the radiocommunication to insure compliance with the rules.

4. Section 97.114 is added to read as follows:

§97.114 *Third party traffic.*

The transmission or delivery of the following amateur radiocommunication is prohibited:

(a) International third party traffic except with countries which have assented thereto;

(b) Third party traffic involving material compensation, either tangible or intangible, direct or indirect, to a third party, a station licensee, a control operator, or any other person.

(c) Except for an emergency communication as defined in this Part, third party traffic consisting of business communications on behalf of any party. For the purpose of this section business communication shall mean any transmission or communication the purpose of which is to facilitate the regular business or commercial affairs of any party.

4. Section 97.116 is added as follows:

§97.116 *Amateur radiocommunication for unlawful purposes prohibited.* The transmission of radiocommunication or messages by an amateur radio station for any purpose, or in connection with any activity, which is contrary to Federal, State, or local law is prohibited.

Notice of Proposed Rule Making
Docket 19605

In the matter of Amendment of Part 97 to allow the compensation in certain instances of control operators of stations operating in the Amateur Radio Service and modification of the logging requirements regarding third party communications.

Adopted: October 5, 1972

Released: October 11, 1972

By the Commission: Commissioner Johnson dissenting; Commissioner Reid absent.

1. In our Report and Order adopted today in Docket 19245 we established rules regarding the type of third party traffic that amateur licensees may properly handle including the compensation of control operators for transmitting such messages. The Commission hereby gives Notice of Proposed Rule Makin concerning the collateral issues of compensation of amateur club station control operators and possible relaxation of the logging requirement for third party communications.

2. The American Radio Relay League operates an amateur station that is engaged in multiple address point to point communications. They broadcast bulletins, informational matter, and code practice of particular significance to amateur licensees. This type of communication is highly beneficial to both amateur operators and the Amateur Radio Service and should be encouraged.

3. The equipment used by these stations is in many instances as complex as a standard or FM broadcast station. As a result, it is impractical to operate these stations with volunteers, especially if the station operates for a substantial period each week.

4. The Commission is considering two different solutions. First, we are proposing specific rules which are designed to allow any bona fide amateur organization to operate a station and provide reasonable compensation to the control operator when the station transmits material solely related to the Amateur Radio Service. The rules, which will be designated as §97.112(b) set forth specific criteria which a club station must meet in order to provide compensation to their operators. These criteria are designed to insure that stations compensating their operators are in fact en-

Continued on page 146.

FCC continued from p. 140.

gaged in providing a service to a significantly large sement of amateur licensees. Another solution would be to create a new class of amateur station which will be required, before they will be licensed, to make a showing similar to our proposed rules contained in the attached appendix. Comments are invited regarding these two possible solutions and any other proposals regarding this type of operation.

5. Section 97.103(b)(3) requires that an amateur radio station log include a notation of third party messages sent or received, including names of all participants and a brief description of the message content. The Commission invites comments regarding the usefulness of this requirement and whether it should be modified or deleted.

6. Authority for the proposed rule changes contained herein is contained in §§4(i) and 303 of the Communications Act of 1934, as amended.

7. Pursuant to applicable procedures set forth in Section 1.419 of the Commission's Rules, an original and 14 copies of all material requested by this proceeding should be submitted on or before December 20, 1972, and reply comments on or before January 3, 1973. All relevant material will be considered by the Commission. In reaching its decision in this proceeding, the Commission may also take into account other relevant data before it in addition to the specific data invited by this Notice. Responses will be available for public inspection during regular business hours in the Commission's Public Reference Room at its headquarters, 1919 M Street, N.W., Washington, D.C.

Federal Communications Commission
Ben F. Waple
Secretary

APPENDIX

In Section 97.112, the present text is designated as paragraph (a) and a new paragraph (b) is added to read as follows:

§97.112 *No remuneration for use of station*

(b) Control operators of a Club Station may be compensated when the club station is operated primarily for the purpose of conducting amateur radiocommunication to provide code practice transmissions intended for persons learning or improving proficiency in the International Morse Code, or to disseminate information bulletins consisting solely of subject matter having direct interest to the Amateur Radio Service provided:

(1) The station is operated weekly for a period of at least 40 hours;

(2) The station schedules operations on all allocated high frequency amateur bands using reasonable measures to maximize coverage;

(3) The schedule of normal operating times and frequencies is published at least 30 days in advance of the actual transmissions;

I am in search of information concerning a surplus U.S. Navy receiver. Type CAY 46077 2–20 MCS in 4 Bands. A unit of RBM-4 Radio Equipment manufactured for the Navy Department – Bureau of Ships. I am primarily concerned in obtaining a circuit diagram of this rcvr. and also a circuit diagram of the proper power supply for this unit. Possibly one of your readers could help me with this.

S.E. Williams VE3AZD

Islington Ontario
Canada

Re your comments on Sept 72 editorial page titled "Incentives." Ever since the "spokesman for U.S. amateurs' started promoting incentive licensing, the prime question goes begging, namely, WHAT incentive? A follow-on question is: What benefits? If new frequencies or other rewards were given to those attaining advanced licenses, the term incentive would have been valid. If the majority of amateurs ever bother to earn their extra, those narrow segments will be just as crowded as the segments allowed general and advanced. This would reduce the extra license to a mere status symbol.

I am also in favor of the amateur updating his technical knowledge (I recently did when I had to repair my transceiver – the company went out of business.) I question how much knowledge is gained and retained by marking a series of multiple choice questions. From my listening, I fail to detect any improvements attributable to incentive licensing. And like you, Wayne, I also have trouble equating higher code speed to operate on extra phone frequencies.

In sum, I hold the FCC equally culpable for buying the gold brick as peddled by that group in Hartford. Unfortunately for all of us (who were not even consulted) the ill conceived laws stay on the books as long as the good laws.

Amateur radio needs stalwarts like you, Wayne, so please don't give up the ship (73). And when you run for Director – I will move back to the first district just to vote for you.

F. E. McAllen W2SPB
Asbury Park NJ

The 5/8 wavelength vertical using a weather balloon (Oct. '72 73, p. 60) looks like a great idea for field-day expeditions, but, knowing how the high impedance end of a whip can produce lightning displays, especially when driven by a gallon at low frequencies, I wonder about the safety of persons and facilities on the ground as the then-flaming hydrogen-recommended sphere descends. Remember the Hindenburg?

TECHNICAL AID GROUP

The Technical Aid Group is a group of hams who have indicated a willingness to share their knowledge and skills with others. They have volunteered to be of service to fellow hams and do so without compensation. If you have a technical question, look over the list to see who has competency in the area of your question. For many of the TAG members, descriptions of all areas of expertise would be lengthy, so an abbreviated description is given. When stating your problem, give as much information as possible and clearly state the difficulty. Enclose a SASE for reply.

For those hams who have a desire to share, the TAG is the thing for you. Send a brief note requesting the membership form, fill it in and send it back. It asks a few questions about your qualifications, and there is a check-list to indicate your fields of competence. These cover all modes currently used by hams, antenna design and theory, transmitter and receiver design for HF, VHF, and UHF, logic, ICs, general help, and other areas. As more members are added, their names and addresses will be published.

This list is not complete, but represents those former TAG members who have responded to a recent mailing and have expressed a desire to continue in the program. Comments from them indicate that they have enjoyed helping and all have been contacted frequently for advice.

Robert Perlman WB2VRW, 3 Josten Place, Hudson NY 12534. Electrical engineering student. Will help with Novice transmitters and receivers, and any help for beginning hams.

Thomas Laffin W1FJE, Box 133, Hillsboro NH 03244. Radio communications technician. Special aid to ex-CBers and those who need terms in easily understood terms; aid to Novices and Techs interested in MARS, RACES, CD, and CAP; how to build and scrounge parts; assistance on ham history, ATV, microwave, and general help.

Theodore Cohen W4UMF, 8603 Conover Pl., Alexandria VA 22308. Geophysicist. Specially prepared to answer questions about SSTV and ATV.

J. Bradley Flippin K6HPR, 116 Montecito Ave., Apt. M., Monterey CA 93940. Electronic engineer. Help with RTTY, data processing and programming, general.

Ira Kavaler WA2ZIR, P.O. Box 54, Flatbush Sta., Brooklyn NY 11226. Electrical engineer. Assistance offered in theoretical aspects of electricity and electronics from dc to UHF, design of equipment, computer programming, and signal circuit (failsafe) design.

Jon Teich WB2JAE, 22 Olden Rd., Edison NJ 08817. High school student. Novice and others, transmitter and receiver problems, logic, and general.

David Felt WB6ALF, P.O. Box 261, Sierra Madre CA 91024. Electronics engineer. Qualified help in logic, digital and analog design, solid state, AM and TV.

Robert Groh WA2CKY, 65 Roxborough Rd., Rochester NY 14619. Communications engineer. Bob can lend a hand in HF and VHF transmitter and receiver design as well as solid-state logic and digital techniques.

Carl Miller WA6ZHT, 334 Paragon Ave., Stockton CA 95207. Computer technician. Carl's specialty area is solid-state QRP.

George Daughters WB6AIG, 1560 Klamath Dr., Sunnyvale CA 94087. Research associate. HF transmitter and receiver, SSB, and solid state, are George's fields.

D. Hausman VE3BUE, 267 Northcrest Pl., Waterloo, Ontario, Canada. Student. Novice transmitter and receiver problems as well as logic, digital techniques and ICs.

Hugh Wells W6WTU, 1411 18th St., Manhattan Beach CA 90226. Electronics instructor. Hugh can help with AM, Novice problems, VHF-UHF receivers and converters, solid state, test equipment, FM and repeaters, and general help.

Charles Hill WA7LQO, 4005 Campbell St., Baker OR 97814. Student. TV, Novice transmitter problems, and logic.

John Perhay WAØDGW, Route 4, Owatonna MN 55060. EE technician. John will help with RTTY, AM, SSB, Novice gear, HF transmitters and receivers, solid state, ICs, and test equipment.

Jim Jindrick WA9QYC, 801 Florence Ave., Racine WI 53402. Consulting engineer. General help as well as HF, VHF, and UHF antennas, transmitters, and receivers.

William Welsh W6DDB, 2814 Empire Ave., Burbank CA 91504. Electronic engineer. Beginner's problems, code instruction, theory and regulations.

Ken Knecht K8VNT, Box 39, Clintondale NY 12515. Television engineer. TV, logic, and digital techniques.

Tom O'Hara W6ORG, 10253 E. Nadine St., Temple City CA 91780. Communications engineer. RTTY, TV, AM, SSB, VHF antennas, transmitters and receivers for HF through UHF, solid state, and general help.

Bruce Creighton WA5JVL, 2517 Metairie Ct., Metairie LA 70002. Electrical engineer. Antennas, Novice problems, solid state, logic, digital techniques, test equipment, and general help.

Tom Borok WB2PFY 215-33 23 Rd., Bayside NY 11360. Student. Tom is especially qualified to help Novices with their problems with transmitters and receivers, HF and VHF antennas, HF receivers, test equipment, and surplus, Morse code instruction.

Roger Taylor K9ALD, 2811 William St., Champaign IL 61820. Engineer. Roger is adept with AM, SSB, antennas, solid state, logic and digital techniques, ICs, test equipment, and other general help.

Orris Grefsheim WA6UYD, 1427 W. Park St., Lodi CA 95240. TV technician. Orris is capable of assisting in all fields of amateur work, DC through UHF, logic as well as Novice help.

John Allen K1FWF, 112 Edgemoor Lane, Ithaca NY 14850. Technical director. John's areas of assistance are VHF and UHF antennas, receivers, and transmitters, solid state and digital techniques, ICs, and SSB.

...AND MORE!

I was very interested in the WWVB receiver article in the latest issue, even though so far as I know WWVB cannot ordinarily be heard in this area.

I have been trying without any success to find details of LORAN C on 200 kHz. I made a trip to the Coast Guard Station at Woods Hole, but nobody there would tell me anything.

Can you tell me where to get info on this? ditto for OMEGA system?

I should be most appreciative of any help you can give me.

Bill Hunt
336 Marion Road
Middleboro MA 02346

Does anyone have the information Bill needs?

Having trouble with buzzes, yoops, and music from that nearby broadcast station?

Well, put on your old shoes, coveralls, and take a swig out of that hidden bottle of bug juice, and crawl under the house with a flashlight, some bare wire, a file, and a wiping rag or two.

If you find pipes and conduit crisscrossing, or laying upon one another, pry them apart, and put something in between, such as friction tape or old newspapers.

If the pipes can't be pried apart, bind them together wherever they touch. It's usually a dirty job, but will probably put a stop to your trouble.

It's called cross-modulation, and if you are getting music from that pesky broadcast station, you can often stop it for good, and your DX cards from the other side of the world might arrive more often.

In the November 1972 *Stereo Review* there is an article by one Peter Sutheim on "Radio-Frequency Bugs in your Audio System." The article is apparently quite good as far as technical solutions are concerned, but portrays amateurs in the same bag with CBer's as "casual" users of the airwaves who "may not give a damn." I would hope that you and others could find the time to read the article – it reveals the kind of PR problems that we must contend with. I have written a short, polite letter to Mr. William Anderson, the editor of *SR*, to clarify Sutheim's misconceptions and would strongly encourage as many other hams as care about their avocation to do likewise.

If we can't beat RFI, it's going to beat us – for good.

William M. Klykylo WA8FOZ

I have read with great interest, W9JT's "Petition" in the October issue. His suggested allocations of the amateur frequencies suggest three things to me:

1. HIS favorite mode of transmission is SSB.
2. He seems to think that amateurs have no purpose except to chew the fat.
3. He is an extremely selfish indi vidual.

His impression of amateur service is that hams are nothing more than a lot of people competing for spectrum space to talk, largely about nothing. Unfortunately, a large number of hams have the same impression. They, and Mr. Fyler, should comply with the FCC requirement that amateur operators be familiar with the domestic and international regulations governing amateur service. Specifically, they should read that part of the Geneva radio regulations where the amateur service is defined, "A service of self training and technical investigations carried on by amateurs . . ." This very definition would be completely invalidated, were Mr. Flyer's recommendations or any like them ever adopted.

The present amateur service knows many modes of transmission. Consequently amateur radio has always served as a source of self trained personnel for all phases of the communications industry. In spite of the great popularity of SSB fone, all the present modes of transmitting information have, and always will have, their place. For example, AM phone is still the prime means of voice transmission outside of the amateur service. (Name one commercial broadcasting station that uses suppressed carrier single sideband.) FM phone holds a close second. There are still a great many commercial and government CW stations. How can there be any self training if these still widely-used techniques are closed to the amateur?

In the amateur service itself, AM phone still offers audio quality far superior to SSB. I am yet to hear the SSB station that, even on equipment designed for SSB, sounds any better than a constipated duck. Phone nets are, in fact, handicapped when they use SSB since every station must be within a few Hz of net frequency – a difficult thing to achieve, even with today's sophisticated equipment. Without intending to degrade the many capable operators who utilize SSB, I must also say that I have run across many operators who now don't know how to properly tune in an AM signal and whose equipment gives decidedly inferior performance when receiving an AM signal. On the other hand, SSB certainly is the better medium for casual conversation.

For handling third-party traffic, CW cannot be beat. I won't elaborate on this; I will merely suggest listening in to a phone net, then to a CW net.

RTTY is also superior to phone for message traffic, although, because of its extreme complexity, I feel it is still second to CW.

If Mr. Fyler's recommendations were ever adopted, the ham bands would shortly become more polluted than Lake Erie. His statement that "It is imperative that SSB fone have the right of way over CW . . ." betrays him as the sort that would eventually degenerate amateur radio to the point of eliminating CW altogether, leaving his favorite medium in exclusive control of the entire amateur spectrum and cluttering it with the multitudes of individuals who today are crying in their beer that they can't learn the code which, to date, millions of eleven-year-old boy scouts have learned. We've kooks enough on the air without that lot.

I recently received a letter from WA4RMF asking for an article enumerating the contributions of amateurs to progress in the electronic industry. No mere article, not even a full-sized volume, can do justice to this subject. The better engineers and technicians in every electronic firm in the country, and most commercial radio and TV stations are hams, to say nothing of the hams that pervade the telephone companies, and recording studios. The bulk of them got their start as amateurs. I am indebted to my hobby for a fifteen-year career in electronics. I know as a fact that many ideas which are eventually absorbed in commercial and military hardware have their origins in amateur tinkering – the hams merely take them to work next day and use them. How could amateur radio ever continue this contribution to progress if it is stifled for the convenience of a large number of gasbags? Our hobby presently offers a great many outlets for public service, personal and cultural improvement, and development. It has been so from its beginning, and he that will so demean himself so as not to be endeavoring to add to his stock of knowledge and operating skill may be deemed a drone on the airways – a useless member of the fraternity and totally unworthy of being called a radio amateur.

W2FEZ

P.S. I've got a sneaky feeling you will disagree with me and support W9JT. If so, I hope you will still be man enough to print this letter.

There is some weird idea going around that I censor the stuff I print in 73, and that, therefore, everything I publish means that I agree with it. This is not the policy of 73 – this never has been the policy of 73 – and I hope it never will be the policy of 73. Just because your adored QST seems to operate this way does not mean that 73 is going to imitate them. Stuff is printed in 73 that appears to be of interest, whether I think it a bunch of bananas or not . . . wayne.
